SUPPLEMENT

TO THE THIRD EDITION OF THE

ENCYCLOPÆDIA BRITANNICA,

OR, A

DICTIONARY

OI

ARTS, SCIENCES,

AND

MISCELLANEOUS LITERATURE.

IN TWO VOLUMES.

Illustrated with Fifty Copperplates.

By GEORGE GLEIG, LL. D. F. R. S. Edin.

NON IGNORO, QUE BONA SINT, FIERI MELIORA POSSE DOCTRINA, ET QUE NON OPTIMA, ALIQUO MODO ACUI TAMEN, ET CORRIGI POSSE.——. CIGERO.

VOL. I.

Edinburgh:

PRINTED FOR THOMSON BONAR, PARLIAMENT-SQUARE;
BY JOHN BROWN, ANCHOR CLOSE, EDINBURGH.

1801.

[Entered in Stationers Hall.]

D TO THE KINGA B

STR

NT proceeds from no wain confidence in my own abilities, that I presume to solicit for this Work the Protection of a Monarcu, who is not more exalted in station, than he is distinguished, among the Potentates of the Earth, by his Taste in Literature, and his Patronage of Science and the Arts.

In conducting to its conclusion the Encretor Edia Britannica, I am conscious only of having been uniformly influenced by a sincere desire to do Justice to those Principles of Religion, Morality, and Social Order, of social the Maintenance constitutes the Glory of Your Majes TY's Reign, and will I trust, record Your Name to the latest Posterity, as the Guardian of the Laws and Liberties of Europe.

TO THE KING.

SIR.

IT proceeds from no vain confidence in my own abilities, that I presume to solicit for this Work the Protection of a Monarch, who is not more exalted in station, than he is distinguished, among the Potentates of the Earth, by his Taste in Literature, and his Patronage of Science and the Arts.

In conducting to its conclusion the Encyclopædia Britannica, I am conscious only of having been uniformly influenced by a sincere desire to do Justice to those Principles of Religion, Morality, and Social Order, of which the Maintenance constitutes the Glory of Your Majesty's Reign, and will, I trust, record Your Name to the latest Posterity, as the Guardian of the Laws and Liberties of Europe.

THE French Encyclopedie has been accused, and justly accused, of having disseminated, far and wide, the seeds of Anarchy and Atheism. If the Encyclopadia Britannica shall, in any degree, counteract the tendency of that pestiferous Work, even these two Volumes will not be wholly unworthy of Your Majesty's Patronage; and the Approbation of my Sovereign, added to the consciousness of my own upright intentions, will, to me, be an ample reward for the many years of labour which I have employed on them, and on the Volumes to which they are Supplementary. I am,

SIR,

Your Majesty's

Most faithful Subject,

And most devoted Servant,

STIRLING, Dec. 10. 1800.

GEORGE GLEIG.

ADVERTISEMENT.

IT would ill become me to difmiss these Volumes from my hands without acknowledging that, from many of the most valuable disquisitions which they contain, I can claim no other merit than that of having ushered them into the world.

Those who have read, and who understand, the articles in the Encyclopædia Britannica, which were furnished by Protessor Robison of Edinburgh, can hardly need to be informed, that to the same eminent philosopher I am indebted for the valuable articles Arch, Astronomy, Carpentry, Centre, Dynamics, Electricity, Impulsion, Involution and Evolution of Curves, Machinery, Magnetism, Mechanics, Percussion, Piano-Forte, Centre of Position, Temperament in Music, Thunder, Musical Trumpet, Tschirnhaus, and Watchwork, in this Supplement. Of a friend and co-adjutor, whose reputation is so well established as Dr Robison's, I am proud to say, that, while I looked up to him, during the progress of this Work, as to my master in mathematical and physical science, I found him ever ready to support, with all his abilities, those great principles of religion, morality, and social order, which I felt it my own duty to maintain.

To Thomas Thomson, M. D. of Edinburgh, a man of like principles, I am indebted for the beautiful articles Chemistry, Mineralogy, and Vegetable, Animal, and Dyeing Substances; of which it is needless for me to say any thing, since the Public seems to be fully satisfied that they prove their author eminently qualified to teach the science of chemistry.

The account of the French Revolution, and of the wars which it has occasioned, has been continued in this Supplement by the same Gentlemen by whom that account was begun in the Encyclopædia; and, owing to the cause assigned in the article, probably with the same merits and the same defects.

My thanks are due to Dr William Wright for his continued kindness in communicating much curious botanical information: and to Mr Professor Playsair of the university of Edinburgh, for lending his assistance, occasionally, in the mathematical department; and for writing one beautiful article in that science, which is noticed as his in the order of the alphabet.

In compiling this Supplement, I have made very liberal use of the most respectable literary and scientific journals, both foreign and domestic; of all the late accounts of travels and voyages of discovery, which have obtained, or seem indeed to deserve, the regard of the Public; of different and opposite works on the French revolution, and what are emphatically called *French principles*; and even of the most approved Dictionaries, scientific and biographical. From no Dictionary, however, have I taken, without acknowledgment, any articles, except such as are floating everywhere on the surface of science, and are the property, therefore, of no living author.

AFTER all my labour and industry, which, whatever be thought of my other merits, I am conscious have been great, no man can be more sepsible than myself, that the Encyclopædia Britannica, even with the addition of this Supplement, is still impersect. It would continue to be so, were another Supplement added to this by the most learned and laborious man on earth; for persection seems to be incompatible with the nature of works constructed on such a plan, and embracing such a variety of subjects.

No candid reader will suppose that, by expressing myself thus, I mean to censure the plan of the Encyclopædia Britannica in particular; for, to the general excellence of that plan I have elsewhere borne my testimony, which I have yet seen no reason to retract. Experience has indeed led me to think, that it is susceptible of such improvements as would enable the principal Editor to carry the work neurer to perfection, even with less trouble to himself; but the purchasers of the third edition and this Supplement need not regret the want of those improvements, for they are such as sew would differn, who have not paid the same attention that I have done to dictionaries of arts, sciences, and literature.

Before I take leave of the reader, I must account for the omission of one or two articles (chiefly biographical) which I had given him reason to expect in these volumes. It was my intention at first to introduce into the Supplement articles on every subject which had been admitted into the Encyclopædia itself; and hence in the first supplementary volume will be found biographical sketches of men whose characters, though in some respects remarkable, have very little connection with science, arts, or literature. From this part of the original plan I was foon obliged to deviate. So many applications were made to me to infert accounts of perfons who, whatever may have been their private virtues, were never heard of in the republic of letters, that I was under the necessity of excluding from the second volume the lives of all such as had not either been themselves eminent in literature, or in some liberal art or science, or been conspicuous as the patrons of science, arts, and literature, in others. Hence the omission of the life referred to from Aubigne in the first volume, and of one or two others to which references are made in the tame way. The life of Mr James Hay Beattie of Aberdeen, whose originality of genius, ardent love of virtue, and early and extensive attainments in science and literature, raise him almost to the eminence of BARRETIER, of whom we have so pathetic an account from the pen of Johnion, I omitted with regret; but I thought not myself authorized to publish what his tather had then only distributed among a few particular friends. For the omission of the life of Soame Jenyns I can make no apology: it was the consequence of forgetfulnefs.

For the errors of these two volumes, whether typographical or of a nature more important, I have perhaps no occasion to solicit greater indulgence than will be voluntarily extended to me by a generous public. The progress, however, of science, and of the revolutionary events in Europe, has been such, since great part of them was printed, that I must request the reader, in justice to myself, to proceed directly from the article Galvanism to Torpedo, and from Revolution to the life of Marshal Suworow.

UNDER the title Translation, both in the Encyclopædia and in the Supplement, expressions are made use of, which may lead the reader to suppose that Mr Fraier Tytler was indebted for the general laws of the art, which he so ably illustrates, to Dr Campbell's Preliminary Differtations to his Translation of the Gospels. It is but justice to declare my perfect conviction, as it was that of Dr Campbell himself, that Mr Tytler and he were equally intitled to the merit of having discovered those laws; and that however coincident in opinion, neither of them, when composing their separate works, had the sinallest suspicion that the other had ever employed his thoughts on the subject. The only difference seems to have been in the mode of their discovery: Mr Tytler having deduced the laws of the art by regular analytical inference from his own description of a perfect translation; whereas Dr Campbell appears to have fortunately discovered them without that process of deduction.

NCYCLOPÆDIA

BACISCUS, in architecture, the fame with A-BACUS; for which, fcc Encyclopædia.

ABATIS, or ABATTIS, is, in military language, the name of a kind of retrenchment made of felled trees. When the emergency is fudden, the trees are mercly laid lengthwife beside each other, with their branches pointed towards the enemy, to prevent his approach, whilst the trunks serve as a breastwork before those by whom the abatis is raifed. When the abatis is meant for the defence of a pass or entrance, the boughs of the trees are generally stripped of their leaves and pointed; the trunks are planted in the ground; and the boughs are interwoven with each other. It is needless to add, that the closer the trees are laid or planted together, the more secure is the defence which they afford; and it, when they are planted, a small ditch be dug towards the enemy, and the earth thrown up properly against the lower part of the abatis, it will be very difficult to pass it if well defended .- Simes's Military Guide.

ABBREVIATION of FRACTIONS, in arithmetic and algebra, is the reducing of them to lower terms; which is done by dividing the numerator and denominator by fome number or quantity which will divide both without leaving a remainder of either.

ABERRATION, in optics (in Encycl.), refers the reader to the article Optics, no 17, 136, 173. It should have referred him to Optics, no 17, and 251-

ABERRATION of the Vifual Ray, is a phenomenon, of which, though some account of it has been given in the Encyclopædia (fee ABERRATION, in aftronomy; and the article Astronomy, no 337.), one of the most candid of our correspondents requires a fuller explanation. If fuch an explanation be requifite to him, it must be much more fo to many others; and we know not where to find, or how to devise, one which would be more fatisfactory, or more familiar, than the following by Dr

"This effect (fays he) may be explained and familiarized by the motion of a line parallel to itself, much after the manner that the composition and resolution of forces are explained. If light have a progressive motion, let the proportion of its velocity to that of the earth in her orbit be as the line BC to the line AC; then, by the composition of these two motions, the particle of light will feem to describe the line BA or DC, Suppl. Vol. I. Part I.

instead of its real course BC; and will appear in the di-Aberration rection AB or CD, instead of its true direction CB. So that if AB represent a tube, carried with a parallel, motion by an observer along the line AC, in the time that a particle of light would move over the space BC, the different places of the tube being AB, ab, cd, CD; and when the eye, or end of the tube, is at A, let a particle of light enter the other end at B; then when the tube is at ab, the particle of light will be at e, exactly in the axis of the tube; and when the tube is at cd, the particle of light will arrive at f, still in the axis of the tube; and, lastly, when the tube arrives at CD, the particle of light will arrive at the eye or point C, and confequently will appear to come in the direction DC of the tube, instead of the true direction BC: and so on, one particle succeeding another, and forming a continued stream or ray of light in the apparent direction DC. So that the apparent angle made by the ray of light with the line AE is the angle DCE, instead of the true augle BCE; and the difference BCD, or ABC, is the quantity of the aberration."

ABERRATION of the Planets, is equal to their geocentric motion, or, in other words, to the space which each appears to move as feen from the earth, during the time that light employs in passing from the planet to the eye of the observer. Thus the sun's aberration in longitude is constantly 20", that being the space actually moved by the earth; but apparently by the fun in 8 minutes and 7 feconds, the time in which light passes from the fun to the cartle. If then the distance of any planet from the earth be known, the time which light employs in passing from the planet to the earth must likewise be known; for as the distance of the sun is to the distance of the planet, so is 8 minutes and 7 seconds to that time; and the planet's geocentric motion in that time is its aberration, whether it be in longitude, latitude, right ascention, or declination. See ASTRONO. my in this Supplement.

ABOAB, cesses levied, in India, under different de-

nominations, beyond the standard rent.

ABSCISS, ABSCISSE, or Abscissa, is a part cut off from a straight line, and terminated at some certain point by an ordinate to a curve; as AP (fig. 2.), or Plate II BP (fig. 3.) The absciss may commence either at the vertex of the curve, or at any other fixed point; and it may be taken either upon the axis or upon the dia-

Absorption, meter of the curve, or upon any other line drawn in a Absurdum. given position. Hence there are on the same given line or diameter an infinite number of variable absciffes, terminated all at one end by the fame fixed point. the common parabola (fig. 4.), each ordinate PQ has but one abscis AP. In the elipse or circle (fig. 2.), the ordinate has two absciffes lying on the opposite sides of it. In general, to each ordinate a line of the fecond kind, or a curve of the first kind, may have two abscisfes; a line of the third order, three; a line of the fourth order, four; and fo on.

ABSORPTION, in ANATOMY and Physiology, has been fufficiently explained under these articles in the Encyclopædia; but there is another absorbing power possessed by different substances, which is worthy of attention, because it is only by our knowledge of it that we can adapt our clothing to the various climates of the earth. The power to which we allude is that of different fubstances: fuch as wool, cotton, filk, and linen, to absorb or attract moisture from the atmosphere. On this subject the reader will find some very instructive experiments detailed (in Encycl.), where perhaps he may not have looked for them, under the title FLANEL.

ABSURDUM, a term made use of by mathematicians when they demonstrate any truth, by showing that its contrary is impossible, or involves an absurdity. Thus, Euclid demonstrates the truth of the fourth proposition of the first book of his Elements, by showing that its contrary implies this obvious abfurdity-" that two straight lines may inclose a space."

This mode of demonstration is called reductio ad abfurdum, and is every whit as conclusive as the direct method; because the contrary of every falsehood must be truth, and of every truth, falsehood.

The young geometrician, however, does not, we believe, feel himself fo perfectly fatisfied with a demonstration of this kind, as with those which, proceeding from a few felf-evident truths, conducts him directly, by necessary consequences, to the truth of the proposition to be proved. The reason is, that he has not yet learned to diffinguish accurately between the words false and impossible, different and contrary. Many different affertions may be made relating to the same thing, and yet be all true or all falie; but it is impossible to make two affertions directly contrary to each other, of which the one shall not be true and the other false. Thus, " fnow is white," "fnow is cold," are different affertions relating to the fame thing, and both true; as, " fnow is black," "fnow is red," are both false: but let it be remembered, that of the first and fecond, and of the third and fourth of these affertions, neither is directly contrary to the other; nor is any one of them, abstractly considered, impossible, or such as a blind man, who had never felt nor heard of fnow, might not believe upon ordinary testimony. But were all the men in Europe to tell a native of the interior parts of Africa that fnow is a thing at once white and not white, cold and not cold, the woolly-headed favage would know as well as the most fagacious philosopher, that of these contrary affertions the one must be true and the other must be falle. Just fo it is with respect to Euclid's fourth proposition. Had he proved its truth by showing that its contrary involves this proposition, that "the diagonal of a square is commensurate with its fide," the skilful geometrician would indeed have admitted the demonstration, because

he knows well that the diagonal of a fquare is not com- Accelerated menfurate with its fide; but the tyro in geometry would have been no wifer than before. He knew from the beginning, that the proposition and its contrary cannot both be true; but which of them is true, and which false, such a demonstration could not have taught him, because he is ignorant of the incommensurability of the diagonal and tide of a square. No man, however, is ignorant, that two straight lines cannot inclose a space; and tince Euclid shows that the contrary of his propofition implies this abfurdity, no man of common fense can entertain a doubt but that the propolition itself must be true.

ACCELERATED MOTION. ? See (Encycl.) Ac-ACCELERA'TING FORCE. CELERATION; and MECHANICS, Sect. VI .- and (this Supplement) - Dy-

ACTION is a term which has been fufficiently explained in the Encyclopædia; but fince that article was written, questions have been agitated respecting agents, agency, and action, which, as they have employed some of the most eminent philosophers of the age, and are connected with the dearest interests of man, are certain-

ly entitled to notice in this place. It is the opinion of Dr Reid, and we have adopted it (see METAPHYSICS, no 109, &c. Encycl.), that no being can be an agent, or perform an action, in the proper sense of the word, which does not possess, in some degree, the powers of will and understanding. If this opinion be juit, it is obvious, that what are called the powers of nature, such as impulse, attraction, repulsion, elasticity, &c. are not, strictly speaking, powers or causes, but the effects of the agency of some active and intelligent being; and that physical causes, to make use of common language, are nothing more than laws or rules, according to which the agent produces the effect.

This doctrine has been controverted by a writer whose acuteness is equalled only by his virtues; and we shall confider some of his objections to it in another place (see CAUSE): but a question of a different kind falls under our present consideration; and perhaps the answer which we must give to it, may go far to remove the objections to which we allude.

Can an agent operate where, either by itself or by an instrument, it is not present? We think not; beeause agency, or the exertion of power, must be the agency of something. The constitution of the human mind compels us to attribute every action to some being; but if a being could act in one place from which it is absent, it might do the same in a second, in a third, and in all places; and thus we should have action without an agent: for to be absent from all places is a phrase of the same import as not to exist. But if a living and intelligent being cannot act but where it is either inmediately or instrumentally present, much less surely can we attribute events of any kind to the agency of an abfent and inanimated body. Yet it has been faid, that " we have every reason, which the nature of the subject and of our own faculties can admit of, to believe, that there are among things inanimate fuch relations, that they may be mutually causes or principles of change to one another, without any exertion of power, or any operation of an agent, firstly fo called. Such relations, for aught that we know, may take place among bodies at great distances from one another, as well as among

Action. bodies really or seemingly in actual contact; and they may vary both in degree and in kind, according to the distances between the bodies."

That any thing should be a cause or principle of change to another, without the exertion of power or the operation of an agent, appears to us a palpable contradiction; and we could as easily conceive any two sides of a triangle to be not greater than the third fide, as reconcile fuch a proposition to that faculty of our minds by which we diftinguish truth from falsehood. When we see one body the apparent cause of change in another body, we cannot possibly entertain a doubt of the exertion of power; but whether that power be in the bedy apparently producing the change, or in a diffinct agent, is a queltion to which an answer will not so readily be found. That it is in a distinct agent, we are strongly inclined to believe, not only by the received doctrine concerning the inertia of matter, which, though it has been frequently controverted, we have never feen difproved, but much more by confidering the import of an observation trequently introduced to prove the direct contrary of our belief. "We cannot be charged (fays the writer whom we have just quoted) with maintaining the absurdity, that there may be an effect without a cause, when we refer the fall of a stone to the ground, and the ebbing and flowing of the fea, to the influence of the earth on the stone, and of the sun and moon on the ocean, according to the principle of general gravitation."

We admit the truth of this observation, provided the influence of the fun and moon on the ocean be possible; but, to us at least, it appears impossible, and is certainly inconceiveable. The influence of the fun and moon can here mean nothing but the action or operation of the fun and moon; but if thefe two bodies be inanimate, they cannot act at all, in the proper sense of the word; and whatever they be, it is obvious that they cannot act immediately on an object at fuch a distance from them as the earth and the ocean. If they be the agents, they must operate by an instrument, as we do when moving objects to which our hands cannot reach; but as it has been shown elsewhere (see METAPHYSICS, no 199. and OPTICS, nº 63. Encycl.), that neither air, nor æther, nor any other material instrument which has yet been thought of, is fufficient to account for the phenomena of attraction and repulsion, it is furely much more rational to conclude, that the ebbing and flowing of the fea are produced, not by the influence of the fun and moon, but by the power of some distinct agent or

What those agents are, we pretend not to fay. If the Supreme Being himfelf be the immediate author of every change which takes place in the corporeal world, it is obvious that he acts by fixed rules, of which many are apparent to the most heedless observer, whilst the discovery of others is reserved for the reward of the judicious application of the faculties which he has given us. If he employs inferior agents to carry on the great operations of nature, it is furely not difficult to conceive that the powers of those agents which were derived from him, may by him be restrained within certain limits, and their exercise regulated by determined laws, in fuch a manner as to make them produce the greatest benefit to the whole creation. Nor let it be thought an objection to this theory, that the changes

which take place among bodies at great distances from Action each other, vary both in degree and in kind according Aerology. to the distances; for this variation, which we acknowledge to be a fact, appears to us wholly unaccountable upon any other hypothesis than that which attributes the different changes to agents distinct from the bodies themselves. Did we perceive all the particles of matter, at all distances, tending towards each other by a fixed law, we might be led to consider mutual attraction as an effential property of that fubstance, and think no more of inquiring into its cause, than we think of inquiring into the cause of extension. But when we find that the same particles, which at one distance seem to attract each other, are at a different distance kept afunder by a power of repulsion, which no force, with which we are acquainted, is able to overcome, we cannot attribute the principle or cause of these changes to brute matter, but must refer it to some other agent ex-

erting power according to a fixed law.

It is the fashion at present to despife all metaphysical enquiries as abstruse and useless: and on this account we doubt not but fome of our readers will turn away from this disquisition with affected disgust, whilst the petulant and unthinking chemift, proud of possessing the fecrets of his fcience, will deem it superfluous to inquire after any other natural agents than those of which he has been accustomed to talk. But with the utmost respect for the discoveries made by modern chemists, which we acknowledge to be both numerous and important, we beg leave to observe, that though these gentlemen have brought to light many events and operations of nature formerly unknown, and have shown that those operations are carried on by established laws. none of them can fay with certainty that he has difcovered a fingle agent. The most enlightened of them indeed pretend not to have discovered in one department of fcience more than Newton discovered in another; for they well know that agents and agency cannot be fubjected to any kind of physical experiments. Our very notions of these things are derived wholly from our own consciousness and reflection; and when it is considered what dreadful consequences have in another country refulted from that pretended philosophy which excludes the agency of mind from the universe, it is furely time to inquire whether our consciousness and reflection do not lead us to refer real agency to mind alone. Let this be our apology both to the real and to the affected enemies of metaphysics for endeavouring to draw their attention to the present question. It is a question of the utmost importance, as well to science as to religion: and if the laws of human thought decide it, as we have endeavoured to show that they do, we may without hefitation affirm, that the impious philofophy of France can never gain ground but among men incapable of patient thinking.

ADAMAS, a name given, in aftrology, to the

ÆOLUS, in mechanics, a fmall machine invented by Mr Tidd for refreshing or changing the air in rooms when it becomes too hot or otherwife unfit for refpiration. The zolus is fo contrived as to supply the place of a fquare of glass in the window, where it works, with very little noise, like the fails of a wind-mill or a

AEROLOGY is a branch of science which was de-

Afghans tailed in the Encyclopædia at sufficient length, and according to the principles which were then generally admitted by chemists. Subsequent experiments, however, have shown, that some of those principles are erroneous, and of course that some of the opinions advanced in the article Aerology are inconfishent with facts. These opinious must be corrected; but instead of swelling this volume with a new article Aerology, we apprehend that it will be more acceptable to our scientific readers to refer them for those corrections to the article CHE-MISTRY in this Supplement.

AFGHANS, are a people in India who inhabit a province of CABUL Or CABULISTAN (fee Encycl.), and have always been connected with the kingdoms of Perfia and Hindostan. They boast of being descended of baul the first king of Ifrael; of whose advancement to the royal dignity they give an account which deviates not very widely from the truth. They fay indeed, that their great ancestor was raised from the rank of a shepherd, not for any princely qualities which he possessed, but because his stature was exactly equal to the length of a rod which the angel Gabriel had given to the prophet Samuel as the measure of the stature of him whom God had defined to fill the throne of Ifrael.

SAUL, whose descent, according to some of them, was of Judah, and according to others of Benjamin, had, they fay, two fons, BERKIA and IRMIA, who ferved David, and was beloved by him. The fons of Berkia and Irmia were Afghan and Usbec, who, during the reigns of David and Solomon, distinguished themfelves, the one for his corporeal thrength, and the other for his learning. So great indeed was the strength of Afghan, that we are told it struck terror even into demons and genii.

This hero used frequently to make excursions to the mountains, where his progeny, after his death, established themselves, lived in a state of independence, built forts, and exterminated infidels. When the felect of creatures (the appellation which this people give to Mahomet) appeared upon earth, his fame reached the Afghans, who fought him in multitudes under their leaders Khalid and Abdul Respid, sons of Walid; and the prophet honouring them with this reception-"Come, O Muluc, or Kings!" they assumed the title of Melic, which they retain to this day.

The history, from which this abstract is taken, gives a long and uninteresting detail of the exploits of the Afghans, and of their zeal in overthrowing the temples of idols. It boasts of the following monarchs of their race who have fat upon the throne of Dehli: Sultan BEHLOLE, Afghan Lodi, Sultan SECANDER, Sultan IBRAHIM, SHIR SHAH, ISLAM SHAH, ADIL SHAH Sur. It also numbers the following kings of Gaur descended of the Afghan chiefs: Solaiman Shah Gurzani, BEYAZID Shah, and KUTB Shah; besides whom, their nation, we are told, has produced many conquerors of provinces. The Afghans are sometimes called Solaimani, either because they were formerly the subjects of SOLOMON king of Ifrael, or because they inhabit the mountains of Solomon. They are likewise called Pa-TANS, a name derived from the Hindi verb Paitna "to rush," which was given to them by one of the Sultans

whom they ferved, in confequence of the alacrity with

which they had attacked and conquered his enemies.

The province which they occupy at prefent was for-

merly called Roh; and hence is derived the name of the Afghans. Robillas. The city which was established in it by the Afghans was called by them Paishwer or Paisher, and is now the name of the whole diffrict. The fects of the Afghans are very numerous; of which the principal are, Lodi, Lobouni, Sur, Seravani, Yusufzihi, Bangih, Dilazaui, Khetti, Yasin, Khail, and Beloje. They are Mufulmans, partly of the Sunni, and partly of the Shiek

Though they are great boafters, as we have feen, of the antiquity of their origin, and the reputation of their race, other Musulmans reject their claim, and consider them as of modern, and even of base, extraction.

This is probably a calumny; for it feems inconfistent with their attention to the purity of their descent-an attention which would hardly be paid by a people not convinced of their own antiquity. They are divided into four classes. The first is the pure class, confishing of those whose fathers and mothers were Afghans. The fecond class confiles of those whose fathers were Afghans and mothers of another nation. The third class contains those whose mothers were Afghans and fathers of another nation. The fourth class is composed of the children of women whose mothers were Afghans and fathers and husbands of a different nation. Persons who do not belong to one of these classes are not called Afghans.

This people have at all times diffinguished themselves by their courage, both fingly and unitedly, as principals and auxiliaries. They have conquered for their own princes and for foreigners, and have always been considered as the main strength of the army in which they ferved. As they have been applauded for virtues, they have also been reproached for vices, having sometimes been guilty of treachery, and of acting the base

part even of affaffins.

Such is the account of the Afghans published in the. fecond volume of the Afiatic Refearches. It was translated from a Persian abridgment of a book written in the Pushto language, and called The Secrets of the Afghans, and communicated by Henry Vausittart, Esq; to Sir William Jones, then president of the Asiatic Society. Their claim to a descent from Saul king of Israel, whom they call MELIC TALUT, is probably of not a very ancient date; for the introduction of the angel Gabriel with his rod, gives to the whole story the air of one of those many fictions which Mahomet borrowed from the later rabbins. Sir William Jones, however, though he furely gave no credit to this fable, feems to have had no doubt but the Afghans are descendants of Ifrael. "We learn (fays he) from ESDRAS, that the ten tribes, after a wandering journey, came to a country called Arfareth, where we may suppose they settled: now the Afghans are faid by the best Persian historians to be descended from the Jews. They have traditions among themselves of such a descent; and it is even afferted, that their families are distinguished by the names of Jewish tribes, although, fince their conversion to Islam, they studiously conceal their origin from all whom they admit not to their fecrets. The Pushto language, of which I have feen a dictionary, has a manifest resemblance to the Chaldaick; and a considerable district under their dominion is called Hazareh or Hazaret, which might eafily have been changed into the word used by ESDRAS. I strongly recommend an inquiry into the literature and history of the Afghans."

It is to co-operate with this accomplished scholar who, in the beginning of the 9th century, ascended the Almamon, Almanion that we have inferted into our Work this short account throne of the caliphs of Bagdat. He was the son of Aloc. of that fingular people; and it is with pleasure that, Harun Al-Rashid, and grandson of Almansor. His a very particular account of the Afghans has been written by the late HAFIZ RAHMAT Khan, a chief of the Robillabs, from which fuch of our readers as are oriental scholars may derive much curious information.

ALBATEGNI, an Arabic prince of Batan in Mefopotamia, was a celebrated astronomer, about the year of Christ 880, as appears by his observations. He is also called Muhammed ben Geber Albatani, Mahomet the fon of Geber, and Muhamedes Arattenfis. He made aftronomical observations at Antioch, and at Racah or Aracta, a town of Chaldea, which fome authors call a town of Syria or of Mesopotamia. He is highly spoken of by Dr Halley, as wir admirandi acuminis, as in

administrandis observationibus exercitatissimus.

Finding that the tables of Ptolemy were imperfect, he computed new ones, which were long used as the best among the Arabs: these were adapted to the meridian of Aracta or Racah. Albategni composed in Arabic a work under the title of The Science of the Stars, comprising all parts of astronomy, according to his own observations and those of Ptolemy. This work, translated into Latin by Plato of Tibur, was published at Nuremberg in 1537, with fome additions and demonfrations of Regiomontanus; and the same was reprinted at Bologna in 1645, with this author's notes. Dr Halley detected many faults in these editions .- Phil. Trans. for 1693. No 204.

In this work Albategni gives the motion of the fun's apogee fince Ptolemy's time, as well as the motion of the stars, which he makes one degree in 70 years. He made the longitude of the first star of Aries to be 183 2'; - and the obliquity of the ecliptic 23° 35'. And upon Albategni's observations were founded the Alphonsine tables of the moon's motions; as is observed by Nic.

Muler, in the Tab. Frifice, p. 248.

ALDERAIMIN, a flar of the third magnitude, in

the right shoulder of the constellation Cepheus.

ALFRAGAN, ALFERGANI, or Fargani, a celebrated Arabic aftronomer, who flourished about the year 800. He was so called from the place of his nativity, Fergan, in Sogdiana, now called Maracanda, or Samarcand, anciently a part of Bactria. He is also called Ahmed (or Muhammed) ben Cothair, or Katir. He wrote the Elements of Astronomy in 30 chapters or fections. In this work the author chiefly follows Ptolemy, using the same hypothesis, and the same terms, and frequently citing him. Of Alfragan's work there are three Latin translations, of which the last and best was made by Golius, professor of mathematics and oriental languages in the university of Leyden. This translation, which was published in 1669, after the death of Golius, is accompanied with the Arabic text, and with many learned notes on the first nine chapters, which would undoubtedly have been carried to the end, had the translator lived to complete his plan.

ALGORAB, a fixed star of the third magnitude,

in the right wing of the constellation Corvus.

ALHAZEN, an Arabian astronomer, who flourished in Spain about the beginning of the 12th century. Dee ASTRONOMY, nº 6. Encycl.

ALMAMON, was a philosopher and aftronomer,

upon the authority of Mr Vansittart, we can add, that name is otherwise written Mamon, Almaon, Almanun, Alamoun, or Al-Maimon. Having been educated with great carc, and with a love for the liberal sciences, he applied himself to cultivate and encourage them in his own country. For this purpose he requested the Greek emperors to supply him with fuch books on philosophy as they had among them; and he collected skilful interpreters to translate them into the Arabic language. He also encouraged his subjects to study them; frequenting the meetings of the learned, and affilting at their exercifes and deliberations. He caused Ptolemy's Almagest to be translated in 827, by Isaac Ben-honain, and Thabet Ben-korah, according to Herbelot, but, according to others, by Sergius, and Alhazen the fon of Joseph. In his reign, and doubtless by his encouragement, an astronomer of Bagdat, named Habash, composed three sets of astronomical tables.

Almamon himself made many astronomical observations, and determined the obliquity of the ecliptic to be then 23° 35' (or 23° 33' in some manuscripts), but Wossius says 23° 51' or 23° 34'. He also caused skilful observers to produce proper instruments to be made, and to exercise themselves in astronomical observations; which they did accordingly at Shemasi in the province of Bagdat, and upon Mount Cahus near Damus.

Under the auspices of Almamon also a degree of the meridian was measured on the plains of Sinjar or Sindgiar (or, according to some, Fingar), upon the borders of the Red Sea; by which the degree was found to contain 562 miles, of 4000 coudees each, the coudee being a foot and a half: but it is not known what foot is here meant, whether the Roman, the Alexandrian, or fome other. Riccioli makes this measure of the degree amount to 81 ancient Roman miles, which value anfwers to 62,046 French toifes; a quantity more than the true value of the degree by almost one-third. Finally, Almamon revived the sciences in the East to such a degree, that many learned men were found, not only in his own time, but after him, in a country where the fludy of the sciences had been long forgotten. This learned king died near Tarsus in Cilicia, by having eaten too freely of some dates, on his return from a military expedition, in the year 833.

ALOE DICHOTOMA, in botany, called by the Dutch Kooker-boom or Quiver-tree, is a native of the fouthern parts of Africa, and feems to be a species of the AGA-VE or American aloe (see AGAVE, Encycl.) It is thus described by LE VALLANT in his New Travels into the Interior Parts of Africa: "The aloe dichotoma rifes to the height of 25 or 30 feet; its trunk is smooth, and the bark white. When young, and the trunk not more than four or five fect long, it terminates with a fingle tuft of leaves, which, like those of the ananas, spread and form a crown, from the midst of which all its flowers iffue. As it grows older, it pushes out lateral branches, perfectly regular and fymmetrical, each of which has at its extremity a crown similar to that of the young plant. The kooker-boom thrives much better on mountains than in the plain. Inflead of long roots penetrating deep into the earth, like those of other trees, it has but a very flight one by which it is fixed to the foil. Accordingly, three inches of mould are

fufficient :

fufficient to enable it to grow upon the very rocks, and Alphonfus, attain its utmost beauty; but its root is so feeble a support, that I could throw down the largest with a single kick of my foot. The hordes on the west make their quivers of the trunk of this tree when young, whence is

derived the name given it by the planters."

It becomes not us, fitting in our chamber, to controvert a fact in natural history, of the reality of which we never had an opportunity of judging; nor would it be proper, on account of our own fcepticism, to suppress the narrative of a traveller, who corrects the narratives of former travellers in terms which nothing should have dictated but the consciousness of his own invariable ve-Yet we hope to be pardoned for expressing our furprise that, in any part of the world, trees should be found in great numbers 25 or 30 feet high, and shooting out many branches, which have yet so loose a hold of the ground, that the largest of them may be thrown down by the fingle kick of a man's foot. The reader's furprife will probably equal our's, when he is informed that the author faw one of these trees of which the trunk was ten seet four inches in circumference, whilst its branches overshadowed a space of more than 100 have kicked over. The country, according to his account, is not exempted from storms. He is himself a French philosopher. What a pity then is it that he did not explain to those, who have not had the benefit of being enlightened in that school, upon what principle of mechanics or statics the tree could refist the violence of the elements till it arrived at so enormous a size?

ALPHONSUS X. king of Leon and Castile (fee Encycl.) This prince understood astronomy, philotophy, and history, as if he had been only a man of letters; and composed books upon the motions of the beavens, and on the history of Spain, which are highly commended. "What can be more surprising (lays Mariana), than that a prince, educated in a camp, and handling arms from his childhood, should have such a knowledge of the stars, of philosophy, and the transactions of the world, as men of leifure can scarcely acquire in their retirements? There are extant some books of Alphonsus on the motions of the stars, and the hiflory of Spain, written with great skill and incredible care." In his aftronomical pursuits he discovered that the tables of Ptolemy were full of errors; and thence he conceived the first of any the resolution of correcting them. For this purpose, about the year 1240, and during the life of his father, he affembled at Toledo the most skilful astronomers of his time, Christians, Moors, and Jews, when a plan was formed for constructing new tables. This task was accomplished about 1252, the first year of his reign; the tables being drawn up chiefly by the skill and pains of Rabbi Isaac Hazan, a learned Jew, and the work called the Alphonsine Tables, in honour of the prince, who was at vait expences concerning them. He fixed the epoch of the tables to the 30th of May 1252, being the day of his accession to the throne. They were printed for the first time in 1483, at Venice, by Radtoldt, who excelled in printing at that time. This edition is extremely rare: there are others of 1492, 1521, 1545, &c.

In the Encyclopædia it is faid, that the charge of impiety brought against this prince was unjust. This was faid too confidently, because we know not of any

direct proof of his innocence. All that has been faid Alphonfue for him by Dr Hutton, one of his ablest apologists, amounts to nothing more than a high degree of probability that the charge was carried by much too far. The charge itself was, that Alphonsus affirmed, "that if he had been of God's privy council when he made the world, he would have advised him better." riana, however, fays only in general, that Alphonfus was fo bold as to blame the works of Providence, and the construction of our bodies; and he says that this flory concerning him rested only upon a vulgar tradition. The Jesuit's words are curious: " Emanuel, the uncle of Sanchez (the fon of Alphonfus), in his own name, and in the name of other nobles, deprived Alphonfus of his kingdom by a public fentence; which that prince merited, for daring feverely and boldly to censure the works of Divine Providence, and the confliustion of the human body, as tradition fays he did. Heaven most justly punished the folly of his tongue." Though the filence of fuch an historian as Mariana, in regard to Ptolemy's system, ought to be of some weight, yet we cannot think it improbable, that if Alphonsus did pass so bold a censure on any part of the universe, feet in diameter! This tree he affures that he could , it was on the celeftial sphere, and meant to glance upon the contrivers and supporters of that system. For, befides that he studied nothing more, it is certain that at that time astronomers explained the motions of the heavens by intricate and confused hypotheses, which did no honour to God, nor anywife answered the idea of an able workman. So that, from confidering the multitude of fpheres composing the fystem of Ptolemy, and those numerous eccentric cycles and epicycles with which it is embarrassed, if we suppose Alphonsus to have faid, "that if God had asked his advice when he made the world, he would have given him better council," the boldness and impiety of the censure will be greatly diminished.

Such is the apology made by Dr Hutton for this royal astronomer of Spain; and we hope, for the honour of science, that it is well founded. Still it leaves Alphonfus guilty of great irreverence of language, which is to us wholly unaccountable, if it be really true that he read the Bible fourteen times. We have feen impiety indeed break out lately from very eminent altronomers of a neighbouring nation; but these men read not the Bible, nor any thing elfe, but the dreams of the

cternal fleepers.

ALTERNATE ANGLES. See GEOMETRY (En-

cycl.), Part I. 35.

ALTERNATE Ratio, or Proportion, is the ratio of the one antecedent to the other, or of one consequent to the other, in any proportion, in which the quantities are of the fame kind. So if A: B:: C:D, then alternately, or by alternation A: C:: B: D.

ALTITUDE, PARALLAX OF, is an arch of a vertical circle, by which the true altitude, observed at the centre of the earth, exceeds that which is observed on the furface. See PARALLAX (Encycl.) and ASTRO-

NOMY (Suppl.)

ALTITUDE of the Nonagefinal, is the altitude of the 90th degree of the ecliptic, counted upon it from where it cuts the horizon, or of the middle or highest point of it which is above the horizon, at any time; and is equal to the angle made by the ecliptic and horizon where they interfect at that time.

ALTITUDE of the Cone of the Earth's or Moon's Sha- they ought to produce the same effects as pure pot affa. Alunn dow, the height of the shadow of the body made by the or ammoniac. ALUM is a falt so useful in commerce and the arts, that the knowledge of its component parts, and of the best method of preparing it, must be of importance. In the article CHEMISTRY (Encycl.), the opinions which were then held respecting its composition, and the practice which was generally followed in its preparation, have been detailed at full length; but some of these opinions have fince been controverted, and if they be erroneous, it must be expedient to vary in some degree the mode of preparation. In particular, the opinion that it is merely an excess of acid which prevents the formation of alum by evaporation of the ley, has been shown to be false by Citizen Vauquelin, who contends, of courfe, that the addition of putrid urine to the ley is

a very bad practice. This eminent chemist had long suspected, that the crystallization of alum is not prevented by an excess of acid, and that pot-ash is not of use simply to faturate this acid, but to perform an office of more importance. To bring his fuspicions to the test of experiment, he diffolved very pure ALUMINE in ful-phuric acid of equal purity, and evaporated the folution to dryness, for the purpose of expelling the superabundant acid. He then redissolved the dry and pulverulent refidue in water, and reduced the folution to different degrees of specific gravity, with a view to feize the point most favourable to crystallization; but with every possible precaution he could obtain nothing but a magma (see MAGMA), formed of faline plates, without confidence or folidity. This folution, however, though it constantly refused to afford crystallized alum alone, afforded it immediately by the addition of a few drops of the folution of pot-ash; and as he had employed these two substances in the requisite proportion, the rest of the solution, to the very end, afforded pure alum, without any mixture of fulphate of pot-

Into another portion of the same solution of pure alumine he dropped the same quantity of carbonate of foda, as he had added of that of pot-ash to the former; but no crystallization was formed, even by the help of evaporation, nor did lime and barytes produce any better effect. But if the common opinion that pot-ash, in the formation of alum, is of use only to abstract the excess of acid, be true, foda, lime, barytes, and all the fubflances which by a more powerful force would take this acid from alum, ought to give the same result. Another argument prefented itself, which seemed decifive: If the alkalis, pot-ash, and ammoniac, do nothing more than unite to the superabundant acid of the alum, the fulphates of pot ash and of ammoniac ought not to occasion any change in pure alum in its acidulated state; whereas if these alkalis enter as a constituent part into the alum, and are necessary to its existence,

To of the folution of fulphate of alumine before-mentioned diately upon which octahedral cryftals of alum were formed. The sulphate of ammoniac presented the same effect.

This refult gave still greater confirmation to his first notions, though it did not yet afford a demonstration perfectly without objection; for it might have happened that the two falts he made use of might determine the crystellization of the alum, simply by absorbing the superfluous acid, of which they are very greedy; but to determine this possible fact, he mixed in the uncrystallizable folution of alumine some sulphate of pot-ash with excess of acid, and obtained a crystallization no less abundant than with the neutral fulphate of pot-ash.

This last experiment leaves therefore no doubt with regard to the influence and mode of action of pot-ash and ammoniac in the fabrication of alum; and this action is still more strongly confirmed by the examination of the alums which have been formed by the processes above related; for in this manner it is proved that they contain confiderable quantities of the fulphates of potash and ammoniac.

These experiments led M. Vauquelin to an examination of the different alums of commerce, of which he found not one that did not afford fulphate of pot-ash, or of ammoniac, or of both. His methods of analysis are very accurate; but to detail them at length would swell this article to little purpose. To such of our readers as are not chemists they would hardly be intelligible; and the experienced chemist will devise methods of analysis for himself. It may be proper, however, to observe, that M. Vauquelin proved, to his own satisfaction, that the fulphate of pot-ash, or of ammoniac, is necessary to render alum capable of being precipitated by its earth, or to cause it to pais, as it were, to the earthy state (A). He proved likewise, that such aluminous waters as do not contain pot-ash, may remain, as long as may be defired, on their materials, without being faturated with too great a quantity of earth, or fuffering alum to precipitate.

From the whole of his experiments our author drew the following conclusions, which he confiders as of importance to the arts, to chemistry, and to natural hiflory.

1. It is not, at least in the greatest number of circumstances, the excess of acid which impedes the crystallization of alum, but it is the want of pot-ash or ammoniac: For it is difficult to imagine that the fulphuric acid could remain disengaged after so long remaining upon alumine in a state of extreme division, and always superabundant. It is true that the aluminous waters redden the vegetable tinctures; but this property is not owing to a disengaged acid. This portion of acid is a constituent part of these waters; and it appears to have more affinity with the neutral sulphate of alumine than with a new quantity of this earth at the tem. perature of the atmosphere.

2. The sulphate of pot-ash may be used, as well as pure pot-ash, to cause the crystallization of alum. It

even

(A) It may be proper to notice, that Scheele feems to have known this long before, and that he mentions it. expressly in his paper on Pyrophorus.

the aluminous waters do not really contain a disengaged acid, the pot-ash, in its combination, will precipitate a portion of alumine, and diminish the product of the boiling; whereas the fulphate of pot-ash does not produce the same effect; but if the lixiviums contain disengaged acid, which must very seldom be the case, it is not converted into alum by the fulphate of pot-ash, and is lost with regard to the product. Our author therefore is of opinion, that when the waters really contain an excels of acid, or a very oxided fulphate of iron, the use of pot-ash is preferable to that of the sulphate of pot-ash. But when economy is an object, that in many places it would be profitable to use the fulphate of pot ash; because it is a salt indirectly produced in many manufactories, where of course it may be obtained for nothing. In particular, the refidues of the distillation of aquafortis by the fulphuric acid would be excellent for this operation, and much preferable to putrid urine, because this fluid always contains phosphoric falts, which decompose a portion of the sulphate of alumine, and confiderably diminish the product.

3. Alumine cannot be used in the treatment of mother waters, as Bergman proposes. This earth is incapable of favouring the crystallization of alum, besides which, it decomposes a portion of alum by the affiftance of ebullition; in which circumstance it seizes the acid necessary to its solution, and precipitates it in the form of that powder which is called alum faturated

with its earth.

Alum.

4. Many alum ores must naturally contain pot ash, because perfect alum is often obtained from the first crystallization of new alum waters without the addition of this alkali. It is true that an objection may be made with regard to the wood used in calcining these ores, which may be supposed to have furnished the alkali; but it is not probable that the small quantity of wood employed, in comparison to the quantity of ore and the alum it affords, could supply enough of pot-ash for the

crystallization. 5. All the earths and stones which have given, or shall hereafter afford, by analysis with the sulphuric acid, perfect alum without addition of pot-ash, must contain this alkali naturally. For it is well proved, that alum cannot exist without pot-ash or ammoniac; and as there is little probability that this last should be found combined in earths or stones, unless perhaps in very rare cases, we may almost constantly be assured, when alum is obtained from any of these substances, that its formation was effected by pot-ash. The quantity of alum will immediately show in what proportion this alkali ex-

isted in the substances analysed.

6. The alum of commerce ought not to be confidered as a simple salt, but as a combination in the state of a triple and fometimes quadruple falt of fulphate of alumine; sulphate of pot-ash, or of ammoniac. Among these last we may diftinguish two species; the one without excess of acid, insoluble in water and insipid, being what is improperly called alum faturated with its own earth; and the other, which contains an excess of acid foluble in water, very fapid and aftringent, is the com- first pair of them given in the Encyclopædia. The semon alum.

There is likewise a pure sulphate of alumine, very altringent, very difficult of crystallization, in the form of brilliant pearl-coloured plates without confiftence, cable numbers, with the properties from which they re-

even has the advantage over the latter falt, because if and which cannot be rendered insoluble by the addition Alum of a new quantity of its base. 'This last falt may with Amicable the greatest propriety be called the fulphate of alumine.

7. It follows from the comparative analysis, and the knowledge acquired respecting the different states of the combination of alumine with the fulphuric acid united at the same time with other bases, that we must distinguish seven states in this combination, and that it is neceffary to express them according to the rules of the methodical nomenclature. Here follow the feries, the nature, and the names of these seven sulphates of alu-

1. Sulphate of alumine, or the artificial combination of fulphuric acid and alumine. This falt is aftringent; it crystallizes in laminæ or flexible leaves, foluble in water. It has never been described nor named by chemists. 2. Acid sulphate of alumine is the foregoing falt, with excess of acid, from which it differs by reddening blue vegetable colours. It is eafily made by diffolving that falt in the fulphuric acid, but it is not eafy to convert this into the neutral sulphate of alumine but by boiling it a long time with its earth. This falt, like the first, has not been described. 3. Saturated fulphate of alumine and of pot-ash is the alum of the chemists saturated with its earth. It is pulverulent, infipid, infoluble, not crystallizable, and is easily converted into true alum by the addition of sulphuric acid. 4. The acid fulphate of alumine and of pot-ash greatly resembles common alum, and is easily prepared chemically; but M. Vauquelin found no alum but that of La Tolfa which is exactly of the same nature with it. 5. The acid fulphate of alumine and of ammoniac has all the properties of alum, and may be used for the same purposes; but though it is easily made in the laboratories, our author never found it pure in commerce. 6. The acid sulphate of alumine, pot-ash, and ammoniac. It is remarkable enough, fays M. Vauquelin, that this should be the nature of the alum most frequently made in the arts, and that to express its convbination fo many words should be necessary. This, however, may be avoided, by referving the name of alum to this substance, which will be sufficient to distinguish it perfectly. 7. The acidulous sulphate of alumine and of pot-ash, our author says, he is less acquainted with than with the preceding feries. The name by which he characterizes it was suggested to him, and he thinks it proper, because by adding to the solution a fmall quantity of pot-ash more than is necessary to obtain octahedral crystals, it manifestly passes to the cubic form.

From these deductions, the physician, the chemist, and the manufacturer, with whom the uses of alum are greatly multiplied, will hereafter possels a knowledge of the substance they employ, and may appreciate its cffects on the animal economy, and other bodies to which it is so frequently applied. See Annales de Chimie, xxii. 258, and Nicholfon's Journal, Vol. I. p. 318, &c.

ALUMINE, one of the simple earths. See CHE-

MISTRY in this Supplement.

AMICABI.E NUMBERS have been defined, and the cond pair of amicable numbers are 17296 and 18416; and the third pair are 9363584 and 9437056.

Dr Hutton informs us, that these three pairs of ami-

Amicable, ceive their name, were found out by F. Schooten, as Amster- appears from Sect. ix. of his Exercitationes Mathematice. To find the first pair, he puts 4x and 4yz, or a2x and a^2yz for the two numbers where a=2; then making each of these equal to the sum of the aliquot parts of the other, gives two equations, from which are found the values of x and z, and confequently affuming a proper value for y, the two amicable numbers themselves

In like manner for the other pairs of fuch numbers: in which he finds it necessary to assume 16x and 16yz, or a4x and a4yz for the fecond pair, and 128x and 128yz

or a7 a and a7 yz for the third pair.

Schooten then gives this practical rule, from Defcartes, for finding amicable numbers, viz. affume the number 2, or some power of the number 2, such that if unity or 1 be subtracted from each of these three following quantities, viz. from 3 times the affumed number. also from 6 times the assumed number, and from 18 times the square of the assumed number, the three remainders may be all prime numbers; then the last prime number being multiplied by double the affumed number, the product will be one of the amicable numbers fought, and the fum of its aliquot parts will be the other. That is, if a be put = the number 2, and n fome integer number, fuch that 3an-1, and 6an-1, and $18a^{2n}-1$ be all three prime numbers; then is $18a^{2n}-1$ ×2an one of the amicable numbers; and the fum of its aliquot parts is the other.

AMSTERDAM and ST PAUL, are two islands in the South Sea, lying in the fame degree of longitude, and generally confounded with each other. The Dutch navigators have given the name of Amsterdam to the northern, and of St Paul to the fouthern island, and Captain Cook conforms to that appellation. Most other English navigators, and particularly Messrs Cox and Mortimer, with Sir George Staunton, reverse the names, calling the fonthern island Amsterdam, and the other St Paul. At this fouthern island the Lion man of war stopped on her voyage to China with Lord Macartney, the late ambassador to the court of Pekin, which gave an opportunity to the men of science in the train of the ambassador to examine the island with more skill and attention than probably it had ever been exa-

mined before.

Dr Gillan, who was appointed physician to the embaffy, as well for his knowledge of chemistry as for his medical skill, is confident that the island of Amsterdam is the product of subterraneous fire, as it bears in every part of it evident marks of volcanic eruption. "On the west and south-west sides (says he) there are sour finall cones regularly formed, with craters in their centres, in which the lava and other volcanic fubstances have every appearance of recent formation. The heat continues still fo great, and such a quantity of elastic vapours issues through numberless crevices, that there can be no doubt of their having been very lately in a state of eruption. In a thermometer placed upon the furface, the quickfilver role constantly to 180 degrees, and when funk a little into the ashes, it advanced to 212 degrees. It certainly would have rifen still higher; but the scale being graduated only to the point of boiling water, and the length of the tube proportioned to that extent, the thermometer was immediately withdrawn, lest the increasing expansion of the quickfilver should

SUPPL. VOL. I. Part I.

burst the glase. The ground was felt tremulous under Amster. the feet; a stone thrown violently upon it returned a hollow found; and the heat was fo intense for a considerable distance around, that the foot could not be kept for a quarter of a minute in the same position without being fcorched. But the great crater on the eastern fide, now full of water, is by far the largest here, or perhaps elsewhere, and is of an aftonishing fize, confiderably exceeding in diameter those of Etna or Vesuvius. The quantity of matter to be thrown up, which required fo wide an orifice for its passage, and the force with which fuch matter was impelled, in order to overcome the refistance of the fuperincumbent earth and fea, must have been indeed prodigious.

"This vast crater, according to the usual method of computing the antiquity of volcanoes, must have been formed at a very remote period. The lava all around its fides is much decomposed, and has mouldered into dust, which lies on the furface in many parts to a confiderable depth. The decomposition has supplied a rich foil for the long grafs growing on the fides of the crater, and has even spread over most parts of the island. The fibrous roots of the grafs, extending in all directions through the decomposed lava and volcanic ashes, and mixed in a decaying flate with the vegetable mould, produced from the annual putrefaction of the leaves and stalks, have formed a layer of foil several seet deep all over the island. But as it has nothing except its own weight to compress it together, it is of a light fponcy texture, with very little cohesion, and in many places furrowed and interfected by the fummer rains, and the torrents occasioned by the melting of the snow which lies upon it in the winter, from three to four feet thick, in all those places where the subterraneous heat is not great enough to prevent its accumulation. In some parts these furrows and cavities are deeper than the level of the common channel; hence they serve the purpole of small natural reservoirs. The water flows into them from all the neighbouring ground; and as their fides are shaded, and almost covered over by the leaves of the long grass, growing from their edges in opposite directions, the rays of the sun are excluded, and very little is loft by evaporation. These reservoirs, however, are very fmall, and but few in number; the largest could not contain more than three or four hogsheads of water; and there is none else to be found, except in the springs on the sides of the large crater.

"The foil everywhere being light and fpongy, and full of holes, formed in it by fea-birds for nelts, is very troublesome to walk upon; the foot breaks through the furface, and finks deep at every ftep; a circumstance which renders the journey acrofs the island uncommonly fatiguing, although it be fearcely three miles from the edge of the great crater to the opposite west side. There is one place near the centre of the island, extending about 200 yards in length, and fomewhat less in breadth, where particular caution is necessary in walking over it. From this spot a hot tresh spring is supposed to derive its fource, finding its way through the interflices of the lava to the great crater, and burfling out a little above the water covering its bottom. heat in this upper fpot is too great to admit of vegetation. The furface is covered with a kind of mud or paste formed from the ashes, moistened by steam conflantly rifing from below. When the mud is removed,

Amster- the vapour iffues forth with violence, and in some parts This mud is fo hot, that a gentleman who copioufly. inadvertently stepped into it, had his foot severely scalded by it. The same causes which have prevented vegetation on this spot, have had the same effect on the four cones recently thrown up. Their furfaces are covered with ashes only; nor is there the least appearance even of moss on the furrounding lava, for the production of which there does not appear to have elapfed a fufficient length of time fince the cones were formed: but this is not the case with the lava of the great primary crater; for in those parts of it where the edges are more perpendicular, and where confequently the mouldering decomposed earth, having no baffs to support it, flides down the fides of the rock, pretty long moss was generally found growing upon it. All the fprings or refervoirs of hot water, except one only, were brackish. One spring derives its source from the high ground and ridges of the crater. The water in it, instead of boiling upwards through the stones and mud, as in the other fprings, flows downward with a confiderable velocity, in a small collected stream. Its temperature has been found not to exceed 112 degrees. The hand could be eafily kept in it for a confiderable time. It is a pretty ftrong chalybeate. The fides of the rock whence it issues, and of the cavity into which it falls, are incrusted with ochre deposited from it.

"When the great crater is viewed from the high ground, it appears to have been originally a perfect circle, but to have been encroached upon by the fea on the castern side, where the flood tide strikes violently. The rocks of lava which formed the edge of the crater on that fide have fallen down. The depth of the water in the crater is about 170 feet, rendering the whole height of the crater, from the bottom to its upper ridge, nearly if not quite 900 feet. The lofty rocks forming this ridge are the highest parts of the island, which feems to have been originally produced by the melted lava flowing down on all fides from hence. Thus there is a gradual slope from the edges of the crater to the fea; and the lava, though very irregular, and lying in mixed ruin and confusion immediately around the crater, assumes a more uniform appearance at some distance, layer resting regularly upon layer, with a gradual declivity the whole way down to the fea. This disposition of the layers is particularly observable in the west side, where they happen to terminate in an abrupt precipice. The eruptions that took place at different periods appear here distinctly marked by the different layers that are found with regular divisions between them; the glaffy lava being undermost, the compact next, the cel-Iular lava next above, over it the volcanic ashes and lighter fubstances, and a layer of vegetable mould covering the whole.'

The island appears indeed in such a state of volcanic inflammation, that from the ships decks at night were observed, upon the heights of the island, several fires isfuing out of the crevices of the earth, more confiderable, but in other respects resembling somewhat the nightly flames at Pietra Mala, in the mountains between Florence and Bologna, or those near Bradley in Lancashire, occasioned by some of the coal-pits having taken fire. In the day nothing more than smoke could be per-

The length of the island from north to fouth is up-

wards of four miles, its breadth from east to west about Amstertwo miles and a half, and its circumference eleven miles, comprehending a furface of about eight square miles, or 5120 acres, almost the whole of which is covered with a fertile foil. The island is inaccessible except on the east fide, where the great crater forms a harbour, the entrance to which is deepening annually, and might by the aid of art be made fit for the passage of large ships. The tides run in and out at the rate of three miles an hour, and rife perpendicularly eight or nine feet on the full and change of the moon; a northerly wind making the highest tide. The water is eight or ten fathoms deep close to the edge of the crater; and in the bason formed by the crater itself, the variation of the compass was found to be nineteen degrees and fifty minutes weltward of the north pole.

On the island, which has no native inhabitants, were found three Frenchmen and two natives of England, who at the end of the American war had emigrated to Boston. 'The whole five had come last from the Isle of France in the Indian Ocean, and had been left on the island of Amsterdam, about five months before the arrival of the Lion, for the purpole of procuring a cargo of 25,000 feal-skins for the Canton market, which, as they had already procured 8000, they hoped to complete in about ten months more. The veffel which brought them from the Isle of France was gone to Nootka Sound, with a view of bringing a quantity of fea-otter skins to China; and afterwards of calling for the cargo of feal skins at this place, to be carried to China likewife; proceeding thus alternately to Nootka and Amsterdam island as long as the owners should find

their account in it.

The feals, whose skins are thus an article of commerce, are found here in greater numbers in the fummer than in the winter, when they generally keep in deep water, and under the weeds, which shelter them from the inclemency of the weather. In the fummer months they come ashore, sometimes in droves of 800 or 1000 at a time, out of which about 100 are destroyed, that number being as many as five men can skin and peg down to dry in the course of a day. Little of the oil which these animals might furnish is collected, for want of casks to put it in; part of the best is boiled, and serves those people instead of butter. The seal of Amsterdam is the phoca urfina of Linnæus. The female weighs usually from 70 to 120 pounds, and is from three to five feet in length, but the male is confiderably larger. In general they are not shy: sometimes they plunge into the water instantly upon any one's approach, but at other times remain steadily on the rocks, bark, and rear themselves up in a menacing posture; but the blow of a stick upon the nose seemed fufficient to dispatch them. As the skins alone were the objects wanted, the carcafes were left on the ground to putrify at leifure, strewed in such numbers as to render it difficult to avoid treading on them in walking along. The people thus employed were remarkable for the fqualor and filth of their perfons, clothes, and dwelling; yet none of them feemed desirous of leaving the place before the business they came upon should be completed. One of them, an Englishman, who had been a confiderable time upon the island on a former adventure, gave but an unfavourable account of the weather during the winter months, which are always boisterous, Anaclastic.

Amster- boisterous, with hail and snow; but in summer he ac-

knowledged it to be very fine.

The tea supplies this island with great varieties of excellent fish, particularly a kind of cod, which was equally relished whether fresh or salted. Cray sish were in such abundance on the bar across the entrance into the crater, that at low water they might be taken with the hand; and at the anchorage of the ships, when baskets, in which were proper baits, were let down into the fea, they were in a few minutes drawn up filled with cray fish. This circumstance is the more extraordinary, that in the same place were found abundance of sharks and dog fish of uncommon fize, which are known to be fo voracious and fuch enemies to all other fish. The bason of the crater abounds with tench, bream, and perch; and the person who with a hook and line has caught any of their fish in the cold water of the bason, may with a flight motion of his hand let them drop into the adjoining hot spring already mentioned, in which they will be boiled and rendered fit for eating in the space of fifteen minutes. This was often practiled by the gentlemen of the embassy, and furnished them at once with a fingular amusement and a highly relished

Of all the birds which frequent this island, so extraordinary in its origin, formation, and appearance, not one is common to the fame degree of latitude in the northern hemisphere. Of the larger kind were several species of the albatros; on examining one of which, distinguished by the name of exulans, it was found, that instead of having only the rudiments of a tongue, as naturalists generally suppose, it had one equalling half the length of the bill. Another large bird is likewise common here, called the great black petrel, or procellaria equinoctialis of Linnæus. It is the determined enemy of the albatrofe, as well as of the blue petrel of Amfterdam, or procellaria forsteri. This blue petrel, which is about the fize of a pigeon, constitutes the principal food of the feal-catchers on the island. During the day-time they hide themselves in the ground, in order to escape, if possible, their destroyer the black petrel. At night they come abroad, and thence are termed night birds by the people at Amsterdam; but being fond of slocking to any light, they fall into another fnare laid for them by the feal-catchers, who kindle torches to attract them, and then kill them in multitudes. The prettiest of the feathered tribe, inhabiting or visiting Amsterdam, is the filver bird, or sterna birundo, about the fize of a large swallow or swift, with a forked or swallow tail. The bill and legs are of a bright crimfon colour, the belly white, and the back and wings of a bluish ash colour. This bird fubfifts chiefly on small fish, which it picks

up as they are swimming over the surface of the water.

This singular island lies in 38° 42' S. Lat. and in 76° 54' E. Long. from Greenwich. St Paul's, or the island lying in fight and to the northward, differed in appearance materially from Amsterdam. It presented no very high land, or any rifing in a conic form; and feemed to be overspread with shrubs or trees of a middling fize. It was faid to abound with fresh water, but to have no good anchorage near it, nor any place of easy landing .- Sir George Staunton's Account of an

Embassy to the Emperor of China.

ANACLASTIC CURVES, a name given by M. de Mairan to certain apparent curves formed at the bottom

of a vessel full of water, to an eye placed in the air; or Anaphora the vault of the heavens, seen by refraction through the Anderson.

ANAPHORA, in aftrology, the fecond house, or that part of the heavens which is 30 degrees from the horoscope. The term anaphora is also sometimes applied promiscuously to some of the succeeding houses, as the 5th, the 8th, and the 11th. In this lense anaphora is the same as epanaphora, and stands opposed to cataphora.

ÁNASTROUS signs, in aftronomy, a name given to the duodecatemoria, or the twelve portions of the ecliptic, which the figns possessed anciently, but have fince

deferted by the precession of the equinox.

ANCHOR OF A SHIP, is an instrument which, as it is commonly made, has been sufficiently described in the Encyclopædia. An improvement, however, has been proposed on its construction by Mr James Stuard of the parish of St Anne, Middlesex, who obtained a patent for his invention, dated Feb. 9. 1796.

The whole of this invention confifts in making the anchor with one fluke or arm instead of two, and contriving to load that fluke or arm in fuch a manner as to make it always fall the right way. With this view Mr Stuard would have the shank of the anchor made very fhort, that it may cant the more when suspended by the cable; and he would have the arm and it made of bars in one length, that there may be no shoot or joining in the whole instrument. The bend of the shank and arm he would have rounded, and not angular as in the common anchor; and on this bend he would have a small shackle, or two plates with a small bolt between them, for the buoy-rope to be made fast to. Instead of wood. he proposes for the stock of the anchor a bar of wrought iron, loaded or covered at the ends with knobs of caft iron; and he would have the palm of the fluke or arm either to be composed entirely of cast iron, or to be a cast iron shell filled with lead. This weight of the palm, the shortness of the shank, and the structure of the stock, will no doubt make the anchor fall the right way; which, having no upper fluke, will never be tripped by the cable taking hold of it on the ship's swinging, nor will it prove fo dangerous as the common anchor to fuch vessels as may happen to ground by it.

ANDERSON (Alexander), an eminent mathematician, was born at Aberdeen towards the end of the 16th century. Where he was educated, or under what masters, we have not learned; probably he studied the belles lettres and philosophy in the university of his native city, and, as was the practice in that age of all who could afford it, went afterwards abroad for the cultivation of other branches of science. But wherever he may have studied, his progress in science must have been rapid; for, early in the 17th century, we find him professor of mathematics in the university of Paris, where he published several ingenious works; and among others, 1. Supplementum Apollonii Redivivi; sive analy-sis problematis hactenus desiderati ad Apollonii Pergai doctrinam σερε νευσεων, a Marino Ghetaldo Patritio Ragusino hujufque, non ita pridem restitutam. In qua exhibetur mechanice aqualitatum tertii gradus sive folidarum, in quibus magnitudo omnino data, equatur homogenee sub altero tantum coefficiente ignoto. Huic subnexa est variorum problematum practice, Paris, 1612, in 4to .- 2. Αιτιολογια: Pro Zetetico Apolloniani problematis a se jam pridem edito in

Supplementa

Anderson, supplemento Apollonii Redivivi. Ad clarissimum et orna-Anhings. tissimum virum Marinum Ghetaldum Patritium Ragusinum. In qua ad ea que obiter mihi perstrinxit Ghetaldus respondetur, et analytices clarius detegitur. Paris, 1615, in 4to .- 3. Francisci Vieta Fontenacensis de Æquationum Recognitione et Emendatione Tractatus duo, with a dedication, preface, and appendix, by himself. Paris, 1615, in 4to .- 4. Vieta's Angulares Sectiones; to which he added demonstrations of his own. Our professor was cousin german to Mr David Anderson of Finshaugh, a gentleman who also possessed a singular turn for mathematical knowledge. This mathematical genius was hereditary in the family of the Andersons; and from them it seems to have been transmitted to their descendants of the name of Gregory, who have for so many generations been eminent in Scotland as professors either of mathematics, or, more lately, of the theory and practice of physic. The daughter of the David Anderson just mentioned, was the mother of the celebrated James Gregory, inventor of the reflecting telescope; and observing in her fon, while yet a child, a strong propensity to mathematical studies, she instructed him in the elements of that science herself. From the same lady descended the late Dr Reid of Glasgow, who was not less eminent for his knowledge of mathematics than for his writings as a metaphyfician.

The precise dates of Alexander Anderson's birth and death, we have not learned either from Dempster, Mackenzie, or Dr Hutton, who feems to have used every endeavour to procure information; nor are fuch of his relations as we have had an opportunity of confulting, fo well acquainted with his private history as

we expected to find them.

ANHINGA, in ornithology, a species of the pelicanus; confifts of four known varieties, two peculiar to America, one to Senegal, and the fourth to the region about the Cape of Good Hope. This last is thus described by Le Vaillant in his New Travels into the Interior Parts of Africa.

"The denomination of Slange-Hals- Voogel, given to it by the Hottentots, characterises the anhinga in a very fimple and accurate manner. Buffon, who was ftruck with the conformation peculiar to birds of this kind, has delineated them by a fimilar expression. Plate III. 6 The anhinga (fays he) exhibits a reptile grafted on the body of a bird.' Indeed there is no person who, upon feeing the head and neck only of an anhinga, while the rest of the body is hid among the foliage of the tree on which it is perched, would not take it for one of those serpents accustomed to climb and reside in trees; and the mistake is so much the easier, as all its tortuous motions fingularly favour the illusion. In whatever fituation the anhinga may be feen, whether perched on a tree, swimming in the water, or flying in the air, the most apparent and remarkable part of its body is fure to be its long and flender neck, which is continually agitated by an ofcillatory motion, unless in its flight, when it becomes immoveable and extended, and forms with its tail a perfectly straight and horizon-

> "The true place which nature feems to have affigned to the anhingas, in the numerous class of the palmipedes, is exactly between the cormorant and the grebe. They partake indeed equally of both these genera of birds, having the straight slender bill and the long neck

of the latter; while they approach the former by the Anhinga conformity of their feet, the four toes of which are joined by a fingle membrane. They partake also of Antimeter. the cormorant by their flight; having like it the wings larger and fitter for the purpose than those of the grebe, which are flort and weak. The tail of the anhinga is extremely long; a characteristic very fingular and remarkable in a water fowl, and which ought, it would feem, to render them totally distinct from diving birds, which in general have little or no tail. By this trait they approach still nearer to the cormorants; for tho' the tails of the latter are shorter, the tails of both have a great refemblance to each other, fince their quills are equally strong, elastic, and proper to form a rudder when these fowls swim through the water in pursuit of sish, which constitute their principal nourishment. When the anhinga feizes a fish, he swallows it entire if it be fmall enough, and if too large he carries it off to a rock or the stump of a tree, and fixing it under one of his feet, tears it to pieces with his bill.

"Though water is the favourite element of this bird, it builds its nest and rears its young on rocks and trees; but it takes great care to place them in such a manner. that it can precipitate them into a river as foon as they are able to fwim, or the fafety of the little family may

require it."

I he male anhinga differs from the female, which is fmaller, in having the whole under part of the body, from the breast to the root of the tail, of a beautiful black, while the latter has the same parts of a yellow isabella colour. It has also, on each side of its neck, a white stripe, which extends from the eye to the middle of its length, and interfects a reddish ground. A very fingular characteristic, common to all the anhingas, is that of having the feathers of the tail deeply striated, and as it were ribbed. It is a very fagacious bird, efpecially when surprised swimming; for its head is the only part which it expoles above the water; and if the sportiman once miss that part, the anhinga plunges out of fight entirely, and never more shows itself but at very great distances, and then no longer at a time than is abfolutely necessary for breathing.

ANTECEDENTAL CALCULUS. See CALCULUS

in this Supplement.

ANTES, in architecture, small pilastres placed at the corners of buildings.

ANTICS, in architecture, figures of men and ani

mals placed as ornaments to buildings.

ANTICUM, in architecture, a porch; also that part of a temple which lies between the body of the temple and the portico, and is therefore called the outer

ANTIMETER, or Reflecting Sector, an instrument invented by Mr William Garrard, for the purpose of measuring angles, particularly small ones, with a greater degree of accuracy than can be done by Had-

ley's quadrant or by the fextant.

The frame of this instrument is fimilar to that of Hadley's quadrant, having two radii, a limb, and braces; but with this difference, that the further radius is produced upwards of four inches beyond the centre of motion of the index; and the great speculum, or what is called the index-glass in Hadley's quadrant, being placed there, is called the upper centre. In this instrument there is no provision for the back observation.

Antimeter. I'he horizon-glass is like that in Hadley's quadrant; there are two fight vanes, to fuit two different fituations of the large speculum or object glass: these vanes are adapted to receive a small telescope. On the centre of the index, where the index-glass of Hadley's quadrant is fixed, is a brass or bell-metal semicircle, two inches in diameter, and one-eighth of an inch thick: this semicircle is screwed fast to the index, in such a manner that the axis of the index is a tangent to it. On the upper centre are two circular brass plates, which revolve concentrically, either together or feparately. The under plate has a lever, or part perpendicular to the plane of the instrument, projecting downwards, a little beyond the lower centre: this lever is acted upon by the semicircular plate at the lower centre, to which it is always kept close by a spring on the other side. In the upper of the above mentioned circular plates are two circular perforations or flits, through one of which a ferew takes into the head of the instrument, and thro' the other a screw takes into the lower moveable plate. The large speculum is fastened to the upper plate; and by the above mentioned screws the position of this glass may be altered. A circular plate is fixed to the lower centre by three pillars: in its centre is a nut to admit a ferew, by which the plate carrying the large speculum may be fastened here occasionally.

The scale on the limb is divided into 45 equal parts or degrees, and not into half degrees as is the case in Hadley's quadrant, by reason of the double reflection. These divisions are numbered in a retrograde order; zero being at the extremity of the further radius. Although the limb contains 45 degrees, yet the greatest angle which can be measured, the large speculum remaining fixed to the circular plate, is to 18' 21".8; the distance between the two centres being four inches, and the radius of the femicircle one inch. Agreeable to these dimensions, the inventor has given a table exhibiting the value of each primary division on the limb; he hath also given a more ample table, adapted to a distance between the centres of three times the radius of the femicircle, which he fays hath been found the most convenient in practice. If an angle greater than 10° 18' is wanted, it may be measured by the method of anticipation, as the inventor calls it, which is as follows: Let the screw which fasteus the two circular plates on the upper centre be made fast, and loosen the screw which fastens the upper circular plate to the instrument: Now adjust the glasses by the usual method; bring forward the index to any given division on the limb, and make it fast; also sasten the screw which was before loose, and loosen the other screw; then bring the index to zero, and proceed as before.

The inventor gives the following directions for ad-

justing and using the instrument.

The first thing to be attended to is, to set the horizon-glass perpendicular to the plane of the instrument, which is performed as follows: Hold the instrument with its plane perpendicular to the horizon, and look over backwards into the glass and beyond it. If the limb of the instrument appears in a right line with its reflection, the glass is upright; but if it does not appear so, loosen or tighten the little screw on the foot of the glass until it be adjusted: Then with the instrument, as in taking an altitude, look through the fight vane or telescope at some distant object, with the index fixed

in any intended fituation; the two fcrews at the upper Antiparalcentre being loofe, turn the glass about till the fame object appears nearly in the same part of the horizonglass: Next hold it in a horizontal position, and adjust the object-glass or large speculum with the screws which are behind and before, on the foot of it, till the object and its reflection are feen in the fame horizontal line. Lattly, with the instrument upright, turn the tangentferew belonging to the horizon-glass at the back of the instrument, until there be a perfect coincidence of the object and its reflection that way, and the adjustments are complete.

ANTIPARALLELS, in geometry, are those lines which make equal angles with two other lines, but contrary ways; that is, calling the former pair the first and fecond lines, and the latter pair the third and fourth lines, if the angle made by the first and third lines be equal to the angle made by the fecond and fourth, and contrariwise the angle made by the first and fourth equal to the angle made by the fecond and third; then each pair of lines are antiparallels with respect to each other, viz. the first and second, and the third and fourth. So, if AB and AC be any two lines, and FC and FE be Plate II. two others, cutting them for two others, cutting them fo,

that the angle B is equal to the angle E, and the angle C is equal to the angle D; then BC and DE are antiparallels with respect to AB and AC; also these latter are antiparallels with regard to the two former. It is a property of these lines, that each pair cuts the other into proportional fegments, taking them alternately,

viz. AB : AC : : AE : AD : : DB : EC, and FE: FC:: FB: FD:: DE: BC.

APERTURE, in optics, has been defined in the Encyclopædia, but no rule was given there for finding a just aperture. As much depends upon this circumstance, our optical readers will be pleased with the following practical rule given by Dr Hutton in his Mathematical Dictionary. " Apply feveral circles of dark paper, of various fizes, upon the face of the glass, from the breadth of a straw to such as leave only a small hole in the glass; and with each of thefe, separately, view fome diffant object, as the moon, stars, &c. then that aperture is to be chosen through which they appear the most distinctly.

" Huygens first found the use of apertures to conduce much to the perfection of telescopes; and he found by experience (Diopt. prop. 56.), that the best aperture for an object-glass, for example of 30 feet, is to be determined by this proportion, as 30 to 3, so is the square root of 30 times the distance of the focus of any lens to its proper aperture: and that the focal diltances of the eye glasses are proportioned to the apertures. And M. Auzout fays he found, by experience, that the apertures of telescopes ought to be nearly in the subduplicate ratio of their lengths. It has also been found by experience, that object-glasses will admit of greater apertures, if the tubes be blacked within fide, and their passage furnished with wooden rings.

"It is to be noted, that the gleater or less aperture of an object-glass, does not increase or diminish the vifible area of the object; all that is effected by this is the admittance of more or fewer rays, and confequently the more or less bright the appearance of the object. But the largenels of the aperture or focal diftance causes

Arch.

Apocatas the irregularity of its refractions. Hence, in viewing Venus through a telescope, a much less aperture is to be used than for the moon, or Jupiter, or Saturn, because her light is so bright and glaring. And this circumstance somewhat invalidates and disturbs Azout's proportion, as is shown by Dr Hook, Phil. Trans. N° 4."

APOCATASTASIS, or, as it should be written, AFORATASTASIS, is a Greek word employed in the language of astronomers, to denote the period of a planet, or the time it takes to return to that point of the

zodiac whence it fet out.

APOTOME, is a term employed by Euclid to denote the difference between two lines or quantities which are only commensurable in power. Such is the difference between 1 and 12, or the difference between the fide of a square and its diagonal. The doctrine of apotomes in lines, as delivered by this ancient mathematician in the tenth book of his Elements, is a very cutrious ubject, and has always been admired by fuch as understood it. The first algebraical writers in Europe, fuch as Lucas de Burgo, Cardan, Tartalea, Stifelius, &c. employed a confiderable portion of their works on an algebraical exposition of that which led them to the doctrine of furd quantities.

APPARENT conjunction of the planets, is when a right line, supposed to be drawn through their centres, pages through the eye of the spectator, and not through the centre of the earth And, in general, the apparent conjunction of any objects, is when they appear or are

placed in the same right line with the eye.

APPARENT Diameter of a planet or other heavenly body, is not the real length of the diameter of that body, but the angle which it fubtends at the eye, or under which it appears.

APPARENT Distance, is that which we judge an object to be from us, when seen afar off; and which is almost

always very different from the true distance.

APPARENT Figure, is the figure or shape under which an object appears when viewed at a distance; and is often very different from the true figure. Thus a straight line, viewed at a distance, may appear but as a point; a surface. as a line; and a solid, as a surface.

APPARENT Motion, is either that motion which we perceive in a distant body that moves, the eye at the fame time being either in motion or at rest; or that motion which an object at rest seems to have, while the

eye itielf only is in motion.

APPARENT Place of a Planet, &c. in aftronomy, is that point in the furface of the sphere of the world where the centre of the luminary appears from the furface of the earth.

APPARITION, in astronomy, denotes a star's or other luminary's becoming visible, which before was hid. So, the heliacal rifing, is rather an apparition than a pro-

Arch de-

ARCH, in building, is an artful disposition and adjustment of several stones or bricks, generally in a bowlike form, by which their weight produces a mutual pressure and abutment; so that they not only support each other, and perform the office of an entire lintel, but may be extended to any width, and made to carry the most enormous weights.

In those mild climates which seem to have been the first inhabited parts of this globe, mankind stood more

in need of shade from the fun than of shelter from the Arch. inclemency of the weather. A very small addition to the shade of the woods served them for a dwelling. History of Sticks laid across from tree to tree, and covered with architecbrushwood and leaves, formed the first houses in those ture condelightful regions. As population and the arts impro-nected with ved, these huts were gradually refined into commodious arches. dwellings. The materials were the same, but more artfully put together. At last agriculture led the inhabitants out of the woods into the open country. The connection between the inhabitant and the foil became now more constant and more interesting. The wish to preserve this connection was natural, and fixed establishments followed of course. Durable buildings were more defirable than those temporary and perishable cottages - stone was substituted for timber.

But as these improved habitations were gradual refinements on the primitive hut, traces of its construction remained, even when the choice of more durable materials made it in some measure inconvenient. Thus it happened, that while a plain building, intended for accommodation only, confifted of walls, pierced with the necessary doors and windows, an ornamented building had, fuperadded to these effentials, columns, with the whole apparatus of entablature, borrowed from the wooden building, of which they had been effential parts, gradually rendered more suitable to the purposes of ac-

commodation and elegance.

This view of ornamental architecture will go far to Origin of account for some of the more general differences of na. Greek artional ftyle which may be observed in different parts of the world. The Greeks borrowed many of their arts from their Afiatic neighbours, who had cultivated them long before. It is highly probable that architecture travelled from Persia into Greece. In the ruins of Shushan, Persepolis, or Tchilminar, are to be seen the first models of every thing that distinguishes the Grecian architectures. There is no doubt, we suppose, among the learned, as to the great priority of these monuments to any thing that remains in Greece; especially if we take into account the tombs on the mountains, which have every appearance of greater antiquity than the remains of Persepolis. In those tombs we see the whole ordonnance of column and entablature, just as they began to deviate from their first and necessary forms in the wooden buildings. We have the architrave, frize, and corniche; the far-projecting mutules of the Tufcan and Doric orders; the modillions no less diffinet; the rudiments of the Ionic capital; the Corinthian capital in perfection, pointing out the very origin of this ornament, viz. a number of long graceful leaves tied round the head of the column with a fillet (a custom which we know to have been common in their temples and banqueting rooms). Where the distance between the columns is great, fo that each had to support a weight too great for one tree, we see the columns clustered or fluted, &c. In short, we see every thing of the Grecian architecture but the floped roof or pediment; a thing not wanted in a country where it hardly ever rains.

The ancient Egyptian architecture seems to be a re- Egyptian, finement on the hut built of clay, or unburnt bricks mixed with straw - every thing is massive, clumsy, and timid-fmall intercolumnations, and hardly any projections.

The Arabian architecture seems a refinement on the Arabian, tent. A mosque is like a little camp, consisting of a and.

Plate I.

Origin of

the arch.

Grecian.

number of little bell tents, fluck close together round a fays that they are arched; a circumflance which we Arch. great one. A caravanseray is a court surrounded by a row of fuch tents, each having its own dome. The Greek church of St Sophia at Constantinople has imitated this in some degree; and the copies from it, which have been multiplied in Russia as the facred form for a Christian church, have adhered to the original model of clustered tents in the strictest manner. We are sometimes disposed to think that the painted glass (a fashion brought from the East) was an imitation of the painted hangings of the Arabs.

The Chinese architecture is an evident imitation of a Chinese architecture. wooden building. Sir Geo. Staunton fays, that the fingular form of their roofs is a professed imitation of the cover of a square tent.

In the stone-buildings of the Greeks, the roofs were imitations of the wooden ones; hence the lintels, flying

corniches, ceilings in compartments, &c.

The pediment of the Greeks feems to have fuggefted the greatest improvement in the art of building. In erecting their small houses, they could hardly fail to obferve occasionally, that when two rafters were laid together from the opposite walls, they would, by leaning on each other, give mutual support, as in fig. 1. Nor is it unlikely that such a situation of stones as is reprefented in fig. 2. would not unfrequently occur by accident to masons. This could hardly fill of exciting a little attention and reflection. It was a pretty obvious reflection, that the stones A and C, by overhanging, leaned against the intermediate stone B, and gave it fome support, and that B cannot get-down without thrusting aside A and C, or the piers which support them. This was an approach to the theory of an arch; and if this be combined with the observation of fig. 1. we get the disposition represented in fig. 3. having a perpendicular joint in the middle, and the principle of the arch is completed. Observe that this is quite different from the principle of the arrangement in fig. 2. In that figure the stones act as wedges, and one cannot get down without thrusting the rest aside; the same principle obtains in fig. 4. confifting of five arch stones; but in fig. 3. the stones B and C support each other by their mutual pressure (independent of their own weight), arising from the tendency of each lateral pair to fall outwards from the pier. This is the principle of the arch, and would support the key-stone of fig. 4. although each of its joints were perpendicular, by reason of the great friction arising from the horizontal thrust exerted by the adjoining stones.

This was a most important discovery in the art of building; for now a building of any width may be

roofed with stone.

We are disposed to give the Greeks the merit of this discovery; for we observe arches in the most ancient buildings of Greece, fuch as the temple of the fun at Athens, and of Apollo at Didymos; not indeed as roofs to any apartment, nor as parts of the ornamental defign, but concealed in the walls, covering drains or other necessary openings; and we have not found any real arches in any monuments of ancient Persia or Egypt. Sir John Chardin speaks of numerous and extenfive subterranean passages at Tchelminar, built of the most exquisite masonry, the joints so exact, and the stones so beautifully dressed, that they look like one continued piece of polished marble: but he nowhere

think he would not have omitted-no arched door or window is to be seen. Indeed one of the tombs is faid to be arch-roofed, but it is all of one folid rock. No trace of an arch is to be feen in the ruins of ancient Egypt; even a wide room is covered with a fingle block of stone. In the pyramids, indeed, there are two galleries, whose roofs confift of many pieces: but their configuation puts it beyond doubt that the builder did not know what an arch was: for it is covered in the manner represented in fig. 5. where every projecting piece is more than balanced behind, fo that the whole aukward mass could have stood on two pillars. The Greeks therefore feem entitled to the honour of the invention. The arched dome, however, feems to have arifen in Etruria, and originated in all probability from the employment of the augurs, whose bufiness it was to observe the flight of birds. Their stations for this purpose were templa, so called a templando, "on the summits of hills." To shelter such a person from the weather, and at the same time allow him a full prospect of the country around him, no building was fo proper as a dome fet on columns; which accordingly is the figure of a temple in the most ancient monuments of that country. We do not recollect a building of this kind in Greece except that called the Lanthern of Demosthenes. which is of very late date, whereas they abounded in Italy. In the later monuments and coins of Italy or of Rome, we commonly find the Etruscan dome and the Grecian temple combined; and the famous pantheon was of this form, even in its most ancient state.

It does not appear that the arch was confidered as a part of the ornamental architecture of the Greeks during the time of their independency. It is even doubtful whether it was employed in roofing their temples. In none of the ancient buildings where the roof is gone, can there be feen any rubbish of the vault, or mark of the spring of the arch. It is not unfrequent, however, it was used after the Roman conquests, and may be seen in Athens, at first only Delos, Palmyra, Balbek, and other places. It is very in bridges frequent in the magnificent buildings of Rome; fuch ducts. as the Colifeum, the baths of Dioclesian, and the triumphal arches, where its form is evidently made the object of attention. But its chief employment was in bridges and aqueducts; and it is in those works that its immense utility is the most conspicuous: For by this happy contrivance a canal or a road may be carried across any stream, where it would be almost impossible to erect piers fufficiently near to each other for carrying lintels. Arches have been executed 130 feet wide, and their execution demonstrates that they may be made

four times as wide.

As fuch stupendous arches are the greatest perform- Difficulty ances of the malonic art, fo they are the most difficult of construcand delicate. When we reflect on the immense quanting it. tity of materials thus suspended in the air, and compare this with the small cohesion which the sirmest cement can give to a building, we shall be convinced that it is not by the force of the cement that they are kept together: they stand fast only in consequence of the proper balance of all their parts. Therefore, in order to erect them with a well-founded confidence of their durability, this balance should be well understood and judiciously employed. We doubt not but that this was understood in some degree by the engineers of antiqui-

Arch. Skill and ny Gacs.

ty. But they have left us none of their knowledge. They must have had a great deal of mechanical knowledge before they could erect the magnificent and beautiful buildings whose ruins still enchant the world; but of the Dio- they kept it among themselves. We know that the Dionyfiacs of Ionia were a great corporation of architects and engineers, who undertook, and even monopolized, the building of temples, stadiums, and theatres, precifely as the fraternity of masons in the middle ages monopolized the building of cathedrals and conventual churches. Indeed the Dionyfiacs refembled the mystical fraternity now called free majons in many important particulars. They allowed no ftrangers to interfere in their employment; they recognifed each other by figns and tokens; they professed certain mysterious doctrines, under the tuition and tutelage of Bacchus, to whom they built a magnificent temple at Teos, where they celebrated his mysteries as solemn festivals; and they called all other men profane, because not admitted to these mysteries. But their chief mysteries and most important fecrets feem to be their mechanical and mathematical sciences, or all that academical knowledge which forms the regular education of a civil engineer. We know that the temples of the gods and the theatres required an immense apparatus of machinery for the celebration of some of their mysteries; and that the Dionyfiacs contracted for those jobs, even at far distant places, where they had not the privilege of building the edifice which was to contain them. This is the most likely way of explaining the very small quantity of mechanical knowledge that is to be met with in the writings of the ancients. Even Vitruvius does not appear to have been of the fraternity, and speaks of the Greek architects in terms of respect next to veneration. The Collegium Murariorum, or incorporation of masons at Rome, does not feem to have shared the secrets of the Dionysiacs. The art of building arches has been most assiduously

12 The art of cultivated by the affociated builders of the middle ages building arches unages

by the

Romans.

of the Christian church, both Saracens and Christians, the middle and they feem to have indulged in it with fondness: they multiplied and combined arches without end, placing them in every possible situation. Having studied this branch of the art of building with fo much attention, they were able to erect the

most magnificent buildings with materials which a Greek or Roman architect could have made little or no use of. Better than There is infinitely more scientific skill displayed in a Gothic cathedral, than in all the buildings of Greece Greeks and and Rome. Indeed these last exhibit very little knowledge of the mutual balance of arches, and are full of gross blunders in this respect; nor could they have refifted the shock of time so long, had they not been almost folid masses of stone, with no more cavity than was indifpenfably necessary.

Anthemius and Isidorus, whom the Emperor Justi-Defects of the church nian had selected as the most eminent architects of of St Sophia Greece for building the celebrated church of St Sophia at Constan at Constantinople, seem to have known very little of he would outdo the magnificence of the Roman pan-

feen the magnificent vaultings of the temple of Mars the Avenger, and the temple of Peace at Rome, the thrusts of which are withstood by two masses of solid well, which join the fide walls of the temple at right angles, and extend sidewise to a great distance. It was evident that the walls of the temple could not yield to the preffure of the vaulting without pushing these immense buttresses along their foundations. He therefore placed four buttresses to aid his piers. They are almost folid masses of stone, extending at least 90 feet from the piers to the north and to the fouth, forming as it were the fide walls of the cross. They effectually secured them from the thrusts of the two great arches of the nave which support the dome; but there was no such provision against the push of the great north and south arches. Anthemius trufted for this to the half dome, which covered the femicircular east end of the church. and occupied the whole eaftern arch of the great dome. But when the dome was finished, and had flood a few months, it pushed the two eastern piers with their buttreffes from the perpendicular, making them lean to the eastward, and the dome and half dome fell in. Isidorus, who fucceeded to the charge on the death of Anthemius, strengthened the piers on the east side, by filling up some hollows, and again raised the dome. But things gave way before it was closed; and while they were building in one part it was falling in in another. The pillars and walls of the eastern semicircular end were much shattered by this time. Isidorus seeing that they could give no resistance to the push which was for evidently directed that way, erected fome clumfy buttreffes on the east wall of the square which surrounded the whole Greek crofs, and was roofed in with it, forming a fort of cloifler round the whole. These buttresses, spanning over this cloister, leaned against the piers of the dome, and thus opposed the thrusts of the great north and fouth arches. The dome was now turned for the third time, and many contrivances were adopted for making it extremely light. It was made offenfively flat; and, except the ribs, it was roofed with pumice stone; but, notwithstanding these precautions, the arches fettled fo as to alarm the architects, and they made all fure by filling up the whole from top to bottom with arcades in three stories. The lowest arcade was very lofty, supported by four noble marble columns, and thus preserved, in some measure, the church in the form of a Greek cross. The story above formed a gallery for the women, and had fix columns in front, fo that they did not bear fair on those below. The third story was a dead wall filling up the arch, and pierced with three rows of small ill-shaped windows. In this unworkmanlike shape it has stood till now, and is the oldest church in the world; but it is an ugly mishapen mass, more refembling an overgrown potter's kiln, furrounded with furnaces pieced and patched, than a magnificent temple. We have been thus particular in our account of it, because this history of the building shows that the ancient architects had acquired no distinct notions of the action of arches. Almost any mason of our time would know, this matter. Anthemius had boafted to Justinian, that that as the fouth arch would push the pier to the eastward, while the east arch pushed it to the southward, theon, for he would hang a greater dome than it aloft the buttress which was to withstand these thrusts must in the air. Accordingly he attempted to raife it on not be placed on the fouth fide of the pier, but on the in the air. Accordingly he attempted to raile it on not be piaced on the four fine pier, but on the the heads of four piers, diftant from each other about fouth-east fide, or that there must be an eastern as well such as are never found. 115 feet, and about the same height. He had probably as a southern buttress. No such blunders are to be seen in a Gothic

Arch.

arches

Explained,

in a Gothic cathedral. Some of them appear, to a care- plane. If the perpendicular through the centre of graless spectator, to be very massive and clumfy; but when judiciously examined, they will be found very bold and light, being pierced in every direction by arcades, and the walls are divided into cells like a honeycomb, for that they are very stiff, while they are very light. About the middle, or rather towards the end, of last

century, when the Newtonian mathematics opened the road to true mechanical science, the construction of arches engroffed the attention of the first mathematicians. Dr Hooke's The first hint of a principle that we have met with is principle of Dr Hooke's affertion, that the figure into which a chain or rope, perfectly flexible, will arrange itself when sufpended from two hooks, is, when inverted, the proper form for an arch composed of stones of uniform weight. This he affirmed on the same principle which is made use of in the Encyclopædia Britannica in the article Roor, § 25. viz. that the figure which a flexible feftoon of heavy bodies assumes, when suspended from two points, is, when inverted, the proper form for an arch of the same bodies, touching each other in the same points; because the forces with which they mutually press on each other in this last case, are equal and opposite to the forces with which they pull at each other in the case of suspension.

This principle is strictly just, and may be extended to every case which can be proposed. We recollect seeing it proposed, in very general terms, in the St James's Chronicle in 1759, when plans were forming for Blackfriar's Bridge in London; and fince it is perhaps equal, in practical utility, to the most elaborate investigations of the mathematicians, our readers will not be displeased with a more particular account of it in this place.

Let ABC (fig. 6.) be a parcel of magnets of any fize and shape, and let us suppose that they adhere with great force by any points of contact. They will compose fuch a flexible sestion as we have been speaking of, if suspended from the points A and C. If this figure be inverted, preferving the same points of contact, they will remain in equilibrio. It will indeed be that kind of equilibrium which will admit of no diffurbance, and which may be called a tottering equilibrium. If the form be altered in the smallest degree, by varying the points of contact (which indeed are points in the figure of equilibration), the magnets will no more recover their former position than a needle, which we had made to stand on its point, will regain its perpendicular position after it has been disturbed.

But if we suppose planes de, fg, hi, &c. drawn, that the points of mutual contact a, b, c, each bifecting the angle formed by the lines that unite the adjoining contacls (fg, for example, hifecting the angle formed by ab, bc), and if we suppose that the pieces are changed for others of the same weights, but having flat sides, which meet in the planes de, fg, bi, &c. it is evident that we shall have an arch of equilibration, and that the arch will have some stability, or will bear a little change of form without tumbling down: for it is plain that the equilibrium of the original festoon obtained only in the points a, b, c, of contact, where the pressures were perpendicular to the touching furfaces; therefore if the curve a, b, c, still passes through the touching surfaces perpendicularly, the conditions that are required for equilibrium still obtain. The case is quite similar to that of the stability of a body resting on a horizontal SUPPL. VOL. I. Part I.

vity falls within the base of the body, it will not only fland, but will require some force to push it over. In the original festoon, if a small weight be added in any part, it will change the form of the curve of equilibration a little, by changing the points of mutual contact. This new curve will gradually separate from the former curve as it recedes from A or C. In like manner, when the festoon is set up as an arch, if a small weight be laid on any part of it, it will bring the whole to the ground, because the shifting of the points of contact will be just the contrary to what it should be to suit the new curve of equilibration. But if the same weight be laid on the same part of the arch now constructed with flat joints, it will be fustained, if the new curve of equilibration still passes through the touching surfaces.

These conclusions, which are very obviously deducible from the principle of the festoon, shew us, without any further discussion, that the longer the joints are, the greater will be the flability of the arch, or that it will require a greater force to break it down. Therefore it is of the greatest importance to have the arch stones as long as economy will permit; and this was the great use of the ribs and other apparent ornaments in the Gothic architecture. The great projections of those ribs augmented their stiffness, and enabled them to support the unadorned copartments of the roof, composed of very small stones, seldom above fix inches thick. Many old bridges are still remaining, which are strengthened in the same way by ribs.

Having thus explained, in a very familiar manner, the stability of an arch, we proceed to give the same popular account of the general application of the prin-

Suppose it to be required to ascertain the form of an Aniaparch which shall have the span AB (fig. 7.), and the plied. height F8, and which shall have a road-way of the dimensions CDE above it. Let the figure ACDEB be inverted, fo as to form a figure AcdeB. Let a chain of uniform thickness be suspended from the points A and B, and let it be of fuch a length that its lower point will hang at, or rather a little below, f, correfponding to F. Divide AB into a number of equal parts, in the points 1, 2, 3, &c. and draw vertical lines, cutting the chain in the corresponding points 1, 2, 3, &c. Now take pieces of another chain, and hang them on at the points 1, 2, 3, &c. of the chain A f B. This will alter the form of the curve. Cut or trim thefe pieces of chain, till their lower ends all coincide with the inverted road-way cde. The greater lengths that are hung on in the vicinity of A and B will pull down these points of the chain, and cause the middle point f (which is less loaded) to rise a little, and will bring it near to its proper height.

It is plain that this process will produce an arch of perfect equilibration; but fome farther confiderations are necessary for making it exactly suit our purpose. It is an arch of equilibration for a bridge, that is fo loaded that the weight of the arch flones is to the weight of the matter with which the haunches and crown are loaded, as the weight of the chain A f B is to the fum of the weights of all the little bits of chain very nearly. But this proportion is not known beforehand; we must therefore proceed in the following manner: Adapt to the curve produced in this way a thick-

ne's of the arch stones as great as are thought sufficient to enfure stability; then compute the weight of the arch flones, and the weight of the gravel or rubbish with which the haunches are to be filled up to the road-way. If the proportion of these two weights be the same with the proportion of the weights of chain, we may rest satisfied with the curve now found; but if different, we can eafily calculate how much must be added equally to, or taken from, each appended bit of chain, in order to make the two proportions equal. Having altered the appended pieces accordingly, we shall get a new curve, which may perhaps require a very-small trimming of the bits of chain to make them fit the road-way. This curve will be infinitely near to the curve wanted.

We have practifed this method for an arch of 60 feet span and 21 feet height, the arch stones of which were only two feet nine inches long. It was to be loaded with gravel and shivers. We made a previous computation, on the supposition that the arch was to be nearly elliptical. 'The diffance between the points 1, 2, 3, &c. were adjusted, so as to determine the proportion of the weights of chain agreeable to the suppofition. The curve differed confiderably from an ellipse, making a confiderable angle with the verticals at the fpring of the arch. The real proportion of the weights of chain, when all was trimmed fo as to fuit the roadway, was confiderably different from what was expected. It was adjusted. The adjustment made very little change in the curve. It would not have changed it two inches in any part of the real arch. When the process was completed, we constructed the curve mathematically. It did not differ fenfibly from this mechanical construction. This was very agreeable information; for it showed us that the first curve, formed by about two hours labour, on a supposition considerably different from the truth, would have been fufficiently exact for the purpose, being in no place three inches from the accurate curve, and therefore far within the joints of the intended arch stones. Therefore this procels, which any intelligent mason, though ignorant of mathematical science, may go through with little trouble, will give a very proper form for an arch subject to any

The chief defect of the curve found in this way is a want of elegance, because it does not spring at right angles to the horizontal line; but this is the cafe with all curves cording to. of equilibration, as we shall see by and by. It is not material: for, in the very neighbourhood of the piers, we may give it any form we please, because the masonry is solid in that place; nay, we apprehend that a deviation from the curve of equilibration is proper. The construction of that curve supposes that the pressure on every part of the arch is vertical; but gravel, earth, and rubbish, exert fomewhat of a hydrostatical pressure laterally in the act of fettling, and retain it afterwards. This will require fome more curvature at the haunches of an arch to balance it; but what this lateral pressure may be, cannot be deduced with confidence from any experiments that we have feen. We are inclined to think that if, instead of dividing the horizontal line AB in the points 1, 2, 3, &c. we divide the chain itself into equal parts, the curve will approach nearer to the pro-

> After this familiar statement of the general principle, it is now time to consider the theory founded on it

more in detail. This theory aims at fuch an adjustment of the position of the arch stones to the load on Pheory every part of the arch, that all shall remain in equili-founded on brio, although the joints be perfectly polished, and with this prinout any cement. The whole may be reduced to two ciple. problems. The first is to determine the vertical preffure or load on every point of a line of a given form, which will put that line in equilibrio. The fecond is to determine the form of a curve which shall be in equilibrio when loaded in its different points, according to any given law.

The whole theory is deducible from § 27. of the article Roor. The fundamental propolition in that fection states the proportions between the various pressures or thrusts which are exerted at the angles of an affemblage of beams or other pieces of folid heavy matter, freely moveable about those angles, as so many joints, but retaining their position by the equilibrium of those pressures. It is there demonstrated, "that the thrust at any angle, if estimated in a horizontal direction, is the fame throughout, and may be represented by any horizontal line BT, fig. 8. (Roofs, fig. 10 Pl. CCCCXL); and that if a vertical line QIS be drawn through T, the thrust exerted at any angle D by the piece CD, in its own direction, will then be represented by BR, drawn parallel to CD; and in like manner, that the thrust in the direction ED is represented by BS, &c.; and, laftly, that the vertical thrufts or loads, at each angle B, C, D, by which all these other pressures are excited, are represented by the portions QC, CR, RS, of the vertical intercepted by those lines; that is, all these pressures are to the uniform horizontal thrust as the lines which represent them are to BT. The horizontal thrust, therefore, is a very proper unit, with which we may compare all the others. Its magnitude is easily deduced from the same proposition; for QS is the fum of all the vertical pressures of the angles, and therefore represents the weight of the whole assemblage. Therefore as QS is to BT, fo is the weight of the whole to the horizontal thrust.

To accommodate this theory to the construction of Accommoa curvelineal arch vault, let us first suppose the vault to dated to the be polygonal, composed of the cords of the elementary tion of an arches. Let AVE (fig. 9.) be a curvelineal arch, of arch vault, which V is the vertex, and VX the vertical axis, which we shall consider as the axis or abscissa of the curve, while any horizontal line, such as HK, is an ordinate to the curve. About any point C of the curve as a centre describe a circle BLD, cutting the curve in B and D. Draw the equal cords CB, CD. Draw also the horizontal line CF, cutting the circle in F. Defcribe a circle BCDQ paffing through B, C, D. Its centre O will let in a line COQ, which bifects the angle BCD, and Cd, which touches this circle in C, will bisect the angle b C d, formed by the equal cords BC, CD. Draw CLP perpendicular to cb, and DP perpendicular to CD, meeting CL in P. Through L. draw the tangent GLM, meeting CD in G, and the vertical line CM in M. Draw the tangent Fa, cutting the cords BC, CD, in b and d, and the tangent to the circle BCDQ in c. Lastly, draw dN parallel to b c.

From what is demonstrated in § 27. of the article Roof, it appears, that if BC, CD be two pieces of an equilibrated heavy polygon, and if CF represent the horizontal thrust in every angle of the polygon, Cd and

The chief defect of ciple.

Cb will feverally represent the thrusts exerted by the pieces DC, BC, and that bd, or CN, will represent the weight lying on the angle BCD, by which those thrusts are balanced.

As the reader may not have the article Roof at hand, this equilibrium may be recalled to his remembrance in the following manner: Produce $d \, C$ to o, fo that $C \, o$ may be equal to $C \, d$. Draw $b \, n$ to the vertical parallel to dB, and join no. It is evident that $b n \circ C$ is a parallelogram, and that n C (= b d) = CN. Now the thrust or support of the piece BC is exerted in the direction C b, while that of DC is exerted in the direction Co. These two thrusts are equivalent to the thrust in the diagonal Cn; and it is with this compound thrust that the load or vertical pressure CN is in immediate equilibrium.

Because bCL, NCF, are right angles, and FCL is common to both, the angles b CF and MCL are equal. Therefore the right angled triangles b CF and MCL are similar. And since CF is equal to CI., cb is equal to CM. It is evident that the triangles GCM and dCN are fimilar. Therefore CG:Cd=CM:CN,

= Cb:CN. Therefore we have $CN = \frac{Cb \times Cd}{CG}$. But

because CDP and CLG are right angles, and therefore equal, and the angle GCP is common to the two triangles GCL, PCD, and CD is equal to CL, we have

CG equal to CP. Therefore $CN = \frac{Cb \times Cd}{CP}$. Also,

fince CDP is a right angle, DP meets the diameter in O, the opposite point of the circumference, and the angle DQC is equal to DCd, or DCb (because bCd is bifected by the targent), that is, to PCQ (because the right angles lCP, cDO are equal, and cDP is common). Therefore PQ is equal to PC; and if PO be drawn perpendicular to CQ, it will bifect it, and O is the centre of the circle BCDQB.

Now let the points B and D continually approach to (by diminishing the radius of the small circle), and ultimately coincide with it. It is evident that the circle BCDQ is ultimately the equicurve circle, and that PC ultimately coincides with OC, the radius of curvature. Also $Cb \times Cd$ becomes ultimately Cc^2 . Therefore CN, the vertical load on any point of a curve

of equilibration, is $=\frac{C}{Rad. Curv.}$

It is farther evident, that CF is to Cc as radius to the fecant of the elevation o' the tangent above the horizon. Therefore we have the load on any point of Sec.2 Elev. the curve always proportional to Rad. Curv.

This load on every elementary arch of the wall is commonly a quantity of folid matter incumbent on that element of the curve, and preffing it vertically; and it may be conceived as made up of a number of heavy lines standing vertically on it. Thus, if the element Ee of the curve were lying horizontally, a little parallelogram REer, standing perpendicularly on it, would represent its load. But as this element E e has a sloping position, it is plain that, in order to have the same quantity of heavy matter pressing it vertically, the height of the parallelogram must be increased till it meets in ep, the line R . drawn parallel to the tangent EG. It is evident that the angle RE p is equal to the

angle AEG. Therefore we have ER: E = Rad.: Arch.

If therefore the arch is kept in equilibrio by the vertical pressure of a wall, we must have the height of the

wall above any point proportional to Rad. of Curv.

COR. I. If OS be drawn perpendicular to the verti-Corollaries, cal CS, CS will be half the vertical cord of the equicurve circle. The angle OCS is equal to c CF, that is. to the angle of elevation. Therefore 1: Sec. Elev. = CS: CO, and the fecant of elevation may be expreffed by $\frac{CO}{CS}$, and its cube by $\frac{CO^3}{CS^3}$. Therefore the height of wall is proportional to $\frac{CO^3}{CS^3 \times CO}$, or to $\frac{CO^2}{CS^3}$, or $\frac{CO^2}{CS^2 \times CS}$, or to $\frac{Sec.^2 \text{ of Elev}}{Vert. \text{ Cord of Curv.}}$

COR. II. If we make the arch VC = z, the abscissa VH = N, the ordinate HC = y, the radius of culi CO = r, and the $\frac{1}{2}$ vertical cord CS = s, the height of wall pref-

fing on any point is proportional to $\frac{z^3}{y^3}$; or to $\frac{z^2}{y^2}$, or $\frac{z^2}{y^2s}$. Therefore, when the equation of the curve

is given, and the height of wall on any one point of it is also given, we can determine it for any other point: for the equation of the curve will always give us the relation of z, x, and y, and the value of r or s. This may be illustrated by an example or two. For this purpose it will generally be most convenient to assume the height above the vertex V for the unit of computation. The thickness of the arch at the crown is commonly determined by other circumstances. At the vertex the tangent to the arch is horizontal, and therefore the cube of the fecaut is unity or 1. Call the height of wall, at the crown, H, and let the radius of curvature in that point be R, and its half cord R (it being then coincident with the radius), and the height on any other

point *b*. We have $\frac{1}{R}: \frac{z^3}{y^3r} = H: b$, and $b = H \times \frac{z^3}{y^3} \times \frac{R}{r}$. The other formula gives $b = H \times \frac{z^2}{y^2} \times \frac{R}{s}$.

Examp. 1. Suppose the arch to be a segment of a Illustrated circle, as in fig. 10. where AE is the diameter, and O by examthe centre In this arch the curvature is the fame Ples.

throughout, or $\frac{R}{r} = 1$. Therefore $b = H \times \frac{z^3}{y^3}$, or

= H × Cube Sec. Elev.

This gives a very fimple calculus. To the logarithm of H add thrice the logarithm of the secant of elevation. The fum is the logarithm of h.

It gives also a very simple construction. Draw the vertical CS, cutting the horizontal diameter in S. Draw ST, cutting the radius OC perpendicularly in T. Draw the horizontal line Tz, cutting the vertical in z. Join zo. Make Cu = Vv, and draw $u \times parallel$ to zo. Cc must be made = Cx. The demonstration is evi-

It is very eafy to see that if CV is an arch of 60°, and V v is 72th of VC, the points v and c will be on a level; for the fecant of CV is twice CO, and therefore Cc is 8 times V v, which is 7th of VH. The

And demonstrased.

The dotted line vgcf is drawn according to this calculus or confiruction. It falls confiderably below the horizontal line in the neighbourhood of c; and then, passing very obliquely through c, it rises rapidly to an unmeasurable height, because the vertical line through A is its assymptote. This must evidently be the case with every curve which springs at right angles with a horizontal line.

It is plain that if v V be greater, all the other ordinates of the curve vgcf, resting on the circumference AVE, will be greater in the same proportion, and the curve will cut the horizontal line drawn through v in fome point nearer to v than c is. Hence it appears that a circular arch cannot be put in equilibrio by building on it up to a horizontal line, whatever be its Ipan, or whatever be the thickness at the crown. We have feen that when this thickness is only tath of the radius, an arch of 120 degrees will be too much loaded at the flanks. This thickness is much too small for a bridge, being only 1 th of the span CM, whereas it should have been almost double of this, to bear the inequalities of weight that may occasionally be on ic. When the crown is made still thinner, the outline is still more depressed before it rifes again. There is therefore a certain span, with a corresponding thickness at the crown, which will deviate least of all from a horizontal line. This is an arch of about 54 degrees, the thickness at the crown being about one-fourth of the span, which is extravagantly great. It appears in general therefore, that the circle is not a curve fuited to the purposes of a bridge or an arcade, which requires an outline nearly horizontal.

Examp. 2. Let the curve be a parabola AVE (fig. 11.), of which V is the vertex, and DG the directrix. Draw the diameters DCF, GVN, the tangents CK, VP, and the ordinates VF and CN. It is well known that GV is to DC as VP² to CK², or as CN² to CK². Also 2 GV is the radius of the osculating circle at V, and 2 DC is one-half of the vertical cord of the osculating circle at C. Therefore CN²: CK² (or $\dot{y}^2:\dot{z}^2$)=R:s, and $s=\frac{\dot{z}^2}{\dot{y}^2}$ R. But Cc, or $b=H\times\frac{\dot{z}^2}{\dot{y}^2}$ R. Therefore $b=H\times\frac{\dot{z}^2}{\dot{y}^2}$ R. Therefore $b=H\times\frac{\dot{z}^2}{\dot{y}^2}$ R. Therefore

It follows from this investigation, that the back or extrados of a parabolic arch of equilibration must be parallel to the arch or soffit itself; or that the thickness of the arch, estimated in a vertical direction, must be equal throughout; or that the extrados is the same parabola with the sossit or intrados.

We have felected these two examples merely for the fimplicity and perspicuity of the solutions, which have been effected by means of elementary geometry only, instead of employing the analytical value of the radius

of the ofculatory circle viz. $\frac{x^3}{y \times - xy}$, which would have involved us at least in the elements of second

have involved us at least in the elements of second fluxions. We have also preferred simplicity to elegance in the investigation, because we wish to instruct the practical engineer, who may not be a proficient in the higher mathematics.

The converse of the problem, namely, to find the form of the arch when the figure of the back of it is given, is the most usual question of the two, at least in To find the cases which are most important and most difficult. Of form of an these perhaps bridges are the chief. Here the necessity arch when of a road-way, of easy and regular ascent, consines us the figure to an outline nearly horizontal, to which the curve of its back the arch must be adapted. This is the most difficult problem of the two; and we doubt whether it can be solved without employing infinite approximating series instead of accurate values.

Let a v e (fig. 12.) be the intended outline or extrados of the arch AVE, and let $v \in \mathbb{Q}$ be the common axis of both curves. From c and C, the corresponding points, draw the ordinates c h, CH. Let the thickness $v \in \mathbb{Q}$ at the top be a, the abscissa $v \in \mathbb{Q}$ be $v \in \mathbb{Q}$, and VH $v \in \mathbb{Q}$, and let the equal ordinates $v \in \mathbb{Q}$, CH be $v \in \mathbb{Q}$, and the arch VC be $v \in \mathbb{Q}$.

If we now substitute the true value of u (which is given, because the extrados is supposed to be of a known form), expressed in terms of y, the resulting equation will contain nothing but x and y, with their first and second fluxions, and known quantities. From this equation the relation of x and y must be found by such methods as seem best adapted to the equation of the extrados.

Fortunately the process is more simple and easy in the most common and useful case than we should expect from this general rule. We mean the case where the extrados is a straight line, especially when this is horizontal. In this case u is equal to o.

Example. To find the form of the balanced arch AVE (fig. 13.), having the horizontal line cv for its Plate IL extrados.

Keeping the fame notation, we have u = o, and therefore $a + x = \frac{C}{y} \times \text{fluxion of } \frac{x}{y}$.

Affume $y = \frac{x}{v}$; then $\frac{x}{y} = v$, and $\frac{C}{y} \times \text{fluxion of } \frac{x}{y}$. $= \frac{Cvv}{y}$, that is $a + x = \frac{Cvv}{x}$. Therefore ax + xx. = Cvv; and by taking the fluents, we have $2ax + x^2$. $= Cv^2$; and $v = \sqrt{\frac{2ax + x^2}{C}}$. Confequently, $y = \frac{\sqrt{Cx}}{\sqrt{2ax \times x^2}}$ (being $= \frac{x}{v}$). Taking the fluent of this, we have $y = \sqrt{C \times L}$ ($2ax + 2x^2$).

 $+ 2 \sqrt{2 a x + x^2}$. But at the vertex, where x = 0, we have $y = \sqrt{C \times L(2a)}$. The corrected fluent is therefore $y = \sqrt{C \times L^{a+x+\sqrt{2ax+x^2}}}$

It only remains to find the constant quantity C. This we readily obtain by felecting some point of the extrados where the values of x and y are given by par-ticular circumstances of the case. Thus, when the span 2 s and height h of the arch are given, we have $s = \sqrt{C \times L \left(\frac{a+b+\sqrt{2ab+b^2}}{a}\right)}$, and confequently $\sqrt{C} = \frac{s}{L\left(\frac{a+b+\sqrt{2ab+b^2}}{a}\right)}$. Therefore the general value of $y = s \times \frac{L\left(\frac{a+x+\sqrt{2ax+x^2}}{a}\right)}{L\left(\frac{a+b+\sqrt{2ab+b^2}}{a}\right)};$ $= \frac{s}{L^{\frac{a+b+\sqrt{2ab+b^2}}{}}} \times L^{\frac{a+s+\sqrt{2as+s^2}}{}}.$

As an example of the use of this formula, we subjoin a table calculated by Dr Hutton of Woolwich for an arch, the span of which is 100 feet and the height 40, which are nearly the dimensions of the middle arch of Blackfriars Bridge in London.

y	20	y	. 20	1 9	×
0 2 4 6 8	6,000 6,035 6,144 6,324 6,580 6,914	21 22 23 24 25 26	10,381 10,858 11,368 11,911 12,489 13,106	36 37 38 39 40 41	21,774 22,948 24,190 25,505 26,894 28,364

Defects of sian curve.

The figure for this proposition is exactly drawn acthe Catina- cording to these dimensions, that the reader may judge of it as an object of fight. It is by no means deficient in gracefulness, and is abundantly roomy for the passage of craft; fo that no objection can be offered against its being adapted on account of its mechanical excellency.

> The reader will perhaps be surprifed that we have made no mention of the celebrated Catenarean curve, which is commonly said to be the best form for an arch; but a little reflection will convince him, that although it is the only form for an arch confifting of stones of equal weight, and touching each other only in fingle points, it cannot fuit an arch which must be filled up in the haunches, in order to form a road way. He will be more surprised to hear, after this, that there is a certain thickness at the crown, which will put the Catenarea in equilibrio, even with a horizontal road-way;

but this thickness is fo great as to make it unfit for a Arch. bridge, being such that the pressure at the vertex is equal to the horizontal thrust. This would have been about 37 feet in the middle arch of Blackfriars Bridge. The only fituation therefore in which the Catenarean form would be proper, is an arcade carrying a height of dead wall; but in this fituation it would be very ungraceful. Without troubling the reader with the inveiligation, it is sufficient to inform him that in a Catenarean arch of equilibration the abscissa VH is to the absciffa v h in the constant ratio of the horizontal thrust to its excess above the proffure on the vertex.

This much will serve, we hope, to give the reader a Inutility of clear notion of this celebrated theory of the equilibrium the comof arches, one of the most delicate and important appli-mon theory cations of mathematical science. Volumes have been bration. written on the subject, and it still occupies the attention of mechanicians. But we beg leave to fay, with great deference to the eminent perfons who have profecuted this theory, that their speculations have been of little fervice, and are little attended to by the practitioner. Nay, we may add, that Sir Christopher Wren, perhaps the most accomplished architect that Europe has feen, feems to have thought it of little value: for, among the fragments which have been preserved of his studies, there are to be seen some imperfect dissertations on this very subject, in which he takes no notice of this theory, and confiders the balance of arches in quite another way. These are collected by the author of the account of Sir Christopher Wren's family. This man's great fagacity, and his great experience in building, and, ftill more his experience in the repairs of old and crazy fabrics, had shown him many things very inconsistent with this theory, which appears so specious and safe. The general facts which occur in the failure of old arches are highly inflructive, and deferve the most careful attention of the engineer; for it is in this state that their defects, and the process of nature in their destruction, are most distinctly seen. We venture to affirm, that a very great majority of these facts are irreconcileable to the theory. The way in which circular arches commonly fail, is by the finking of the crown and the rifug of the flanks. It will be found by calculation, that in most of the cases it ought to have been just the contrary. But the clearest proof is, that arches very rarely fail where their load differs most remarkably from that which this theory allows. Semicircular arches have stood the power of ages, as may be seen in the bridges of ancient Rome, and in the numerous arcades which the ancient inhabitants have erected. Now all arches which spring perpendicularly from the horizontal line, require, by this theory, a load of infinite height; and, even to a confiderable distance from the springing of the arch, the load necessary for the theoretical equilibrium is many times greater than what is ever laid on those parts; yet a failure in the immediate neighbourhood of the spring of an arch is a most rare phenomenon, if it ever was observed. Here is a most remarkable deviation from the theory; for, as is already observed, the load is frequently not the fourth part of what the theory requires.

Many other facts might be adduced which show great deviations from the legitimate results from the theory. We hope to be excused, therefore, by the mathematicians for doubting of the justness of this theory. We

do not think it erroneous, but defective, leaving out circumstances which we apprehend to be of great im-Its defects, portance; and we imagine that the defects of the theory have arisen from the very anxiety of the mechanicians to make it perfect. The arch stones are supposed to be perfectly smooth or polished, and not to be connected by any cement, and therefore to sustain each other merely by the equilibrium of their vertical preffure. The theory enfures this equilibrium, and this only, leaving unnoticed any other causes of mutual action.

> The authors who have written on the subject say expressly, that an arch which thus sustains itself must be ftronger than another which would not; because when, in imagination, we suppose both to acquire connection by cement, the first preserves the influence of this connection unimpaired; whereas in the other, part of the cohefion is wasted in counteracting the tendency of some parts to break off from the rest by their want of equilibrium. This is a very specious argument, and would be just, if the forces which are mutually exerted between the parts of the arch in its fettled Itate were merely vertical preffures, or, where different, were inconfiderable in comparison with those which are really attended to in the construction.

But this is by no means the case. The forms which the uses for which arches are erected oblige us to adopt, and the loads laid on the different points of the arch, frequently deviate confiderably from what are necessary for the equilibrium of vertical pressures. The varying load on a bridge, when a great waggon paffes along it, fometimes bears a very fensible proportion to the weight of that point of the arch on which it refts. It is even very doubtful whether the preffures which are occafioned by the weight of the stuff employed for filling up the flanks really act in a vertical direction, and in the proportion which is supposed We are pretty certain that this is not the case with sand, gravel, fat mould, and many fubstances in very general use for this purpose. When this is the case, the pressures sustained by the different parts of the arch are often very inconfiftent with the theory-a part of the arch is overloaded, and tends to fall in, but is prevented by the cement. This part of the arch therefore acts on the remoter parts by the intervention of the parts between, employing those intermediate parts as a kind of levers to break the arch in a remote part, just as a lintel would be broken. We apprehend that a mathematician would be puzzled how to explain the stability of an arch cut out of a folid and uniform mass of rock. His theory confiders the mutual thrusts of the arch stones as in the direction of the tangents to the arch. Why fo? because he supposes that all his polished joints are perpendicular to those tangents. But in the present case he has no existing joints; and there seems to be nothing to direct his imagination in the affumption of joints, which, however, are absolutely necessary for employing his theory, because, without a supposition of this kind, there feems no conceiving any mutual abutment of the arch Ask a common, but intelligent, mason what notion he forms of such an arch? We apprehend that he will confider it as no arch, but as a lintel, which may be broken like a wooden lintel, and which refifts entirely by its cohefion. He will not readily conceive that, by cutting the under fide of a stone lintel into an arched form, and thus taking away more than half of

its substance, he has changed its nature of a lintel, or Arch. given it any additional strength. Nor would there be any change made in the way in which fuch a mals of stone would refist being broken down, if nothing were done but forming the under fide into an arch. If the lintel be so laid on the piers that it can be broken without its parts pushing the piers aside (which will be the cafe if it lies on the piers with horizontal joints), it will break like any other lintel; but if the joints are directed downwards, and converging to a point within the arch, the broken stone (suppose it broken at the crown by an overload in that part) cannot be pressed down without forcing the piers outwards. Now, in this mode of asting, the mind cannot trace any thing of the flatical equilibrium that we have proceeded on in the foregoing theory. The two parts of the broken lintel feem to push the piers aside in the same manner that two rafters push outwards the walls of a house, when their feet are not held together by a tye-beam. If the piers cannot be pushed aside (as when the arch abuts on two folid rocks), nothing can prefs down the crown which does not crush the stone.

This conclusion will be strictly true if the arch is of fuch a form that a straight line drawn from the crown to the pier lies wholly within the folid masonry. Thus if the vault confift of two straight stones, as in fig. 1. or if it confist of several stones, as in sig. 14. disposed in two straight lines, no weight laid on the crown can destroy it in any other way but by crushing it to

But when fraight lines cannot be drawn from the Whee it is overloaded part to the firm abutments through the fo. to be called lid mafonry, and when the cohesion of the parts is not alto the aid able to withstand the transverse strains, we must call the der. principles of equilibrium to our aid; and, in order to employ them with fafety, we must consider how they are modified by the excitement of the cohering forces.

The cohesion of the stones with each other by cement or otherwise, has, in almost every fituation, a bad effect. It enables an overload at the crown to break the arch near the haunches, causing those parts to rife, and then to spread outwards, just as a Mansarde or Kirb roof would do if the trus-beam which connects the heads of the lower rafters were fawn through. This can be prevented only by loading that part more than is requilite for equilibrium. It would be prudent to do this to a certain degree, because it is by this cohesion that the crown always becomes the weakest part of the

arch, and fuffers more by any occasional load.

We expect that it will be faid in answer to all this, that the cohesion given by the strongest cement that we can employ, nay the cohesion of the stone itself, is a mere nothing in comparison with the enormous thrusts that are in a state of continual exection in the different parts of an arch. This is very true; but there is another force which produces the same effect, and which increases nearly in the proportion that those thrusts increase, because it arises from them. This is the friction of the stones on each other. In dry freestone this friction confiderably exceeds one half of the mutual preffure. The reflecting reader will fee that this produces the same effect, in the case under consideration, that cohesion would do; for while the arch is in the act of failing, the mutual preffure of the arch stones is acting with full force, and thus produces a friction more than

adequate

adequate to all the effects we have been speaking Arch.

Process of the breaking of an

When these circumstances are considered, we imagine that it will appear that an arch, when exposed to a great overload on the crown (or indeed on any part), divides, of itself, into a number of parts, each of which contains as many arch stones as can be pierced (so to speak) by one straight line, and that it may then be confidered as nearly in the fame fituation with a polygonal arch of long stones butting on each other like so many beams in a Norman roof (fee Roof, no 49.), but without their braces and ties. It tends to break at all those angles; and it is not sufficiently resisted there, because the materials with which the flanks are filled up have fo little cohefion, that the angle feels no load except what is immediately above it; whereas it should be immediately loaded with all the weight which is diffused over the adjoining side of the polygon. This will be the cafe, even though the curvelineal arch be perfeely equilibrated. We recollect some circumstances in the failure of a confiderable arch, which may be worth mentioning. It had been built of an exceedingly foft and friable stone, and the arch stones were too short. About a fortnight before it fell, chips were observed to be dropping off from the joints of the architones about ten feet on each fide of the middle, and also from another place on one fide of the arch, about twenty feet from its middle. The masons in the neighbourhood prognosticated its speedy downfal, and faid that it would feparate in those places where the chips were breaking off. At length it fell; but it first split in the middle, and about 15 or 16 feet on each fide, and also at the very springing of the arch. Immediately before the fall a shivering or crackling noise was heard, and a great many chips dropped down from the middle between the two places from whence they had dropped a fortnight before. The joints opened above at those new places above two inches, and in the middle of the arch the joints opened below, and in about five minutes after this the whole came down. Even this movement was plainly diftinguishable into two parts. The crown funk a little, and the haunches rose very fensibly, and in this state it hung for about half a minute. arch stones of the crown were hanging by their upper corners. When these splintered off, the whole fell down.

We apprehend that the procedure of nature was somewhat in this manner. Straight lines can be drawn within the archstones from A (fig. 15.) to B and D, and from those points to C and E. Each of the portions ED, DA, AB, BC, refift as if they were of one flone, composing a polygonal vault EDABC. When this is overloaded at A, A can descend in no other way than by pushing the angles B and D outwards, causing the portions BC, DE, to turn round C and E. motion must raise the points B and D, and cause the arch stones to press on each other at their inner joints b and d. This produced the copious splintering at those joints immediately preceding the total downfal. The splintering which happened a fortnight before arose from this circumstance, that the lines AB and AD, along which the pressure of the overload was propagated, were tangents to the fosfit of the arch in the points F, H, and G. and therefore the strain lay all on those corners of the arch stones, and splintered a little from off them till the whole took a firmer bed. The subsequent phe- Arch. nomena are evident confequences of this diffribation and modification of preffure, and can hardly be explained in any other way; at least not on the theoretical principles already fet forth: for in this bridge the loads at B and D were very confiderably greater than what the equilibrium required; and we think that the first observed splintering at H, F, and G, was most instructive, showing that there was an extraordinary pressure at the inner joints in those places, which cannot be explained by the ufual theory

Not tatisfied with this fingle objervation, after this way of explaining it occurred to us, and not being able to find any fimilar fact on record, the writer of this article got some small models of arches executed in chalk, and subjected them to many trials, in hopes of collecting fome general laws of the internal workings of arches which finally produce their downfal. He had the pleasure of observing the above mentioned circumstances take place very regularly and uniformly, when he overloaded the models at A. The arch always broke at some place B considerably beyond another point F, where the first chipping had been observed. This is a method of trial that deferves the attention both of the

speculatist and the practitioner.

If these reflections are any thing like a just account of the procedure of nature in the failure of an arch, it is evident that the ingenious mathematical theory of equilibrated arches is of little value to the engineer. We ventured to fay as much already, and we refled a good deal on the authority of Sir Christopher Wren. He was a good mathematician, and delighted in the application of this science to the arts. He was a celebrated architect; and his reports on the various works committed to his charge, show that he was in the continual habit of making this application. Several specimens remain of his own methods of applying them. The roof of the theatre of Oxford, the roof of the cupola of St Paul's, and in particular the mould on which he turned the inner dome of that cathedral, are proofs of his having studied this theory most attentively. He flourished at the very time that it occupied the attention of the greatest mechanicians of Europe; but there is nothing to be found among his papers which shows that he had paid much regard to it. On the contrary, when he has occasion to deliver his opinion for the instruction of others, and to explain to the Dean and Chapter of Westminster his operations in repairing that collegiate church, this great architect confiders an arch just as a fentible and fagacious mason would do, and very much in the way that we have just now been treating it: (See Account of the Family of Wren, p. 356, &c.) Supported therefore by fuch authority, we would recommend this way of confidering an arch to the fludy of the mathematician; and we would defire the experienced mason to think of the most esticacious methods for refifting this tendency of arches to rife in the flanks. Unfortunately there feems to be no precise principle to point out the place where this tendency is most remark-

We are therefore highly pleafed with the ingenious contrivance of Mr Mylne, the architect of Blackfriars Bridge in London, by which he determines this point with precision, by making it impossible for the overloaded arch to spring in any other place. Having thus

confined the failure to a particular fpot, he with equal art opposes a resistance which he believes to be sufficient; and the present condition of that noble bridge, which does not in any place show the smallest change of shape, proves that he was not mistaken. Looking on this work as the first, or at least the second, specimen of masonic ingenuity that is to be seen in the world, we imagine that our readers will be pleafed with

a particular account of its most remarkable circumftances.

Construction of

mrch.

The span ka (fig. 16.) of the middle arch is 100 feet, and its height OV is 40, and the thickness KV Blackfriars of the crown is fix feet feven inches. Its form is nearly elliptical; the part AVZ being an arch of a circle whose centre is C, and radius 56 feet, and the two lateral portions A & B and Z a E being arches described with a radius of 35 feet nearly. The thickness of the pier at ab is 19 feet. The thickness of the arch increases from the crown V to Y, where it is eight or nine feet. All the arch stones have their joints directed to the centres of their curvature. The joints are all joggled, having a cubic foot of hard stone let half way into each. By this contrivance the joints cannot flide, nor can any weight laid on the crown ever break the arch in that part, if the piers do not yield; for a ftraight line from the middle of KV to the middle of the joint YI is contained within the folid mafonry, and does not even come near the inner joints of the arch Therefore the whole refists like one stone, and can be broken only by crushing it. The joint at Z is very nearly perpendicular to a line YF drawn to the outer edge of the foundation of the pier. By this it was intended to take off all tendency of the pressure on the joint dZ to overfet the pier; for if we suppose, according to the theory of equilibration, that this preffure is necessarily exerted perpendicularly to the joint, its direction passes through the fulcrum at F, round which it is thought that the pier must turn in the act of overfetting. This precaution was adopted, in order to make the arch quite independent of the adjoining arches; fo that although any of them should fall, this arch should

> Still farther to fecure the independence of the arch, the following construction was practifed to unite it into one mass, which should rife all together. All below the line a b is built of large blocks of Portland stone, dovetailed with found oak. Four places in each course are interrupted by equal blocks of a hard stone called Kentifh rag, funk half way in each courfe. These act as joggles, breaking the courses, and preventing them from

fliding laterally.

The portion a Y of the arch is joggled like the upper part. The interior part is filled up with large blocks of Kentish rag, forming a kind of coursed rubble-work, the courses tending to the centres of the arch. The under corner of each arch stone projects over the one below it. By this form it takes fast hold of the rubblework behind it. Above this rubble there is conftructed the inverted arch I e G of Portland Rone. This arch thares the pressure of the two adjoining arches, along with the arch stones in Y a and in G b. Thus all tend in the heart of this part of the pier. This is a very

built up to their intended height, the thrust of the Arch. arches fqueezes the rubble-work horizontally, after the mortar has fet, but before it has dried and acquired its utmost hardness. Its bond is broken by this motion, and it is fqueezed up, and never acquires its former firm-This is effectually prevented by the pressure exerted by the back of the inverted arch.

Above this counter arch is another mass of coursed rubble, and all is covered by a horizontal course of large blocks of Portland stone, butting against the back of the arch stone ZI and its corresponding one in the adjoining arch. This course connects the feet of the two arches, preserves the rubble work from too great compression, and protects it from soaking water. This last circumstance is important; for if the water which falls on the road-way is not carried off in pipes, it foaks through the gravel or other rubbish, rests on the mortar, and keeps it continually wer and foft. It cannot escape through the joints of good masoury, and therefore fills up this part like a funnel.

Supposing the adjoining arch fallen, and all tumbled off that is not withheld by its fituation, there will still remain in the pier a mass of about 3500 tons. The weight of the portion VY is about 2000 tons. The directions of the thrusts RY and YF are such, that it would require a load of 4500 tons on VY to overturn the pier round F. This exceeds VY by 2500 tons; a weight incomparably greater than any that can ever be

laid on it.

Such is the ingenious construction of Mr Mylne. It evidently proceeds on the principles recommended above; principles which have occurred to his experience and fagacious mind during the course of his extensive practice. We have feen attempts by other engineers to withstand the horizontal thrusts of the arch by means of counter arches inferted in the same manner as here, but extending much farther over the main arch; but they did not appear to be well calculated for producing this effect. A counter arch springing from any point between Y and V has no tendency to hinder that point from rifing by the finking of the crown; and fuch a counter arch will not refitt the precifely horizontal thrust so well as the straight course of Mr Mylne.

THE great incorporation of architects who built the Origin of cathedrals of Europe departed entirely from the styles the Gothic of ancient Greece and Rome, and introduced another, arches. in which areades made the principal part Not finding in every place quarries from which blocks could be raised in abandance of sufficient size for forming the farprojecting corniches of the Greek orders, they relinquished those proportions, and adopted a style of ornament which required no fuch projections: and having substituted arches for the horizontal architrave or lintel, they were now able to erect buildings of vast extent with spacious openings, and all this with very small pieces of stone. The form which had been adopted for a Christian temple occasioned many intersections of vaultings, and multiplied the arches exceedingly. Confrant practice gave opportunities of giving every possible variety of these intersections, and taught the art or batogether to compress and keep down the rubble-work lancing arch against arch in every variety of situation. An art fo multifarious, and fo much out of the road ufeful precaution; for it often happens, that when the of ordinary thought, could not but become an object centres of the arches are flruck, before the piers are of fond fludy to the architects most eminent for inge-

Dyle.

nuity and invention. Becoming thus the dupes of their closely we examine the ornaments of this architecture, Arch. when not necessary. At last arches became their principal ornament, and a wall or ceiling was not thought dreffed out as it should be till filled full of mock arches, croffing and butting on each other in every direction. In this process in their ceilings they found that the projecting mouldings, which we now call the Gothic tracery, formed the chief supports of the roofs. The plane furfaces included between those ribs were commonly vaulted with very small stones, seldom exceeding fix or eight inches in thickness. This tracery therefore was not a random ornament. Every rib had a position and direction that was not only proper, but even necessary. Habituated to this scientific arrangement of the mouldings, they did not deviate from it when they ornamented a smooth surface with mock arches; and in none of the highly ornamented ancient buildings will we find Degenera- any false positions. This is by no means the case in cy of that many of the modern imitations of Gothic architecture, even by our best architects. Ignorant of the directing principle, or not attending to it, in their flucco work, they please the unskilled eye with pretty radiated figures; but in these we frequently see such abutments of mouldings as would infallibly break the arches, if these mouldings were really performing their ancient office, and supporting a vaulting of considerable extent. Nay, this began even before the Gothic style was finally abandoned. Several inflances are to be found in the highly enriched vaultings of New College, and Christ Church in Oxford, in St George's Chapel at Windfor, and Henry VII.'s Chapel in Westminster.

We call the middle ages rude and barbarous; but there was furely much knowledge in those who could execute such magnificent and difficult works. The working drafts which were necessary for fuch varieties of oblique interfections must have required considerable skill, and would at present occupy many very expensive volumes of masons jewels, and carpenters manuals, and the like. All this knowledge was kept a profound iecret by the corporation, and on its breaking up we had

all to learn again.

There is no appearance, however, that those architects had fludied the theory of equilibrated arches. They had adopted an arch which was very ftrong, and permitted confiderable irregularities of preffure-we mean the pointed arch. The very deep mouldings with which it was ornamented, made the arch stones very Great skill long in proportion to the span of the arch. But they had fludied the mutual thrust of arches on each other bleft Gothic with great care; and they contrived to make every inarchitects. vention for this purpose become an ornament, so that the eye required it as a necessary part of the building. Thus we frequently fee small buildings having buttresses at the sides. These are necessary in a large vaulted building, for withstanding the outward thrust of the vanlting; but they are useless when we have a flat ceiling within. Pinnacles on the heads of the buttreffes are now confidered as ornaments; but originally they were put there to increale the weight of the buttress: even the great tower, in the centre of a cathedral, which now constitutes its great ornament, is a load almost indispensably necessary, for enabling the four principal columns to withstand the combined thrust of the aisles, of the nave, and transepts. In short, the more SUPPL. VOL. I. Part I.

own ingenuity, they were fond of displaying it even the more shall we perceive that they are essential parts, or derived from them by imitation: and the more we confider the whole style of it, the more clearly do we fee that it is all deduced from the relish for arcades, indulged in the extreme, and pushed to the limit of posfibility of execution.

> THERE is another species of arch which must not be Dome or overlooked, namely, the Dome or Curola, with all its cupola varieties, which include even the pyramidal steeple or

It is evident that the erection of a dome is also a scientific art, proceeding on the principles of equilibration, and that these principles admit and require the fame or fimilar modifications, in consequence of the cohesion and friction of the materials. At first fight, too. a dome appears a more difficult piece of work than a plain arch; but when we observe potters kilns and glasshouse domes and cones, of vast extent, erected by ordinary bricklayers, and with materials vaftly inferior in fize to what can be employed in common arches of equal extent, we must conclude that the circumstance of curvature in the horizontal direction, or the abutment of a circular base, gives some assistance to the artist. Of this we have complete demonstration in the case of the cone. We know that a vaulting in the form of a pent roof could not be executed to any confiderable extent, and would be extremely hazardous, even in the smallest dimensions; while a cone of the greatest magnitude can be raifed with very fmall flones, provided only that we prevent the bottom from flying out, by a hoop, or any fimilar contrivance. And when we think a little of the Of eaffer matter, we fee plainly, that if the horizontal fection be continueperfectly round, and the joints be all directed to the tion than axis, they all equally endeavour to slide inwards, while arch. no reason can be offered why any individual stone should prevail. They are all wedges, and operate only as wedges. When we confider any fingle course, therefore, we fee that it cannot tall in, even though it may be part of a curve which could not fland as a common arch; nay, we fee that a dome may be constructed, having the convexity of the curve, by the revolution of which it is formed, turned towards the axis, fo that the outline is concave. We shall afterwards find that this is a stronger dome by far than if the convexity were outwards, as in a common arch. We see also that a cone may be loaded on the top with the greatest weight, without the finallest danger of forcing it down, to long as the bottom course is firmly kept from bursting outwards. The stone lanthern on the top of St Paul's cathedral in London weighs feveral hundred tons, and is carried by a brick cone of eigliteen inches thick, with perfect fafety, as long as the bottom course is prevented from bursting outwards. The reason is evident: The pressure on the top is propagated along the cone in the direction of the flant fide; and, fo far from having any tendency to break it in any part, it tends rather to prevent its being broken by any irregular preffure from foreign causes.

For the same reasons the octagonal pyramids, which proper conform the spires of Gothic architecture, are abundantly ruction of firm, although very thin. The sides of the spire of edagonal Salifbury cathedral are not eight inches thick after the pyramids. octagon is fully formed. It is proper, however, to di-

Arch.

cause the projecting mouldings which run along the angles are the abutments on which the whole pannel depends. A confiderable art is necessary for supporting those pannels or fides of the octagon which spring from the angles of the square tower. This is done by beginning a very narrow pointed arch on the square tower at a great diftance below the top; so that the legs of the arch being very long, a straight line may be drawn from the top of the keystone of the arch through the whole arch stones of the legs. By this disposition the thrusts arising from the weight of these four pannels are made to meet on the massive masonry in the middle of the sides of the tower, at a great distance below the springing of the spire. This part, being loaded with the great mass of perpendicular wall, is fully able to withftand the horizontal thrust from the legs of those arches. In many spires these thrusts are still farther refifted by iron bars which cross the tower, and are hooked into pieces of brais firmly bedded in the majonry of

Examples ftruction.

There is much nice balancing of this kind to be obof fuch con-ferved in the highly ornamented open spires; such as those of Brussels, Mechlin, Antwerp, &c. We have not many of this fort in Britain. In those of great magnitude, the judicious eye will discover that parts, which a common spectator would consider are mere ornaments, are necessary for completing the balance of the whole. Tall pinnacles, nay, even pillars carrying enta. blatures and pinnacles, are to be feen standing on the middle of the flender leg of an arch. On examination, we find that this is necessary, to prevent the arch from fpringing upwards in that place by the pressure at the crown. The fleeple of the cathedral of Mechlin was the most elaborate piece of architecture in this taste in the world, and was really a wonder; but it was not calculated to withstand a bombardment, which destroyed it in 1578.

Such frequent examples of irregular and whimfical buildings of this kind, show that great liberties may be taken with the principle of equilibration without risk, if we take care to secure the base from being thrust outwards. This may always be done by hoops, which can be concealed in the masonry; whereas, in common arches, these ties would be visible, and would offend the

principles

It is now time to attend to the principle of equilibrium, as it operates in a fimple circular dome, and to determine the thickness of the vaulting when the curve is given, or the curve when the thickness is given. Plate II. Therefore, let B b A (fig. 17.) be the curve which produces the dome by revolving round the vertical axis AD. Stability of We shall suppose this curve to be drawn through the a dome de- middle of all the arch stones, and that the courfing or horizontal joints are every where perpendicuar to the curve. We shall suppose (as is always the case) that the thickness KL, HI, &c. of the arch stones is very fmall in comparison with the dimensions of the arch. If we consider any portion HA b of the dome, it is plain that it presses on the course, of which HL is an arch stone, in a direction b C perpendicular to the joint HI, or in the direction of the next superior element Bb of the curve. As we proceed downwards, course after course, we see plainly that this direction must

red the joints to the axis of the pyramid, and to make change, because the weight of each course is superadded Arch. the courfing joints perpendicular to the flant fide, be- to that of the portion above it, to complete the preffure on the course below. Through B draw the vertical line BCG, meeing & b, produced in C. We may take bc to press the pressure of all that is above it, propagated in this direction to the joint KL. We may also Suppose the weight of the course HL united in b, and acting on the vertical. Let it be represented by b F. If we form the parallelogram b FGC, the diagonal b G will reprefent the direction and intenfity of the whole pressure on the joint KL. Thus it appears that this pressure is continually changing its direction, and that the line, which will always coincide with it, must be a curve concave downward. If this be precifely the curve of the dome, it will be an equilibrated vaulting; but so far from being the strongest form, it is the weakest, and it is the limit to an infinity of others, which are all stronger than it. This will appear evident, if we suppose that b G does not coincide with the curve A & B, but passes without it. As we suppose the arch stones to be exceedingly thin from infide to outlide, it is plain that this dome cannot fland, and that the weight of the upper part will press it down, and spring the vaulting outwards at the joint KL. But let us suppose, on the other hand, that b G falls within the curvelineal element b B. This evidently tends to push the arch stone inward, toward the axis, and would cause it to slide in, fince the joints are supposed perfectly smooth and sipping. But fince this takes place equally in every stone of this course, they must all abut on each other in the vertical joints, squeezing them firmly together. Therefore, refolving the thrust b G into two, one of which is perpendicular to the joint KL, and the other parallel to it, we fee that this last thrust is withstood by the vertical joints all around, and there remains only the thrust in the direction of the curve. Such a dome must therefore be firmer than an equilibrated dome, and cannot be fo eafily broken by overloading the upper part. When the curve is concave upwards, as in the lower part of the figure, the line bC always falls below bB, and the point C below B. When the curve is concave downwards, as in the upper part of the figure, $b \, \mathbb{C}'$ passes above, or without $b \, \mathbb{B}$. The curvature may be fo abrupt, that even b' G' shall pass without 'b B, and the point G' is above B'. It is also evident that the force which thus binds the stones of a horizontal course together, by pushing them towards the axis, will be greater in flat domes than in those that are more convex; that it will be still greater in a cone; and greater still in a curve whose convexity is turned inwards: for in this last case the line b G will deviate most remarkably from the curve. Such a dome will fland (having polished joints) if the curve springs from the base with any elevation, however small; nay, since the friction of two pieces of stone is not less than half of their mutual pressure, such a dome will stand, although the tangent to the curve at the bottom should be horizontal, provided that the horizontal thrust be double the weight of the dome, which may easily be the case if it do not rife high.

Thus we see that the stability of a dome depends on Different very different principles from that of a common arch, from that and is in general much greater. It differs also in and of a comand is in general much greater. It differs also in ano-mon arch. ther very important circumstance, viz. that it may be open in the middle : for the uppermost course, by tend-

ing equally in every part to slide in toward the axis, presses all together in the vertical joints, and acts on the next course like the key stone of a common arch. Therefore an arch of equilibration, which is the weakest of all, may be open in the middle, and carry at top another building, fuch as a lanthern, if its weight do not exceed that of the circular fegment of the dome that is omitted. A greater load than this would indeed break the dome, by caufing it to spring up in some of the lower courles; but this load may be increased if the curve is flatter than the curve of equilibration: and any load whatever, which will not crush the stones to powder, may be set on a truncate cone, or on a dome formed by a curve that is convex toward the axis; provided always that the foundation be effectually prevented from flying out, either by a hoop, or by a sufficient mass of solid pier on which it is set. We have mentioned the many failures which happened to the dome of St Sophia in Constantinople. We imagine that the thrust of the great dome, bending the eastern arch outward as foon as the pier began to yield, destroyed the half dome which was leaning on it, and thus, almost in an instant, took away the eastern abutment. We think that this might have been prevented, without any change in the injudicious plan, if the dome had been hooped with iron, as was practifed by Michael Angelo in the vaftly more ponderous dome of St Peter's at Rome, and by Sir Christopher Wren in the cone and the inner Excellency dome of St Paul's at London. The weight of the of the dome latter confiderably exceeds 3000 tons, and they occaof St Paul's fion a horizontal thrust which is nearly half this quantity, the elevation of the cone being about 60°. This being distributed round the circumference, occasions a

ftrain on the hoop $=\frac{7}{2\times22}$ of the thrust, or nearly 238 tons. A square inch of the worst iron, if well

forged, will carry 25 tons with perfect fafety; therefore a hoop of 7 inches broad and 11 inches thick will completely secure this circle from bursting outwards. It is, however, much more completely secured; for besides a hoop at the base of very nearly these dimensions, there are hoops in different courses of the cone which bind it into one mass, and cause it to press on the piers in a direction exactly vertical. The only thrusts which the piers sustain are those from the arches of the body of the church and the transepts. These are most judiciously directed to the entering angles of the building, and are there refifted with insuperable force by the whole lengths of the walls, and by four folid maffes of masonry in the corners. Whoever considers with attention and judgment the plan of this cathedral, will fee that the thrusts of these arches, and of the dome, are incomparably better balanced than in St Peter's church at Rome. But to return from this fort of digression.

We have feen that if b G, the thrust compounded of Theory of the thrust b C, exerted by all the courses above HLLK, the curves proper for and if the force bF, or the weight of that course, be everywhere coincident with bB, the element of the curve, we shall have an equilibrated dome; if it falls within it, we have a dome which will bear a greater load; and if it falls without it, the dome will break at the joint. We must endeavour to get analytical expresfions of these conditions. Therefore draw the ordinates $b \circ b''$, BDB'', CdC''. Let the tangents at b and b'' bc, and complete the parallelogram MONP, and draw OQ perpendicular to the axis, and produce b F, cutting the ordinates in E and e. It is plain that MN is to MO as the weight of the arch HAb to the thrust bc which it exerts on the joint KL (this thrust being propagated through the course HILK); and that MQ, or its equal be, or & d, may represent the weight of the

Let AD be called x, and DB be called y. Then $be = \kappa$, and eC = y (because be is in the direction of the element βb). It is also plain, that if we make yconstant, BC is the second fluxion of x, or BC = x, and be and BE may be confidered as equal, and taken indifcriminately for x. We have also $b = \sqrt{x^2 + y^2}$. Let d be the depth or thickness HI of the arch stones. Then $d\sqrt{x^2 + y^2}$ will represent the trapezium HL; and since the circumference of each course increases in the proportion of the radius y, $dy \sqrt{x^2 + y^2}$ will express the whole course. If f be taken to represent the fum or aggregate of the quantities annexed to it, the formula will be analogous to the fluent of a fluxion, and $\int ds \sqrt{\dot{x}^2 + \dot{y}^2}$ will represent the whole mass, and also the weight of the vaulting, down to the joint HI. Therefore we have this proportion $\int dy \sqrt{\dot{x}^2 + \dot{y}^2}$ $: dy \sqrt{\dot{x}^2 + \dot{y}^2} = be: b \text{ F}, = be: C \text{ G}, = \delta d: C \text{ G},$ $= \dot{x}: C \text{ G}. \text{ Therefore } C \text{ G} = \frac{dy \dot{x} \sqrt{\dot{x}^2 + \dot{y}^2}}{\int dy \sqrt{\dot{x}^2 + \dot{y}^2}}.$ If the curvature of the dome be precifely fuch as

puts it in equilibrium, but without any mutual preffure in the vertical joints, this value of OG must be equal to CB, or to x, the point G coinciding with B. This

condition will be expressed by the equation $\frac{dy \times \sqrt{x^2 + y^2}}{\int dy \sqrt{x^2 + y^2}}$ = x, or, more conveniently, by $\frac{dy}{\int dy} \sqrt{\frac{x^2 + y^2}{x^2 + y^2}} = \frac{x}{x}$ But this form gives only a tottering equilibrium, inde-

pendent of the friction of the joints and the cohesion of the cement. An equilibrium, accompanied by some firm stability, produced by the mutual pressure of the verti-

cal joints, may be expressed by the formula $\frac{dy}{\sqrt{x^2 + y^2}}$ $\frac{dy}{\sqrt{x^2 + y^2}}$ $\frac{x}{\sqrt{x^2 + y^2}}$ $\frac{x}{\sqrt{x^2 + y^2}}$ $\frac{x}{\sqrt{x^2 + y^2}}$ $\frac{x}{\sqrt{x^2 + y^2}}$ where t is some

variable positive quantity, which increases when & increafes. This last equation will also express the equilibrated dome, if t be a constant quantity, because in

this case $t_{-is} = 0$.

Since a firm flability requires that $\frac{d_y \cdot x}{dy} \sqrt{x^2 + y^2}$ fhall greater than $\frac{d_y \cdot x}{dy} \sqrt{x^2 + y^2}$

be greater than a, and CG must be greater than CB: Hence we learn, that figures of too great curvature, meet the axis in M, and make MO, MP, each equal to whose sides descend too rapidly, are improper. Also,

domes.

fince stability requires that we have $\frac{dy x}{x^2 + y^2}$ Arch.

greater than $\int dy \sqrt{x^2 + y^2}$, we learn that the upper part of the dome must not be made very heavy. This, by diminishing the proportion of b F to bC, diminishes the angle c b G, and may fet the point G above B, which will infallibly spring the dome in that place. We see here also, that the algebraic analysis expresses that peculiarity of dome-vaulting, that the weight of the upper part may even be suppressed.

The fluent of the equation $\frac{dy\sqrt{x^2+y^2}}{\int dy\sqrt{x^2+y^2}} = \frac{x}{x} + \frac{t}{t}$

is most easily found. It is $L \int dy \sqrt{x^2 + y^2} = L x +$ Lt, where L is the hyperbolic logarithm of the quantity annexed to it. If we confider y as constant, and correct the fluent so as to make it nothing at the vertex, it may be expressed thus, I. $\int dy \sqrt{\dot{x}^2 + \dot{y}^2} - \text{L.} a = \text{L.} \dot{x}$ $-\text{L.} \dot{y} + \text{L.} t$. This give us $\text{L.} \int \frac{dy}{\sqrt{\dot{x}^2 + \dot{y}^2}} = \text{L.} \frac{x}{y}t$, and therefore $\int \frac{dy}{\sqrt{\dot{x}^2 + \dot{y}^2}} = t \frac{\dot{x}}{y}$.

This last equation will easily give us the depth of vaulting, or thickness d of the arch, when the curve is given. For its fluxion is $\frac{dy\sqrt{\dot{x}^2+\dot{y}^2}}{a} = \frac{\dot{t}\dot{x} + \dot{x}\dot{x}}{\dot{y}}$,

and $d = \frac{a \dot{t} \dot{x} + a t \dot{x}}{y \dot{y} \sqrt{\dot{x}^2 + \dot{y}^2}}$, which is all expressed in known

quantities; for we may put in place of t any power or function of x or of y, and thus convert the expression into another, which will still be applicable to all forts of

Instead of the second member $\frac{x}{t} + \frac{t}{t}$ we might em-

ploy $\frac{p \times p}{1 \times p}$, where p is some number greater than unity. This will evidently give a dome having stability; because the original formula $\frac{dy\dot{x}\sqrt{\dot{x}^2+\dot{y}^2}}{\int dy\sqrt{\dot{x}^2+\dot{y}^2}}$ will then be

greater than \dot{x} . This will give $d = \frac{p \, a \, \dot{x} \, p - 1 \, \dot{x}}{y \, \dot{y}^{\dot{p}} \, \sqrt{\dot{x}^2 + y^2}}$. Each of these forms has its advantages when applied to par-

ticular cases. Each of them also gives $d = \frac{a \dot{x}}{y \dot{y} \sqrt{\dot{x}^2 + \dot{y}^2}}$ when the curvature is such as is in precise equilibrium.

And, lastly, if d be constant, that is, if the vaulting be of uniform thickness, we obtain the form of the curve, because then the relation of x to x and to y is given.

The chief use of this analysis is to discover what curves are improper for domes, or what portions of given curves may be employed with fafety. Domes are generally built for ornament; and we fee that there is great room for indulging our fancy in the choice. All curves which are concave outwards will give domes of great firmness.: They are also beautiful. The Gothic dome, whose outline is an undulated curve, may be made Arch. abundantly firm, especially if the upper part be convex and the lower concave outwards.

The chief difficulty in the case of this analysis arises from the necessity of expressing the weight of the incumbent part, or $\int dy \sqrt{x^2 + y^2}$. This requires the measurement of the conoidal surface, which, in most cases, can be had only by approximation by means of infinite feriefes We cannot expect that the generality of practical builders are familiar with this branch of mathematics, and therefore will not engage in it here; but content ourselves with giving such instances as can be understood by such as have that moderate mathematical knowledge which every man should possess who takes the name of engineer.

The surface of any circular portion of a sphere is very eafily had, being equal to the circle defcribed with a radius equal to the chord of half the arch. This ra-

dius is evidently = $\sqrt{\kappa^2 + y^2}$. In order to discover what portion of a hemisphere may be employed (for it is evident that we cannot employ the whole) when the thickness of the vaulting is uniform, we may recur to the equation or formula

 $\frac{dy \times \sqrt{x^2 - y^2}}{x} = \int dy \sqrt{x^2 + y^2}.$ Let a be the radius of the hemisphere. We have $\kappa = \frac{ayy}{\sqrt{a^2 - y^2}}$, and κ $= \frac{a^2 \dot{y}^2}{a^2 - y^{-\frac{3}{4}}}.$ Substituting these values in the formula, we obtain the equation $y^2 \sqrt{a^2 - y^2} = \int \frac{a^2 y \dot{y}}{\sqrt{a^2 - y^2}}.$ We

eafily obtain the fluent of the fecond member = a3 $-a^2\sqrt{a^2-y^2}$, and $y=a\sqrt{-\frac{1}{2}+\sqrt{\frac{5}{4}}}$. Therefore if the radius of the sphere be 1, the half breadth of the dome must not exceed $\sqrt{-\frac{1}{2} + \sqrt{\frac{5}{4}}}$, or 0,786, and the height will be 618. The arch from the vertex is

about 51° 49'. Much more of the hemisphere cannot stand, even though aided by the cement, and by the friction of the courfing joints. This last circumstance, by giving connection to the upper parts, causes the whole to prefs more vertically on the course below, and thus diminishes the outward thrust; but it at the same time diminishes the mutual abutment of the vertical joints, which is a great cause of firmness in the vaulting. A Gothic dome, of which the upper part is a portion of a sphere not exceeding 45° from the vertex, and the lower part is concave outwards, will be very strong, and not ungraceful.

But the public tafte has long rejected this form, and Dome of feems rather to felect more elevated domes than this por-St leter's tion of a sphere; because a dome, when seen from a at Rome. fmall distance, always appears flatter than it really is. The dome of St Peter's is nearly an ellipsoid externally, of which the longer axis is perpendicular to the horizon. It is very ingeniously constructed. It springs from the base perpendicularly, and is very thick in this part. After rifing about 50 feet, the vaulting separates into two thin vaultings, which gradually separate from each other. These two shells are connected together by thin partitions, which are very artificially dovetailed in both, and thus form a covering which is extremely stiff, while it is very light. Its great stiffness was necessary for enabling the crown of the dome to carry the elegant stone lanthern

form of a

dome.

lanthern with fafety. It is a wonderful performance, hemisphere, and may be broken off at any horizontal Archand has not its equal in the world; but it is an enormous load in comparison with the dome of St Paul's, and this even independent of the difference of fize. If they were of equal dimensions, it would be at least five times as heavy, and is not fo firm by its gravity; but as it is connected in every part by iron bars (lodged in the folid masonry, and well secured from the weather by having lead melted all round them), it bids fair to last

for ages, if the foundations do not fail.

It a circle be described round a centre placed any-Plate II. where in the transverse axis AC (fig. 18. No 1.) of an ellipse, so as to touch the ellipse in the extremities B, b, of an ordinate, it will touch it internally, and the circular arch Bab will be wholly within the elliptical arch BA b. Therefore, if an elliptical and a spherical vaulting spring from the same base, at the same angle with the horizon, the spherical vaulting will be within the elliptical, will be flatter and lighter, and therefore the weight of the next course below will bear a greater proportion to the thrust in the direction of the curve; therefore the spherical vaulting will have more stability. On the contrary, and for fimilar reasons, an oblate elliptical vaulting is preferable to a spherical vaulting fpringing with the same inclination to the horizon. (Fig. 18. N° 2.)

Dimensions Persuaded, that what has been said on the subject of the best convinces the reader that a vaulting perfectly equilibrated throughout is by no means the best form, provided that the base is secured from separating, we think it unnecessary to give the investigation of that form, which has a confiderable intricacy; and shall content ourselves with merely giving its dimensions. The thickness is supposed uniform The numbers in the first column of the table express the portion of the axis counted from the vertex, and those of the second column are the

lengths of the ordinates.

'The curve delineated in fig. 19. is formed according to these dimensions, and appears destitute of gracefulnels; because its curvature changes abruptly at a little diffance from the vertex, so that it has some appearance of being made up of different curves pieced together. But if the middle be occupied by a lanthern of equal, or of smaller weight, this defect will cease, and the whole will be elegant, nearly relembling the exterior dome of St Paul's in London.

It is not a small advantage of dome-vaulting that it is lighter than any that can cover the same area. If, moreover, it be spherical, it will admit considerable varieties of figure, by combining different spheres. Thus, a dome may begin from its base as a portion of a large

courfe, and then a fimilar or a greater portion of a imaller sphere may spring from this course as a base. It also bears being intersected by cylindrical vaultings in every direction, and the interfections are exact circles, and always have a pleasing effect. It also springs most gracefully from the heads of small piers, or from the corners of rooms of any polygonal shape; and the arches formed by its interfections with the walls are always circular and graceful, forming very handlome spandrels in every position. For these reasons Sir Christopher Wren employed it in all his vaultings, and he has exhibited many beautiful varieties in the transepts and the aifles of St Paul's, which are highly worthy of the observation of architects. Nothing can be more graceful than the vaultings at the ends of the north and fouth tranfepts, especially as finished off in the fine inside view published by Gwynn and Wale.

We conclude this article with observing, that the Effects of connection of the parts, ariling from cement and from friction in friction, has a great effect on dome vaulting. In the tome vaultsame way as in common arches and cylindrical vaulting, ing. it enables an overload on one place to break the dome in a distant place. But the resistance to this effect is much greater in dome vaulting, because it operates all round the overloaded part. Hence it happens that domes are much less shattered by partial violence, such as the falling of a bomb or the like. Large holes may be broken in them without much affecting the rest; but, on the other hand, it greatly diminishes the strength which should be derived from the mutual pressure in the vertical joints. Friction prevents the sliding in of the arch stones which produces this mutual pressure in the vertical joints, except in the very highest courses, and even there it greatly diminishes it. These causes make a great change in the form which gives the greatest ftrength; and as their laws of action are but very imperfectly understood as yet, it is perhaps impossible, in the present state of our knowledge, to determine this form with tolerable precision. We see plainly, however, that it allows a greater deviation from the best form than the other kind of vaulting, and domes may be made to rife perpendicular to the horizon at the base, although of no great thickness; a thing which must not be attempted in a plane arch. The immense addition of strength which may be derived from hooping, largely compensates for all defects; and there is hardly any bounds to the extent to which a very thin dome vaulting may be carried, when it is hooped or framed in the direction of the horizontal courses. The roof of the Halle du Bled at Paris is but a foot thick, and its diameter is more than 200, yet it appears to have abundannt strength. It is, on the whole, a noble specimen of architecture.

WE must not conclude this article without taking The iron notice of that magnificent and elegant arch which has bridge at been erected in cast iron at Weremouth, near Sunder-describedland, in the county of Durham. The inventor and architect is ROWLAND BURDON, Eig; one of the reprefentatives of that county in the present Parliament.

This arch is a segment of a circle whose diameter is about 444 feet. The ipan or cord of the arch is 236 feet, and its versed fine or spring is 34 feet. It springs at the elevation of 60 feet from the surface of the ri-

Advantages of domevaulting.

ver at low water, fo that veffels of 200 or perhaps 300 tons burden may pass under it in the middle of the

stream, and even 50 feet on each side of it.

The sweep of the arch consists of a series of frames of cast iron, which butt on each other, in the same manner as the voussoirs of a stone arch. One of these frames or blocks (as we shall call them in future) is repre-Place IV. fented in fig. 1. as feen in front. It is cast in one piece; and confifts of three pieces or arms BC, BC, BC, the middle one of which is two feet long, the upper being fomewhat more, and the lower fomewhat lefs, because their extremities are bounded by the radius drawn from the centre of the arch. These arms are four inches square, and are connected by other pieces KL, of such length that the whole length of the block is five feet in the direction of the radius. Each arm has a flat groove on each fide, which is expressed by the darker shading, three inches broad and three fourths of an inch deep. A fection of this block, through the middle of KL, is represented by the light-shaded part BBB, in which the grooves are more diffinctly perceived. These grooves are intended for receiving flat bars of malleable iron, which are employed for connecting the different blocks with each other. Fig. 2. represents two blocks united in this manner. For this purpose each arm has two square bolt holes. The ends of the arms being nicely trimmed off, so that the three ends butt equally close on the ends of the next block; and the bars of hammered iron being also nicely fitted to their grooves, so as to fill them completely, and have their bolt-holes exactly corresponding to those in the blocks, they are put together in such a manner that the joints or meetings of the malleable bars may fall on the middle between the boltholes in the arms. Flat headed bolts of wrought iron are then put through, and keys or forelocks are driven through the bolt tails, and thus all is firmly wedged together, binding each arm between two bars of wrought iron. These bars are of fuch length as to connect several blocks.

In this manner a feries of about 125 blocks are joined together, fo as to form the precise curve that is intended. This feries may be called a rib, and it stands in a vertical plane. The arch confifts of fix of these ribs, distant from each other five feet. These ribs are connected together so as to form an arch of 32 feet in

breadth, in the following manner.

Fig. 3. represents one of the bridles or cross pieces which connect the different ribs, as it appears when viewed from below. It is a hollow pipe of cast iron, four inches in diameter, and has at each end two projecting shoulders, pierced with a bolt-hole near their extremities, so that the distance between the bolt-holes in the shoulders of one end is equal to the distance between the holes in the arms of the blocks, or the holes in the wrought iron bars. In the middle of the upper and of the underfide of each end may be observed a iquare prominence, more lightly shaded than the rest. These projections also advance a little beyond the flat of the shoulders, forming between them a shallow notch, about an inch deep, which receives the iron of the arms, where they butt on each other, and thus gives an additional firmness to the joint. The manner in which the arms are thus graiped by these notches in the bridles is more definely seen in fig. 2. at the letter H in the middle of the upper rail.

The rib having been all trimmed and put together. Arch. so as to form the exact curve, the bolts are all taken out, and the horizontal bridles are then fet on in their places, and the bolts are again put in and made falt by the forelocks. The bolts now pass through the shoulders of the bridles, through the wrought iron bars, and through the cast iron arm that is between them, and the forelocks bind all fast together. The manner in which this connection is completed is distinctly scen in fig. 2. which shows in pertpective a double block in front, and a fingle block behind it The butting joints of the two front blocks are at the letters E, E, E; the holes in the shoulders of the horizontal cross picces are

This conftruction is beautifully fimple and very judi- Its concious. A vast addition of strength and of stiffness is struction simple and procured by lodging the wrought iron bars in grooves judicious, formed in the cast iron rails; and for this purpose it is of great importance to make the wrought iron bars fill the grooves completely, and even to be fo tight as to require the force of the forelocks to draw them home to the bottom of the grooves. There can be no doubt but that this arch is able to withstand an enormous preffure, as long as the abutments from which it fprings do not yield. Of this there is hardly any risk, because they are masses of rock, faced with about four or five yards (in some places only) of solid block masonry. The mutual thruits of the trames are all in the direction of the rails, so that no part bears any transverse strain. We can hardly conceive any force that can overcome the strength of those arms by pressure or crushing them. The manner in which the frames are connected into one rib, effectually secures the butting joints from slipping; and the accuracy with which the whole can be executed, secures us against any warping or deviation of a rib

from the vertical plane. But when we confider the prodigious span of this arch, and reflect that it is only five feet thick, it should feem that the most perfect equilibration is indispensably necessary. It is but like a film, and must be so supple that an overload on any part must have a great ten-dency to bend it, and to cause it to rise in a distant part; and this effect is increased by the very firm-ness with which the whole sticks together. The overloaded part acts on a diffant part, tending to break it with all the energy of a long lever. This can be prevented only by means of the stiffness of the distant part. It is very true, the arch cannot break in the extrados except by tearing afunder the wrought iron bars which connect the blocks along the upper rail, and each of these requires more than a hundred tons to tear it afunder; yet an overload of five tons on any rib at its middle will produce this firain at twenty feet from the fides, supposing the fides held firm in their position. It were defirable therefore that something were done to stiffen the arch at the fides, by the manner of filling up the spandrels, or space between the arch and the roadway. This is filled up in a manner that is extremely Though in

light and pleafing to the eye, namely, by large cast iron one particircles, which touch the extrados of the arch and touch bb, perthe road-way. The road-way rests on them as on fo haps of immany hoops, while they rest on the back of the arch, provement, and also touch each other laterally. We cannot think that this contributes to the strength of the arch; for these hoops will be easily compressed at the points of

TRON BRIDGE

contact, and, changing their shape, will oppose very rant and barbarous?" This question has occupied the Architectitle resistance. We think that this part of the architecture. might have been greatly stiffened and strengthened, by the Gothic style of building, some to necessity, and connecting it with the road way by truffed frames, in others to an imitation of the works of nature. That, the same way that a judicious carpenter would have fra- where materials are bad, larger edifices can be erected med a roof. If a strong cast iron pillar had been made in the Gothic than in the Grecian style, has been made to rest on the arch at about 20 feet from the impost, and been placed in the direction of a radius, the top of this pillar might have been connected by a diagonal bar of wrought iron with the impost of the arch, and with the crown of the arch by another string or bar of the fame materials. These two ties would cause the radial, and the double row of clustered pillars composed of pillar to press strongly on the back of the arch, and they must be torn afunder before it could bend in that place in the smallest degree. Supposing them of the fame dimensions as the bars in the arms, their position would give them near ten times the force for refifting the ilrain produced by an overload on the crown.

This beautiful arch contains only 260 tons of iron, of which about 55 are wrought iron. The superstructure is of wood, planked over a-top. This floor is covered with a coating of chalk and tar, on which is laid the materials for the carriage road, confisting of marle, limestone, and gravel, with foot-ways of flag-stones at the fides. The weight of the whole did not exceed a thousand tons; whereas the lightest stone arch which could have been erected would have weighed fifteen thousand. It was turned on a very light but stiff scaffolding, most judiciously constructed for the prefervation of its form, and for allowing an uninterrupted passage for the numerous ships and small craft which frequent the bufy harbour of Sunderland. The mode of framing the arch was so simple and easy, that it was put up in ten days! without an accident; and when all was finished, and the scaffolding removed, the arch did not fenfibly change its form. The whole work was executed in three years, and cost about L 26,000.

ARCHITECTURE is an art of fo much importance, and capable of fo many embellishments, as to have employed the attention and talents of men of fcience in almost every age, and in every country. It is generally thought to have been carried to the utmost perfection among the Greeks and Romans; and it has been the aim of the most eminent architects of modern times to imitate with fidelity the buildings of those accomplished nations. There is, however, another species of architecture, which was introduced into Europe in the middle ages, and is of such a nature as to ffrike every unprejudiced observer with admiration and afonishment. The architecture to which we allude has been called, perhaps with little propriety,

Gothic Architecture. It is that which is to be viewed in all our ancient cathedrals, and in other large buildings, which have been erected from the middle of the 12th to the beginning of the 16th century. That fuch edifices have been constructed on principles of science, has been shown elsewhere (see Roof, Encycl. and ARCH, in this Suppl.): but a question still presents itself to the inquisitive mind, " How came fuch structures to be thought of by a people whom we are accustomed to call igno-

fufficiently evident in the articles to which we have referred; and that necessity is the parent of invention, is an adage which has been too long received to be now called in question. But whence came the peculiarities of the Gothic ornaments in building, the pointed arch, flender shafts, which, reaching from the ground almost to the roof of the building, are there spread out in all directions, forming the ribs or groins of a vaulted roof?

The most satisfactory solution of this question which we have feen, is in a memoir published in the fourth volume of the Transactions of the Royal Society of Edinburgh, by Sir James HALL, Bart. with whose permission the following abstract is laid before our readers.

"Although the connection between beauty and utility be still involved in such obscurity, that we are unable to decide concerning the universality of that connection, of one thing we are certain, that, in a work intended to answer some useful purpose, whatever visibly counteracts that purpose always occafions deformity. Hence it is, that, even where ornament is principally intended, the oftenfibly useful object of the work, if it have any such, must be provided for, in the first place, in preference to every other consideration.

"But in most useful works, some parts occur, the shape of which is quite indifferent with respect to the proposed utility, and which, therefore, the artist is at liberty to execute as he pleases: a liberty which has opened a wide field to the taste and invention of ingenious men of every age and country, who have turned their attention to the composition of ornaments; and whose exertions have been more or less influenced by the state of civilization in which they lived. It would feem, however, if we may judge by those various efforts, that little has been effected by mere human ingenuity; fince we fee that recourse has been had, almost univerfally, to nature, the great and legitimate fource of beauty; and that ornament has been attained by the imitation of objects, to which she has given a determinate and characteristic form.

"Where the materials employed are themselves posfessed of variety and elegance, the attainment of this object requires little or no alteration of their natural forms. Thus cups are made of shells, of cocca nuts, or of ostrich eggs; the character and beauty of which depend upon the natural form of the materials: and in the case of the bottles used by the Roman Catholic pilgrims, an example occurs of an utenfil, in which the natural form has undergone little or no variation, fince it confifts of the hard outward skin of a gourd, of the same shape in which it grew upon the plant (A). This last class of forms has been introduced, by imitation, into works

⁽A) "Even in this case, however, the natural form undergoes a certain degree of modification, by the device employed to produce the neck of the bottle. The fruit, while small and tender, is surrounded with a string, which remaining during its growth, prevents the part, thus bound, from fwelling with the reft."

cups in the form of those made of shells, and fruit-

dishes of stone ware in the form of baskets.

"As stone is not naturally possessed of any peculiar shape, and as the uleful object proposed, by structures formed of of it, may be accomplished in various ways, very great latitude is left to the invention of the artift. We see, accordingly, that in every country where much refinement has been introduced, great pains have been beflowed in ornamenting frome buildings with figures representing various natural objects; whilst the building itself has been executed in imitation of a structure, composed of materials which naturally possess a determinate and characteristic form. Such was the method followed by the architects of ancient Greece, who conflructed temples, and other public edifices, in imitation of a rustic fabric, composed of square beams, supported upon round posts or stems of trees, and who derived the numerous ornaments of that beautiful flyle from circumstances which would naturally take place in such a

"A faint and distant resemblance, however, of the original, has generally been found to answer all the end proposed by the imitation; a resemblance, which may fometimes be traced in the general distribution of the edifice, fometimes in its minute parts, and not unfre-

quently in both.

. But the forms of nature thus introduced have been greatly modified by those of masonry. For though stone is by nature shapeless, yet, in the course of practice, many peculiar forms have been long established, and currently employed, in working it; fuch as ftraight lines, plain furfaces, square angles, and various mouldings used to soften the effect of abrupt terminations: all of which, originating in motives of mechanical convenience, and of fimple ornament, had, in very early times, been appropriated to masonry, and considered as effential in every finished work of stone; so that, when the imitation of nature was introduced, these masonic forms still maintained their ground, and, being blended with the forms of nature, the two classes reciprocally modified each other.

"This combination of art with nature, of which we fee the most perfect example in the Corinthian capital, produces what are called architectonic forms, in which the variety of nature, being subjected to the regularity of art, the work acquires that peculiar character which, in a natural object, we confider as offensive, under the name of formality; but which, in architecture, we admire as a beauty, under the name of fymmetry: thus, we reprobate the formality of an avenue, and praile the

fymmetry of a colonnade.

" Such is the nature of architectonic imitation; a device which probably originated in accident, but to which architecture is indebted for its highest attain-

ments."

As the stone edifices of ancient Greece were conftrusted in imitation of a wooden fabric, composed of fourre beams laid at right angles on round posts or flems of trees. Sir James conceives that the Gothic fabrics with pointed arches have been executed in imitation of a ruftic dwelling, conftructed in the following manner: Suppose a set of round posts driven frmly in to the ground in two opposite rows, the interval between the neighbouring posts in the same row being

Architec- composed of shapeless materials. Thus we have filver equal to that between the rows, and each post being Architecraifed above the ground to a height equal to three of those intervals: then a set of long and flexible rods of willow being applied to each post, let them be thrust into the ground at its base, and bound to it by two tyings, one near the ground, and another at two-thirds of its height; the rods being left loofe from this last point upwards, and free to be moved in any direction. Let three rods be connected with each outfide corner post, and five with each of the others, and let their pofition be fuch as to cover the infide of the post, so that when feen from between the rows the lower part of each post shall be concealed from the view, and present the appearance of a bundle of rods (fig 1.)

Things being thus disposed, the skeleton of a thatched roof may be formed by means of the loofe ends of the rods. A rod from one of the posts being so bent as to meet a fimilar one from the post immediately opposite to it, in the middle of the space between them, let the two rods be made to cross each other, and let them be bound together at their croffing (fig. 2.), and we shall have the exact form of the Gothic arch. The same being done with each pair of opposite posts, and a fet of pointed arches being formed, let them be connected together by means of a straight pole laid upon the forks of the croffing rods, and bound to each of them, as in fig. 3: then let a loofe rod be brought from each of any two contiguous posts in the same row, so as to form a pointed arch, fimilar to that just described, and nearly of the same height. This being done with every two contiguous posts (fig. 4.), and a new set of pointed arches being thus produced, standing opposite to each other in pairs, let each pair be bound by a horizontal pole lying on the opposite forks, and croffing the longitudinal pole described above.

"Two of the rods of each corner post, and three of those of each of the others. being thus disposed of, we have one of each corner post and two of each middle post still to employ, which is done as follows: A pair of these unoccupied rods being brought from any two posts which stand diagonally to each other, and made to meet in the middle, not as in the first case croffing in an angle, but fide by fide, forming a femicircle, and joined together after the manner of a hoop; and the same being done with every pair of diagonal posts (fig.

5.), the whole rods will have been employed.

"In this manuer a frame would be constructed fit to support thatch or other covering; and such a one has probably been often used. It would feem, however, that, for the take of strength, the number of rods has been increased in each cluster, by the introduction, between every two of them, of an additional rod, which rifing with them to the roof, still continues its middle position, as they spread asunder, and meets the b zontal pole at an intermediate point. This is shown in fig. 6. which is drawn with its covering of thatch; and, from the imitation of a dwelling fo conftructed, we may eafily trace the three leading characteristics of Gothic architecture, the pointed arch, the clustered column, and the branching roof, as exhibited in fig. 7."

Upon the same principles Sir Jams Hall, with much ingenuity, accounts for the peculiar forms of the Gothic door, the Gothic window, and the pointed spire: but it is not our intention to superfede the necessity of having recourse to his memoir, but to excite the defire

Plate V.

Architec- of our readers to perufe as well that paper as a larger work which he promifes on the fame subject, and in which Arithmetic, we doubt not but they will find both entertainment and instruction. We shall conclude this article, therefore, with an experimental proof of the justness of his hypo-

In the greater part of our late attempts at Gothic architecture, it is allowed by every man of talke that we have failed. The failure is to be accounted for by the buildings having been conftructed upon no confiftent principle, applicable to every part of them, but upon a fervile copying of ancient edifices, of which the structure was little understood by the copiers. Sir James Hall, however, by applying his theory to practice, has conftructed a building in this ftyle, which has far furpuffed, he fays, his own expectation, and has certainly gained the approbation of every man of tafte and science by whom we have had occasion to hear it mentioned. "A fet of posts of ask, about three inches in diameter, were placed in two rows, four feet afunder, and at the interval of four feet in the rows; then a number of slender and tapering willow rods, ten feet in length, were applied to the posts, and, in the manner which we have described, formed into a frame, which being covered with thatch, produced a very substantial roof, under which a person can walk with eafe.

"This little structure exhibits, in miniature, all the characteristic features of the Gothic style. It is in the form of a cross, with a nave, a choir, and a north and fouth transept. The thatch, being so disposed on the frame as not to hide the rods of which it is composed, they represent accurately the pointed and semicircular arches, and all the other peculiarities of a groined roof."

ARCTUS, a name given by the Greeks to two constellations of the northern hemisphere, by the Latins called URSA Major and Minor, and by us the Greater and Leffer BEAR.

BINARY ARITHMETIC. See BINARY Arithmetic, Encycl.

Duodecimal ARITHMETIC, is that which proceeds from 12 to 12, or by a continual fubdivision according to 12. This is greatly used by most artificers in calculating the quantity of their work; as bricklayers, carpenters, painters, tilers, &c.

Harmonical ARITHMETIC, is so much of the doctrine of numbers as relates to the making the comparisons,

reductions, &c. of musical intervals.

ARITHMETIC of Infinites, is the method of fumming up a feries of numbers, of which the number of terms is infinite. This method was first invented by Dr Wallis, as appears by his treatife on that subject; where he shows its uses in geometry, in finding the areas of Inperficies, the contents of solids, &c. But the method of fluxions, which is a kind of universal arithmetic of infinites, performs all these more easily, as well as a great many other things, which the former will not

Logistical ARITHMETIC, a name fometimes employed for the arithmetic of lexagelimal fractions, used in akronomical computations. Shakerly, in his Tabula Britannica, has a table of logarithms adapted to sexagesimal fractions, which he calls logistical logarithms; and the expeditious arithmetic, obtained by means of them, he calls logifical arithmetic. The term logifical arith-SUPPL. VOL. I. Part I.

metic, however, or logisties, has been used by Vieta and Arithmetic others for the rules of computations in algebra.

Political ARITHMETIC. See POLITICAL Arithmetic,

Sexagefimal ARITHMETIC. See ARITHMETIC (Hift.) Encycl.

Tetradic ARITHMETIC, is that in which only the four characters 0, 1, 2, 3, are used. A treatise of this kind of arithmetic is extant by Erhard or Echard Weigel. But both this and binary arithmetic are little better than curiofities, especially with regard to practice; as all numbers are much more compendiously and conveniently expressed by the common decuple scale.

Universal ARITHMETIC, is the name given by Newton to the science of algebra; of which he lest at Cambridge an excellent treatife, being the text-book drawn up for the use of his lectures, while he was professor of

mathematics in that university.

ARITHMETICAL COMPLEMENT, of a logarithm, is what the logarithm wants of 10.00000, &c. and the easiest way to find it is, beginning at the left hand, to subtract every figure from 9, and the last

ARTEDI (John), was born in the year 1705, in the province of Angermania, in Sweden. From nature he inherited an ardent passion for all branches of natural history, but he excelled most in that branch of it which is termed ichihyology. In 1724 he went to study at the university of Upfal, where some years afterwards he gained the friendship of the immortal Linnæus, who narrates the principal events of his life in the fol-

lowing animated terms.

"In 1728 (fays Linnæus) I came from Lund to Upfal. I wished to devote myself to medicine. I inquired who, at that univerfity, excelled most for his knowledge: every one named Artedi. I was impatient to fee him. I found him pale, and in great distress for the loss of his father, with his thin hair neglected. He refembled the portrait of Ray the naturalist. His judgment was ripe, his thoughts profound, his manners fimple, his virtues antique. The converfation turned upon stones, plants, animals. I was enchanted with his observations, equally ingenious and new; for at the very first he was not afraid to communicate them to me with the utmost frankness. I defired his friendship, he asked mine. From that moment we formed a friendship; which we cultivated with the greatest ardour for seven months at Upsal. I was his best friend, and I never had any who was more dear to me. How fweet was that intimacy! With what pleasure did we fee it increase from day to day! The difference, even of our characters, was useful to us. His mind was more fevere, more attentive; he observed more slowly, and with greater care. A noble emulation animated us. As I despaired of ever becoming as well instructed in chemistry as he, I abandoned it; he also ceased to study botany with the same ardour, to which I had devoted myself in a particular manner. We continued thus to fludy different branches of science; and when one of us excelled the other, he acknowledged him for his master. We disputed the palm in ichthyology; but foon I was forced to yield, and I abandoned that part of natural history to him, as well as the amphibia. I fucceeded better than he in the knowledge of birds and

Object of

es. We marched together as equals in lithology, and the history of quadrupeds. When one of us made an observation, he communicated it to the other: scarce a day passed in which one did not learn from the other some new and interesting particular. Thus emulation excited our industry, and mutual assistance aided our efforts. In foite of the distance of our lodgings, we saw each other every day. At last I set out for Lapland; he went to London. He bequeathed to me his manuferipts and his books.

" In 1735 I went to Leyden, where I found Artedi. I recounted my adventures; he communicated his to me. He was not rich, and therefore was unable to be at the expence of taking his degrees in physicrecommended him to Seba, who engaged him to publish his work on fishes. Artedi went to join him at Am-

" Scarcely had I finished my Fundamenta Botanica. I communicated it to him; he let me fee his Philosophia Ichthyologica He proposed to finish as quickly as posfible the work of Seba, and to put the last hand to it. He showed me all his manuscripts which I had not seen: I was pressed in point of time, and began to be impatient as being detained fo long. Alas! if I had known this was the last time I should see him, how should I have prolonged it!

" Some days after, as he returned to fup with Seba, the night being dark, he fell into the canal. Nobody perceived it, and he perished. Thus died, by water,

Artedi. insects, and he no longer tried to excel in these branch- this great ichthyologist, who had ever delighted in that Artedi. element."

Of the works of this eminent naturalist there have been two editions, of which the former was published by Linnœus in 1738, and the latter by Dr Walbaum of Lubeck, in the years 1788, 1789, and 1792. This edition, which is by much the most valuable, is in three volumes 4to; of which the first contains the history of the science of ichthyology, commencing several years before the Christian era, and coming down to the prefent times. The second presents to the reader the Philosophia Ichthyologica of Artedi, improved by Walbaum, who was benefited by the writings of Monro, Camper, Kætseuter, and others. Here also are added tables containing the system of fishes by Ray, Dale, Schaeffir, Linnæus, Gowan, Scopola, Klein, and Gro-The third volume, which completes the collection of Artedi's works, contains the technical definitions of the science. After the generic and individual characters, come the names and Latin phrases of Artedi; the fynonymes of the best naturalists; the vulgar names in English, German, Swedish, Ruslian, Danish, Norwegian, Dutch, and Samoyed; the feafon and the countries where every kind is found, their varieties, their description, and observations. The modern discoveries, even to our own times, are added; fo that in this part is collected the observations of Gronovius, Brunich, Penant, Forster, Klein, Bloch, Gmelin, Haffelquist, Broussonet, Leske, Buish, Linnæus, and other great examiners of nature.

TR

lieft ages, and is converfant about the most sublime objects of inquiry which can employ the mind of man. It has accordingly been treated at great length in the Encyclopædia Britannica; but, in the opinion of some of the most judicious readers of that work, the compiler of the fystem which is there delivered has failed in his attempt to give a perspicuous and connected view of the science in its present state of improvement. This defect it is our duty to remedy. Our object, therefore, in this this article. Supplementary article, will be to bring into one point of view the physical science which may be derived from the confideration of the celestial motions; that is, to deduce from the general laws of those motions the inferences with respect to their supposed causes, which constitute the philosophy of the astronomer.

The causes of all phenomena are not only inferred from the phenomena, but are characterised by them: and we can form no notion of their nature but what we conceive as competent to the phenomena themselves. The astronomical phenomena are assumed to be the motions of the bodies, which we call the fun, the planets, the comets, &c. The notion which we express by the word body in the present case, is supposed to be the same with that which we form of other objects around us, to which we give the same name; such as stones, sticks, the bodies of animals, &c. Therefore the notion which we have of the causes of the celestial motions must be the

TS a science which has been cultivated from the ear- in those more familiar bodies. All men seem to have Metaphori agreed in giving the name FORCES, or MOVING FORCES, cal use of to the causes of those familiar motions. This is a fi-the term gurative or metaphorical term. The true and original force. meaning of it is, the exertion which we are conscious of making when we ourselves put other bodies in motion. Force, when used without figure, always fignifies the exertion of a living and acting thing. We are more interested in those productions of motion than in any other, and our recollections of them are more numerous. Hence it has happened that we use the same term to express the cause of bodily motion in general, and say that a magnet has force, that a spring has force, that a moving body has force.

Our own force is always exerted by the intervention of our own body; and we find that the fame exertion by which we move a stone, enables us to move another man; therefore we conceive his body to refemble a stone in this respect, and that it also requires the exertion of force to put it in motion. But when we reflect on our employment of force for producing motion in a. body, we find ourselves puzzled how to account for the motion of our own bodies. Here we perceive no intervening exertion but that of willing to do it; yet we find that we cannot move it as we please. We also find that a greater motion requires a greater exertion. It is therefore to this exertion that the reflecting man restrains the term force; and he acknowledges that every same with that which we have of the causes of motion other use of it is metaphorical, and that it is a resem-

blance

blance in the ultimate effect alone which disposes us to employ the term in fuch cases: but we find no great inconvenience in the want of another term.

We farther find, that our exertion is necessary, not only for producing motion where there was none before, but also for producing any change of motion; and accurate observation shows us, that the same force is required for changing a motion by any given quantity, as for producing that quantity where there was none before.

Lastly, we are conscious of exerting force when we refift the exerted force of another; and that an exertion, perfectly fimilar to this, will prevent fome very familiar tendencies to motion in the bodies around us: thus an exertion is necessary for carrying a weight, that is, for

preventing the fall of that weight.

All their resemblances between the effects of our forcible exertions and the changes of motion which accompany the meeting, and fometimes the mere vicinity of other bodies, justify us in the use of this figurative language. The refemblance is found to be the more perfect as we observe it with more care, and, in short, appears to be without exception. Bodies are therefore faid to all on each other, to refift each other, to refift a change of motion, &c.

Therefore, wherever we observe a change of motion, we infer the existence and exertion of a changing force; and we infer the direction of that exertion from the direction of the change; and the quantity of the exertion, or intenfity of the force, from the quantity of the

change.

The study of the causes of the celestial motions is therefore hardly different from the study of the motions themselves; fince the agency, the kind, and the degree of the moving force, are immediate inferences from the existence, the kind, and the quantity of the change of

Our notion of a moving power is that of a power Dur notion of a moving which produces motion, that is, a fuccessive change of place. Continuation of the motion produced is therefore involved in the very notion of the production of motion; therefore the continued agency of the moving power, or of any power, is not necessary for the continuation of the motion. Motion is confidered as a state or condition of the body; there is not any exertion of power therefore in the continuation of motion: But every change is indicative of a changing cause; and when the change is the fame, in all its circumstances, the cause is necessarily conceived to be the same or equal.

The condition of a body, in respect of motion, can differ from that of another equal body only in its direction and in its velocity. If the directions are the fame, the difference of conditions can only be in the difference of velocity. One body has a determination, by which it would describe ten feet uniformly in a fecond, if nothing changed this determination; the other has a determination, by which it would describe twenty leafure of feet in a fecond. Each of these determinations are supposed to be the effects of forces acting fimilarly in every respect. Therefore these determinations are the only measures of these two forces; that is, moving forces are conceived by us as having the proportion of the velocities which they produce in a body by acting in a manner perfectly similar.

We can conceive a force acting equally or unequally. If we suppose it to act equally or uniformly, we suppole that in equal times it produces equal effects; that is, equal determinations, or equal changes of determination. We have no other notion of equality or unitormity of action. Therefore it must produce equal augmentations or diminutions of velocity in equal times; therefore it must produce an uniformly accelerated or retarded motion. Uniformly accelerated or retarded mo-Acceleration is, therefore, the mark of uniform or unvaried ac- ed motion tion. In such a motion, the changes of velocity are the mark of proportional to the times from the beginning of the actaclin; tion; and if the motion has begun from rest, the whole acquired velocities are proportional to the times from the beginning of the motion In this case, the spaces described are as the squares of the times from the beginning of the motion; and thus we arrive at an oftenfible mark of the unvaried action of a moving force. viz. spaces increasing in the duplicate ratio of the times: for space and time are all that we can immediately obferve in any motion that is continually varying; the velocity or determination is only an inference, on the fupposition that the motion continues unchanged for

some time, or that all action ceales for some time. This abstract reasoning is perfectly agreeable to every phenomenon that we can observe with distinctness. Thus we cannot, or at least we do not, conceive the weight of a body to vary its action during the fall. We confider this weight as the cause of the fall—as the moving force - and we conceive it to act uniformly. And, in tact, a body falling freely, describes spaces which are proportional, not to the times, but to the fquares of the times, and the fall is a motion uniformly accelerated. In like manner, the motion of a body rifing in the air, in opposition to gravity, is uniformly retarded.

This kind of motion also gives us a certain measure And gives of the acquired velocity, although there is not, in fact, a measure any space observed to be uniformly described during of the acany time whatever. In this motion we know that the locity. final determination, produced by the accumulated or continued action of the unvaried force, is such that the body would describe uniformly twice the space which it has described with the accelerated motion.

And it is by this method that we obtain the simplest measure of any moving force, and can compare it with another. If we observe that by the action of one sorce (known to be uniform by the spaces being proportional to the squares of the times) ten reet have been described in a second, and that by the unitorm action of another force eighty feet are described in two seconds. we know that the last force is double of the first : for in the second motion, 80 feet were described in two seconds, and therefore 20 feet of this were described in the first second (because the motion is uniformly accelerated); and at the end of a second, the first body had a determination by which it would describe 20 feet uniformly in a fecond; and the fecond body had acquired a determination by which it would have defcribed 40 feet unitormly in the next fecond, had not the moving force continued to act on it, and made it really describe 60 feet with an accelerated motion.

Because halves have the same proportions with the units of which they are the halves, it is plain that we may take the spaces, described in equal times with mo-

noving

tions uniformly accelerated, as measures of the forces which have produced those motions. The velocities

generated are, however, the best measures.

When the actions of forces are not uniform, it is Measure of the velocity more difficult to learn what is the measure of the velocity produced by their accumulated action. But it can by action be determined with equal accuracy; that is, we can denot unitermine what is the velocity which would have been proform duced by the uniform action of the force during the fame time, and therefore we obtain a measure of the force. Mathematicians are farther able to demonstrate, that if forces vary their continued action in any manner whatever, the proportion of the spaces described by two bodies in equal times approaches nearer and nearer to the proportion of the spaces which they would describe in those times by the uniform action of the forces, as the

times themselves are smaller; and therefore whenever we can point out the ultimate ratio of the spaces deferibed in equal times, these times being diminished

without end, we obtain the ratio of the forces.

Motions may be changed, not only in quantity, by acceleration or retardation, but also in direction, by deflecting a body from its former direction. When a Plate VI. body, moving uniformly in the direction AB (fig. 1.), has its motion changed in the point B, and, instead of describing BC uniformly in the next moment with the former velocity, describes BD uniformly in that moment, it is plain that the motion BD will be the same, whether the body had begun to move in A, or in F, or in G, or in B, provided only that its determination to move, or its velocity, be the same in all those points. Complete the parallelogram BCDE. It is well known, that if one force act on the body which would make it describe BC, and another which would make it describe BE, the body will describe BD. Hence we learn, that when a body has the motion BC changed into the motion BD, it has been acted on in the point B by a force which would have caused a body at rest in B to describe BE. Thus we can discover the intensity and direction of the transverse force which produces any deflection from the former direction. In general, the force is that which would have produced in a body at rest that motion BE, which, when compounded with the former motion BC, produces the new motion BD.

These two principles, viz. 1st, that forces are proportional to the velocities which they produce in the same circumstances, and, 2d, the composition of motion or forces, will ferve for all the physical investigations in aftronomy. All the celeftial motions are curvilineal, and therefore are instances of continual deflection, and of the continual action of transverse or deflecting forces. We must therefore endeavour to obtain a general measure of fuch continual deflecting forces.

Let two bodies A and a (fig. 2.) describe in the same Meafure of these forces time the arches AC, ac of two circles. They are deflected from the tangents AB, ab. Let us suppose that the direction of the deflecting forces is known to be that of the chords AE, ae of these circles. Let these be called the DEFLECTIVE CHORDS. Draw CB, cb, parallel to AE, ae, and CD, ed parallel to AB, ab. Join AC, ac, CE, and ce. It is plain that the angle BAC is equal to the angle CEA in the alternate fegment. Therefore ACD is also equal to it; and, because the angle CAD is common to the two triangles CAD and EAC, these two triangles are fimilar, and

AD: AC = AC: AE, and AD = $\frac{AC^3}{AE}$. For fimilar reasons $ad = \frac{ac^2}{ae}$. But AD and ad are respectively equal to BC and bc. Therefore BC = $\frac{AC^2}{AE}$, and $bc = \frac{ac^2}{ae}$. Therefore BC: $bc = \frac{AC^2}{AE}$: $\frac{ac^2}{ae}$, or BC: bc = AC2 x ae: ac2 x AE. But BC and bc being respectively equal to AD and ad, are equal to the spaces through which the deflecting forces would have impelled the bodies from a state of rest in the time of describing the arches AC, ac. Therefore, when thele times are diminished without end, the ultimate ratio of AD and ad is the ratio of the forces which deflect the bodies in the points A and a. But it is evident that the ultimate ratio of AC to ac is the ratio of the velocity in the point A to the velocity in the point a; because these arches are supposed to be described in the same or equal times. Therefore the deflecting forces, by which bodies are made to describe arches of circles, are to each other as the squares of the velocities directly, and as the deflective cords of those circles inversely. This ratio may be expressed. F: $f = \frac{V^2}{C} : \frac{v^2}{c}$; or thus, in a proportional equation,

It is easy to see that in this last formula f expresses directly the line bc, or the space through which the body is actually made to deviate from rectilineal motion in the time of defcribing the arch ac. It is a third proportional to ae the deflective chord, and ac the arch of the circumference described in a small moment of time. This is the measure afforded immediately by obfervation. We have observed the arch AC that is described, and know the direction and the length of AE from some circumstances of the case. The formula which comes to us, when treating this question by the help of

fluxions, is $f = \frac{2 v^2}{c}$. This is perhaps a more proper expression of the physical fact; for it expresses twice the line bc, or the measure of the velocity which the deflecting force would have generated in the body by acting on it during the time of its describing the arch ac. But it is indifferent which measure we take, provided we always take the same measure. The first mathematicians, however, have committed mistakes by mix-

ing them.

The planets, however, do not describe circles: but all the curves which can be described by the action of finite deflecting forces are of fuch a nature, that we can describe a circle through any point, having the same tangent, and the fame curvature which the planetary curve has in that point, and which therefore ultimately coalesces with it. This being the case, it is plain that the planet, while passing through a point of the curve, and describing an indefinitely small arch of it, is in the fame condition as if describing the coincident arch of the equicurve circle. Hence we obtain this most general proposition, that the transverse force by which a planet is made to describe any curve, is directly as the square of its velocity, and inversely as the deflective chord of the equicurve circle.

Farther: The velocity of a body in any point A

S Intensity tion of deflecting forces.

obtained.

(fig. 2.) of the curve, is equal to that which the deflec- minute deviations which must result from the physical tive force in that point would generate in the body by acting uniformly on it along AF, one-fourth part of the deflective cord AE or the equicurve circle. It is the same which the body would acquire at F, after a

uni ormly accelerated motion along AF.

For it is certain that there is some length AF, such that the velocity acquired at F is the same with the velocity in the point A of the curve. Draw FG parallel to the tangent, and join AG. Make the arch ACI = 2 AF. Then, because the space described with a uniformly accelerated motion is one half of the space which would be uniformly described with the final velocity, the arch ACI would be uniformly described with the velocity which the body has at A in the time that AF is described with the uniformly accelerated motion; and the arch AB will be to the arch AI as the time of describing AB to that of describing AI; that is, as the time of falling through AD to that of falling through AF. But the motion along AF being uniformly accelerated, the spaces are as the squares of the times. Therefore AD is to AF as the square of the arch AC to the square of the arch AI. But AD is to AF as the square of the chord AC is to the square of the chord AG. Therefore the arch AC is to the chord AC as the arch AI is to the chord AG. But the arch and chord AC are ultimately in the ratio of equality. Therefore the chord AG is equal to the arch AI. Therefore AG is double of AF. But because the triangles FAG and GAE are fimilar, AF is to AG as AG to AE; and therefore AE is double of AG and quadruple of AF. Therefore the velocity at A in the curve is that which would be produced by the uniform impulse of the deflecting force along the fourth part of the deflective chord of the equicurve circle.

These two affections or properties of curvilineal moaffections of tions are of the most extensive use, and give an easier solution of most questions than we obtain by the more usual methods, and deserve to be kept in remembrance by fuch as engage much in the discussion of questions

of this kind.

Thus the investigation of the forces which regulate the planetary motions, is reduced to the talk of discovering the velocity of the planet in the different points of its orbit, and the curvature in those points, and the

position of the deflective chords.

The physical science of astronomy must consist in the discovery of the general laws which can be affirmed with respect to the exertion of those forces, whether with reevery motion that is observed is an immediate or remote confequence of those general laws, he will have completed the science, and explained every appearance.

This has accordingly been done by Sir Isaac Newton and his followers. Sir Isaac Newton has discovered the general laws which regulate the exertions of those forces which produce the planetary motions, by reasoning from general phenomena which had been observed with a cercertain confiderable deviations from the generality which be supposed to be perfect were necessary consequences of the very universality of the physical law, although the planets were retained in their orbits by a force contiphenomenon was not so general as was at full imagined. He has gone farther, and has pointed out some other of motion was also observed by the secondary planets

law, but which the art of observation was not then sufficiently advanced to discover in the phenomena. This excited the efforts of men of science to improve the art of astronomical observation; and not only have the inti- His followmations of Newton been verified by modern observation, ers. but other deviations have been discovered, and, in process of time, have also been shown to be consequences of the same general law of agency: And, at this prefent day, there is not a fingle anomaly of the planetary motions which has not been shown to be a modification of one general law which regulates the action; and therefore characterifes the nature of that fingle force which actuates the whole fystem of the fun, and his at-

tending planets and comets.

It was a most fortunate circumstance that the constitution of the folar fystem was fuch that the deviations from the general law are not very confiderable. The cafe might have been far otherwise, although the law, or nature of the planetary force, were the fame, and the fystem had been equally harmonious and beautiful. Had two or three of the planets been vally larger than they are, it would have been extremely difficult to difcover any laws of their motion sufficiently general to have led to the suspicion or the discovery of the univerfal law of action, or the specific circumstance in the planetary force which distinguishes it from all others, and characterises its nature. But the three laws of the planetary motions discovered by Kepler were so nearly true, at least with respect to the primary planets, that the deviations could not be observed, and they were thought to be exact. It was on the supposition that they were exact, that Newton affirmed that they were only modifications of one law still more general, nay universal.

We shall follow in order the steps of this investiga-

Sir Isaac Newton took it for granted, that the sun The steps and planets confifted of matter which refembled thoseby which bodies which we daily handle, at least in respect of they protheir mobility; and that the forces which agitate ceeded. them, confidered merely as moving forces, but without considering or attending to their mode of operation, were to be inferred, both as to their direction and as to their intensity, from the changes of motion which were ascribed to their agency. He first endeavoured to discover the direction of that transverse force by which the planets are made to describe curve lines. Kepler's first law furnished him with ample means for fpect to their direction or the intensity of their action. this discovery. Kepler had discovered, that the right If the mechanician can do more than this, and show that line joining the fun and any planet described areas proportional to the times. Newton demonstrated, that if a body was fo carried round a fixed point fitnated in the plane of its motion, that the right line joining it with that point described areas proportional to the times, the force which deflected it from an uniform rectilineal motion was continually directed to that fixed point. This makes the 2d proposition of his immortal work The Mathematical Principles of Natural Philosophy, and tain precision before his time; and has also shown that it is given in the article ASTRONOMY of the Encyclopædia Britannica, § 260.

Hence Sir Isaac Newton inferred, that the primary nually directed to the fun; and, because Kepler's law

curvilineal motions.

Physical cience of aftronomy

Completed by Newton in their revolutions round their respective primary planets, this inference was extended to them.

Centriperal forces.

From the circumstance that the planetary deflecting forces in the different points of the orbit are always directed toward one point as to a centre, they have been called CENTRIPETAL FORCES.

16 Velocity of

Law of

From this proposition may be deduced a corollary a planet in which establishes a general law of the motion of any rest points planet in the different parts of its orbit, namely, that of its orbit. the velocity which a planet has in the different points of its path are inversely proportional to the perpendiculars drawn from the fun on the tangents to the orbit in those points respectively. For, let AB, ab (fig. 3.) be two arches (extremely small), described in equal times, these arches must be ultimately proportional to the velocities with which they are described. Let SP, Sp he perpendicular to the tangents AP, ap. The triangles ASB, aSb are equal, becanfe equal areas are described by the radii vectores SA, Sa, in equal times: but in equal triangles, the bases AB, ab, are reciprocally 25 their heights SP, Sp, or AB: ab = Sp : SP.

This corollary gives us another expression of the ratio of the centripetal forces in different points A and a of a curve. We faw by a former proposition, that the force at A (fig. 2.) is to the force at a as AC2 × ae to $ac^2 \times AE$, which we may express thus: $F: f = V^2$ $\times c: v^2 \times C$ If we express the perpendiculars SP, Sp (in fig. 3.) by the fymbols P, p, we have $V^2: v^2 = p^2: P^2$, and therefore $F: f = p^2 \times c: P^2 \times C$. The centripetal forces in different points of an orbit are in the ratio compounded of the inverse duplicate ratio of the perpendiculars drawn to the tangents in those points from the centre of forces, and the inverse ratio of the deslective chords of the

equicurve circles.

We are now in a condition to determine the law of action of the centripetal force by which a planet is rethe centri tained in its orbit round the fun, or the relation which petal force, subfifts between the intensity of its action and the distance of the planet from the sun: for we know the elliptical figure of the orbit, and we can draw a tangent to it in any point, and a perpendicular from the fun to

Kepler's fecond law or observation of the planetary motions was, that each primary planet described an ellipse, having the fun in one focus. It is easy to show, even without any knowledge of the geometrical properties of the ellipse, what is the proportion of the intensities of the deflecting force at the aphelion and perihelion (fee fig. 4.) At those two points of the orbit, the motion of the planet is at right angles to the line joining it with the fun. Theretore, fince the areas described in equal times are equal, the arches described in equal times must be inversely at the distances from the sun; or the velocities must be inversely as the distances from the fun. But the curvature in the aphelion and perihelion is the same; and therefore the diameters of the equicurve circles in those points are equal. But those diameters are, in this particular case, what we called the deflective chords. Therefore, calling the aphelion and perihelion distances D and d, the velocities in the aphelion and perihelion V and v, let the common deflective chord be C. Then we have $F: f = V^2 \times C: v^2 \times C$, $= V^2 : v^2, = d^2 : D^2$. That is, the forces which deflect the planet in the aphelion and perihelion are in the centripetal forces are inversely proportional to SP2, verfely as the squares of the distances from the sun. A or to the squares of the distances from the sun.

person almost ignorant of mathematics may see the truth of this by looking into a table of natural versed fines. He will observe, that the versed fine of one degree is quadruple the verfed fine of half a degree, and fixteen times the versed sine of a quarter of a degree; in short, that the versed sines of small arches are in the proportion of the squares of the arches. Now fince the arches described in equal times are inversely as the distances, their versed fines are inversely as the squares of the distances. But these versed fines are the spaces through which the centripetal forces at the aphelion and perihelion deflect the planet from the tangent. Therefore, &c.

Thus we have found, that in the aphelion and perihelion the centripetal force acts with an intensity that is proportional to the squares of the distances inversely. As these are the extreme situations of a planet, and as the proportion of the aphelion and perihelion distances are confiderably different in the different planets, and yet this law of action is observed in them all, it is reafonable to imagine that it holds true, not in those situations only, but in every intermediate fituation. But a conjecture, however probable, is not fufficient, when we aim at accurate science, and it is necessary to examine whether this law of action is really observed in every point of the elliptical orbit.

For this purpose it is necessary to mention some geo-Dem instra-metrical properties of the ellipse. Therefore let ADBE ted with re-(fig. 4.) be the elliptical orbit of a planet or comet, spect to the having the fun in the focus S. Let AB be the transverse axis, and DE the conjugate axis, and C the centre. Let P be any point of the ellipfe. Draw PS through the focus. Draw the tangent PN, and SN from the focus, perpendicular to PN. Draw PQ perpendicular to PN, meeting the transverse axis in Q. Draw QO parallel to PN, meeting PS in O. Alfo draw QR per-

pendicular to PS. Bifect PO in T.

It is demonstrated in the treatifes of conic sections, that PO is one half of the chord of the equicurve or ofculating circle drawn through the point P. Therefore PO is one half of the deflective chord of the planetary orbit. It is also demonstrated, that PR is one half of the parameter or latus rectum of the transverse axis AB. or that it is the third proportional to AC and DC. Therefore PR or Dr is of the same constant magnitude, in whatever part of the circumference the point P is taken.

It is evident that the triangles NSP, RPQ, and QPO, are all similar, by reason of the parallels PN, QO, and the right angles SNP, PRQ, PQO. Therefore we have PR: PQ = PQ: PO. Therefore PR: PO = PR²: PQ², = SN²: SP². Therefore PR × SP² = PO × SN². But the latus redum L is equal to twice PR, and the deflective chord C is equal to twice PO. Therefore $L \times SP^2 = C \times SN^2$. But we have feen, that when a curve is described by means of a centripetal force, fo that areas are described proportional to the times, and therefore the velocities are reciprocally proportional to the perpendiculars drawn from the centre of forces to the tangents, the forces are inversely proportional to C x SN2. 'Therefore, in the elliptical motion of the planets, the forces are inverfely proportional to L × SP2; and fince L is a conftant quantity,

Thus

planet, the centripetal force which continually deflects it from the tangent to its orbit diminishes in the inverse duplicate ratio of the distance from the sun. The same Observe lin he motion thing is observed to be very nearly true in the moon's of the moon motion round the earth, and in the motion of fuch fatellites of Jupiter and Saturn as describe orbits which are fenfibly elliptical. It is also observed in the motion of the comets, at least in that which appeared in 1682 and

It was therefore very natural for Sir Isaac Newton to examine whether the like diminution of force obtained in the action of this force on different planets; that is, whether the deflection of the earth from the tangent of its orbit was to the fimultaneous deflection of Jupiter as the square of Jupiter's distance from the son to the fquare of the earth's diffance. This was very probable, but by no means certain. Its probability is very great indeed, when we know that a comet moves fo in its orbit that its deflections in equal times are inverfely as the squares of its distances from the sun, and that the comet passes through the orbits of all the planets; and when at the same distance from the sun as any one of them, it suffers the same deflection with it. Newton therefore calculated the actual fimultaneous deflections of the different planets, and found them agreeable to this law. But it was desirable to obtain a demonstration of this important proposition in general terms. This nonftrated was supplied by Kepler's third general observation of the motions, viz. that the squares of the periodic times of the different planets were proportional to the cubes of their mean distances from the fun. The orbits of the planets are to nearly circular, that we may suppose them exactly so in the present question, without any remarkable error. In this case, then, the deslective chords are the diameters of the orbits (for DS is equal to AC), and are proportional to the distances, which are their halves. The centripetal forces, being proportional to $\frac{v^2}{c}$, are proportional to $\frac{v^2}{d}$, when d is the radius of the orbit, or the mean distance from the fun. But the velocity in a circular orbit is as the circumference directly, and as the time of a revolution inversely. Therefore, instead of v^2 , we may write $\frac{d^3}{t^3}$, and then the forces will be proportional to $\frac{d^2}{t^2d}$, or to $\frac{d}{t^3}$; that is, directly as the distances, and inversely as the squares of the times of revolution. But, by Kepler's observation, to is proportional to ds. Therefore the centripetal forces are pro-

> squares of the mean distances from the sun. But fince the orbits of the planets are not accurate circles. this determination is but an approximation to the truth, and therefore infusficient for the foundation of so important a proposition; at any rate, it will not apply to the comets, whose orbits are very far from being circular. We must obtain a more accurate demonfiration.

portional to $\frac{d}{d^3}$, or to $\frac{1}{d^2}$; that is, inversely as the

Therefore draw SD (fig. 4.) to the extremity of the conjugate axis, and bisect it in t. About S, with the radius SD, describe the circle DFG. Let Dd, D be equal small arches of the ellipse and the circle. Join

Thus it appears that, with respect to any individual dS, &S. It is well known that DS is half of the chord of the equicurve circle at D, and therefore Dt is one fourth part of it. It has been demonstrated, that the velocity in any point D of a curve, described by means of a deflecting force, is that which the force in that point would communicate to it by uniformly impelling it along the fourth part of the deflective chord, that is, along Dt. But if a body revolved round S in a circle DFG, its velocity in that circle would be that which the deflecting force would communicate to it by uniformly impelling it along one-fourth of the diameter, that is, along Dt. Therefore the planet, if projected in the direction Ds, with the velocity which it has in the point D of the ellipse, would describe the circle DFG by the action of the centripetal force. Farther, it would describe it in the same time that it describes the ellipse; for because the velocities are equal, the areas DSd, DSs are described in the same time. But the bases Dd, Ds being equal, these areas are as their heights Sn (or CD), and SD (or CA). But because the diameter of the circle is equal to AB, the area of the whole ellipse is to the area of the circle as CD is to CA; that is, as the area DSd to the area DSd deferibed in the same time. Therefore the elliptical and circular areas are fimilar portions of the ellipse and circle; and therefore the times of describing them are fimilar portions of the whole revolutions in the ellipse and in the circle. Therefore these revolutions are performed in equal times.

> And thus it follows, that if all the planets and comets were projected, when at their mean distances from the fun, perpendicularly to the radii vectores, they would describe circles round the sun, and the squares of their periodic times would be proportional to the cubes of their mean distances from the fun, as Kepler has obferved; and therefore the centripetal forces would be inversely as the squares of their distances from the fun.

They are not different forces therefore which retain the All the place different planets in their respective orbits, but one force, ets retainacting by the same law upon them all. We may either ed in their conceive it as an attractive force, exerted by the fun, or espective as a tendency in each planet; nay, nothing hinders us one and the from conceiving it as a force external, both to fun and same force. planets, impelling them towards the fun. It may be the impulse of a stream of sluid moving continually toward the son. Sir Isaac Newton did not concern himfelf with this question, but contented himself with the discovery of the law according to which its action was exerted. The steps of this investigation showed him, that a body, projected in any direction whatever, and with any velocity whatever, and subjected to the action of a force directed to the fnn, and inverfely proportion. al to the square of the distance from the sun, will neceffarily describe a conic section, having the sun in the focus. This will be a parabola, if the velocity of projection be that which the centripetal force in that place would communicate to the body by acting on it uniformly along a line equal to half its distance from the fun. If the velocity be greater than this, the path will be a hyperbola; if the velocity be less than this, the path will be an elliptical orbit, in which the body will revolve for ever round the fun.

The 3d Keplerean law is also observed in the revolutions of the fatellites of Jupiter, Saturn, and the lately

n general

discovered planet; and we must infer from it, that they are retained in their orbits round their respective primary planets, by forces whole intenfity decreales according to the fame law of the distances. Also the elliptical motion of the moon round the earth, shows that the force by which she is retained in her orbit varies in the same proportion of the distances. But when we compare the motion of a fatellite of Jupiter with that of one of the fatellites of the other two planets, we find that the proportion does not hold. We shall find, that, at equal distances from Jupiter and Saturn, the force toward Jupiter is almost thrice as great as the force toward Saturn. We shall also find that the force toward Jupiter is three hundred times greater than the force which retains the moon in its elliptical orbit round

the earth, when acting at the same distance. Since a force directed to the fun, and inverfely as the square of the distance, is thus found to pervade all the planetary orbits, it is highly improbable that it will not affect the fecondary planets alio. The moon accompanies the earth in its motion round the fun. It may appear sufficient for this purpose, that the moon be retained in its orbit by a force directed to the earth. Were the moon connected with the earth by a rope or chain, this would be true; for the earth could get no motion without dragging the moon along with it: but it is quite otherwise with bodies moving in free space, without any material connections. When a body that is moving uniformly in a straight line is accompanied by another which describes around it areas proportional to the times, the force which continually deflects this fatellite is always directed to the moving central body. This is eafily feen; for whatever be the mutual action lites of all of two bodies, and their relative motions in confequence the planets of this action, if the same velocity be impressed at once on both bodies in the same direction, their mutual actions and relative motions will be the fame as they would have been without this common impulse. Thus every thing is done in a ship that is sailing steadily in the same manner as if she were at rest. If therefore the moon be observed to describe areas round the earth, which are precisely proportional to the times, while the earth moves in an orbit round the fun, we must infer that the moon receives, in every instant, an impulse the fame in every respect with what the earth receives at the fame instant; or that the moon is acted on by a force parallel to the earth's distance from the sun, and proportional to the square of that distance inversely. Now this is very nearly true of the lunar motions; and we must infer that the moon is subjected to this solar action, or this tendency to the fun. The same must be affirmed of the fatellites of the other planets.

But a force inverfely proportional to the square of the earth's distance from the sun is not what the univerfality of the law requires: It must be inversely as the square of the moon's distance from the sun: and it must not be parallel to the earth's distance from the sun, but must be directed toward the sun; and therefore, in the quadratures, it must converge to the earth's radius vector. Therefore, fince a force having the above mentioned conditions will allow the description of areas round the arth exactly proportional to the times, a force acting on the moon, inverfely proportional to the iquare of her diffance from the fun, and directed exactly to the fun, is incompatible with the accurate ellipti-

cal motion round the earth. At new moon, her ten- 23 dency to the fun exceeds the earth's tendency to him, regularity and this excess will diminish her tendency to the earth, of the and her motion will be less incurvated, so that the moon's will retire a little from the earth. At full moon, the motion earth's tendency to the fun exceeds the moon's tendency to him, and the earth will separate a little from the moon, so that the relative orbit will again be less incurvated. In the quadratures, the impulse on the moon is indeed equal to that on the earth, but not parallel, and tends to make the moon approach the earth, and increase the curvature of her orbit. In other fituations of the moon, this want of equality and parallelism of the forces acting on the earth and moon, must produce other difturbances of the regular elliptical motion.

Newton faw this at once; and, to his great delight, he faw that the great deviations from regular motion, which had been discovered by Ptolemy and Tycho Brahé, called the Annual Equation, the Variation, and the Evection, were such as most obviously resulted from the regular influence of the fun on the moon. The first deviation from the regular elliptical motion is occasioned by the increase of the sun's disturbing force as the earth approaches the perihelion; and it enlarges the lunar orbit, by diminishing the tendency to the earth, and increases the periodic time. The second arises from the direction of the diffurbing force, by which it accelerates the moon's angular motion in the fecond and fourth quadrants of her orbit, and retards it in the first and third. The last affects the eccentricity of the orbit, by changing the ratio of the whole or compound tendency of the moon to the earth in her perigee and apogee. This fuccess incited him to an accurate examination of the consequences of this influence. It is the boast of May be cal this discovery of the law of the planetary deflections, culated that all its effects may be calculated with the utmost with preprecision. The part of the moon's deflection toward cision. the fun, which is neither equal nor parallel to the simultaneous deflection of the earth, may be separated from the part which is equal and parallel to it, and it may he called the fun's disturbing force. Its proportion to the moon's deflection towards the earth may be accurately alcertained, and its inclination to the line of the moon's motion in every point of her orbit may be pointed out. This being done, the accumulated effect of this disturbing force after any given time, however variable, both in direction and intenfity during this time, may be determined by the 30th and other propositions of the first book of the Mathematical Principles of Natural Philosophy. And thus may the moon's motion, when fo disturbed, be determined and compared with her motion really observed.

All this has been done by Sir Isaac Newton with the most astonishing address and sagacity, fua mathesi facem preferente, partly in the PRINCIPIA, and partly in his LUNE THEORIA. This investigation, whether we confider the complete originality of the whole process, or the ingenuity of the method, or the fagacity in feeing and clearly difcriminating the different circumstances of the question, or the wonderful fertility of resource, or the new and most refined mathematical principles and methods that he employed - must ever be considered as the most brilliant specimen of human invention and reafoning that ever was exhibited to the world.

In this investigation Newton not only determined the quantity,

The fatel. this folar action.

quantity, the period, and the changes of those inequa- ry motions, from the fingle principle, that the defieldlities, which had been fo confiderable and remarkable as to be observed by former astronomers, and this with an exactness far surpassing what could ever be attained by mere observation; but he also pointed out several other periodical inequalities, which were too fmall, and too tnuch implicated with the rest, ever to be discovered or to be separated from them. We do not say that he completed the theory of the lunar motions; but he pointed out the methods of investigation, and he furnished all the means of profecuting it, by giving the world the elements of a new species of mathematics, without which it would have been in vain to attempt it. Both this new mathematics, and the methods of applying it to fuch questions, have been affiduously studied and improved by the great mathematicians of this century; and the lunar theory has been carried to fuch a degree of perfection, that we can compute her place in the heavens for any past age without deviating above one minute of a degree from the actual observation.

There is one empirical equation of the moon's motion which the comparison of ancient and modern eclipfes obliges the astronomers to employ, without being able to deduce it, like the rest, à priori, from the theory of an universal force inversely proportional to the square of the distance. It has therefore been considered as a flumbling block in the Newtonian philosophy. This on of the is what is called the fecular equation of the moon's mean motion. The mean motion is deduced from a comparifon of distant observations. The time between them, being divided by the number of intervening revolutions, gives the average time of one revolution, or the mean lunar period. When the ancient Chaldean observations are compared with those of Hipparchus, we obtain a certain period; when those of Hipparchus are compared with fome in the 9th century, we obtain a period fomewhat shorter; when the last are compared with those of Tycho Brahé, we obtain one still shorter; and when Brahe's are compared with those of our day, we obtain the shortest period of all-and thus the moon's mean motion appears to accelerate continually; and the accelerations appear to be in the duplicate ratio of the times. The acceleration for the century which ended in 1700 is about 9 seconds of a degree; that is to say, the whole motion of the moon during the 17th century must be increased o seconds, in order to obtain its motion during the 18th; and as much must be taken from it, or added to the computed longitude, to obtain its motion during the 16th; and the double of this must be taken from the motion during the 16th, to obtain its motion during the 15th, &c. Or it will be sufficient to calculate the moon's mean longitude for any time past or to come by the secular motion which obtains in the prefent century, and then to add to this longitude the product of 9 feconds, multiplied by the square of the number of centuries which intervene. Thus having found the mean longitude for the year 1200, add 9 feconds, multiplied by 36, for fix centuries. By this method we shall make our calculation agree with the most ancient and all intermediate observations. If we neglect this correction, we shall differ more than a degree from the Chaldean observations of the moon's place in the

The mathematicians having fucceeded fo completely in deducing all the observed inequalities of the planeta-SUPPL. VOL. I. Part I.

ing forces diminished in the inverse duplicate ratio of the diffances, were fretted by this exception, the reality of which they could not contest. Many opinions were formed about its cause. Some have attempted to deduce it from the action of the planets on the moon; others have deduced it from the oblate firm of the earth, and the translation of the ocean by the tides; others have supposed it owing to the resistance of the ether in the celeftial spaces; and others have imagined that the action of the deflecting force requires time for its propagation to a distance: But their deductions have been proved unfatisfactory, and have by no means the precision and evidence that have been attained in the other questions of physical astronomy. At last M. de la Place, of the Royal Academy of Sciences at Paris, has happily fucceeded, and deduced the fecular equation of the moon from the Newtonian law of planetary deflection. It is produced in the following manner. Suppose the moon revolving round the earth, undi-Deduced

flurbed by any deflection toward the fun, and that the from the time of her revolution is exactly afcertained. Now let law of plathe influence of the sun be added. This diminishes her netary detendency to the earth in opposition and conjunction, section. and increases it in the quadratures: but the diminutions exceed the augmentations both in quantity and duration; and the excess is equivalent to Troth of her tendency to the earth. Therefore this diminished tendency cannot retain the moon in the same orbit; she must retire farther from the earth, and describe an orbit which is lefs incurvated by τ^1_{79} th part; and the must employ a longer time in a revolution. The period therefore which we observe, is not that which would have obtained had the moon been influenced by the earth alone. We should not have known that her natural period was increased, had the disturbing influence of the sun remained unchanged; but this varies in the inverse triplicate ratio of the earth's distance from the sun, and is therefore greater in our winter, when the earth is nearer to the fun. This is the fource of the annual equation, by which the lunar period in January is made to exceed that in July nearly 24 minutes. The angular velocity of the moon is diminished in general 770, and this numerical coefficient varies in the inverse ratio of the cube of the earth's distance from the sun. If we expand this inverse cube of the earth's distance into a series arranged according to the fines and cofines of the earth's mean motion, making the earth's mean distance unity, we shall find that the series contains a term equal to } of the square of the eccentricity of the earth's orbit. Therefore the expression of the diminution of the moon's angular velocity contains a term equal to Tro of this velocity, multiplied by \frac{3}{2} of the square of the earth's eccentricity; or equal to the product of the square of the eccentricity, multiplied by the moon's angular velocity, and divided by 119,33 (2 of 179). Did this eccentricity remain constant, this product would also be constant, and would still be confounded with the general diminution, making a constant part of it: but the eccentricity of the earth's orbit is known to diminish, and its diminution is the result of the universality of the Newtonian law of the planetary deflections. Although this diminution is exceedingly small, its effect on the lunar motion becomes fensible by accumulation in the course of ages. The eccentricity diminishing, the dimi-

r equaloon's iean dinution of the moon's angular motion must also diminish, that is, the angular motion must increase.

During the 18th century, the square of the earth's eccentricity has diminished 0,0000015325, the mean distance from the sun being = 1. This has increased the angular motion of the moon in that timeo, 20000001 285. As this augmentation is gradual, we must multiply the angular motion during the century by the half of this quantity, in order to obtain its accumulated effect., This will be found to be 9' very nearly, which exceeds that deduced, from a most careful comparison of the motion of the last two centuries, only by a fraction of a se-

As long as the diminution of the square of the eccentricity of the earth's orbit can be supposed proportional to the time, this effect will be as the fquares of the times. When this theory is compared with observations, the coincidence is wonderful indeed. The effect on the moon's motion is periodical, as the change of the folar eccentricity is, and its period includes millions of years. Its effect on the moon's longitude will amount to feveral degrees before the fecular acceleration change to a retardation.

Those who are not familiar with the disquisitions of

modern analysis, may conceive this question in the fol-

lowing manner.

Let the length of a lunar period be computed for the earth's distance from the sun for every day of the year. Add them into one fum, and divide this by their number, the quotient will be the mean lunar period. This will be found to be greater than the arithmetical medium between the greatest and the least. Then suppose the eccentricity of the earth's orbit to be greater, and make the same computation. The average period will be found still greater, while the medium between the greatest and least periods will hardly differ from the former. Something very like this may be observed without any calculation, in a cafe very fimilar. The angular velocity of the fun is inverfely as the square of his distance. Look into the solar tables, and the greatest diurnal motion will be found 3673", and the least 3433". The mean of these is 3553", but the medium of the whole is 3548". Now make a fimilar observation in tables of the motion of the planet Mars, whose eccentricity is much greater. We shall find that the medium between the greatest and least exceeds the true medium of all in a much greater proportion.

Thus has the patient and affiduous cultivation of the and utility Newtonian discoveries explained every phenomenon, and of this law. enabled us to forefee changes in them which no examination of the past appearances, unaffisted by this theory, could have pointed out, and which must have exceedingly embarrassed future astronomers. This great but fimple law of deflection represents every phenomenon of the system in the most minute circumstances. Far from fearing that future experience may overturn this law, we may rest affured that it will only confirm it more and more; and we may confide in its most remote confequences as if they were actually observed.

It is discovered by observation, that the deflection of deflection the moon to the earth, and of the planets to the fun, of he earth are accompanied by an equal and opposite deflection of and moon, the earth to the moon, and of the fun to the planets.

The tendency of the earth to the moon is plainly indicated by the rife of the waters of the ocean under the

moon, and on the opposite side of the earth. Sir Isaac Newton tried what should be the result of a tendency of the water to the moon. His investigation of this question was very similar to that in his lunar theory. We may conceive the moon to be one of many millions of particles of a fluid, occupying a globe as big as the lunar orbit. Each will feel a fimilar diffurbing force, which will diminish its tendency to the earth in the neighbourhood of the place of conjunction and opposition, and will increase it in the neighbourhood of the quadratures. They cannot therefore remain in equili- Proved by brio in their spherical form; they must fink in the qua-the ebbig dratures, and rife in the conjunction and opposition, till and flowtheir greater height compensates for the diminisheding of the weight of each particle. In like manner, the waters of the fea, ocean must fink on those parts of the earth where the moon is feen in the horizon, and must rise in those which have the moon in the zenith or nadir. All these effects are not only to be feen in general, but they may all be calculated, and the very form pointed out which the furface of the ocean must assume: and thus a tendency of every particle of the ocean to the moon, inverfely proportional to the square of its distance from it, gives us. a theory of the ebbing and flowing of the sea. This is delivered in fufficient detail in the article Tide of the Encyclopædia Britannica, and therefore need not be infifted on in this place. The same inference must be drawn from the precession of the equinoxes produced by the action of the moon on the protuberant matter of our equatoreal regions. See Precession in the

But the mutual tendency of the earth and moon is And by difclearly feen in a phenomenon that is much more fimple, ferent com-If we compute the fun's place in the heavens, on the putations fupposition that the earth describes areas proportional lace in the to the times, we shall find it to agree with observation heavens. at every new and full moon: But at the first quarter the fun will be observed about 9 seconds too much advanced to the castward; and at the last quarter he will be as much to the westward of his calculated place. In all intermediate positions, the deviation of the observed from the computed place of the fun will be o feconds, multiplied by the fine of the moon's distance from conjunction or opposition. In short, the appearances will be the same as if it were not the earth which described areas proportional to the times round the fun, but that a point, lying between the earth and moon, and very near the earth's furface, were describing the ellipse round the fun, while the earth and moon revolve round this point in the course of a lunation, having the point always in the line between them, in the same manner as if they were on the extremities of a rod which turns round this point, while the point itself revolves round the fun.

This then is the fact with respect to the motions: and the earth in a month describes an orbit round this common centre of the earth and moon. It cannot do this unless it be continually deflected from the tangent to this orbit; therefore it is continually deflected toward the moon: and the momentum of this deflection, that is, its quantity of motion, is the same with that of the moon's deflection, because their distances from the common centre are as their quantities of matter inverfely.

Appearances perfectly fimilar to these oblige us to

bfervaw of mo-

ension

affirm that the fun is continually deflected toward the planets. Astronomical instruments, and the art of obferving, have been prodigiously improved fince Sir Isaac Newton's time; and the most scrupulous attention has been paid to the fun's motion, because it is to his place in the universe that continual reference is made in computing the place of all the planets. He is supposed at rest in the common focus of all their orbits; and the observed distance of a planet from the sun is always confidered as the radius vector. If this be not the case, the orbital motions contained in our tables are not the absolute motions of the planets, nor the deflections from the tangents the real deflections from absolute rectilineal metion; and therefore the forces are not fuch as we infer from those miltaken deflections. Accordingly Sir Ifaac Newton, induced by certain metaphyfical confiderations, assumed it as a law of motion, that every action of a body A on another body B, is accompanied by an equal and contrary action of B on A. We do not fee the propriety of this affertion as a metaphyfical axiom. It is perfectly conceivable that a piece of iron will always approach a magnet when in its neighbourhood; but we do not fee that this obliges us to affert that therefore the magnet will also approach the iron. Those who explain the phenomena of magnetism by the impulse of a fluid, must certainly grant that there is no metaphyfical necessity for another stream of fluid impelling the magnet toward the iron. And accordingly this, and the fimilar reciprocity in the phenomena of electricity, have always been confidered as deductions of experimental philosophy; yet we observe the same reciprocity in all the actions of fublunary bodies; and Newton's third law of motion is received as true, and admitted as a principle of reasoning. But we apprehend that it was hafty in this great philosopher, and that law unlike his ferupulous caution, to extend it to the planetary motions. He did, however, extend it, and afferted, that as each planet was deflected toward the fun, the fun was equally (in respect of momentum) deflected toward each planet, and that his real motion was the composition of all those simultaneous deslections. He afferted, that there was a certain point round which the fun and his attending planets revolved; and that the tion, and how to afcertain the accumulated refult of orbit of a planet, which our measurements determined them all in any state of combination. by continual reference to the fun as to a fixed body, was not the true orbit, but confifted of the contemporaneous orbits of that planet and of the fun round this fixed point. Any little fector of the apparent orbit was greater than the corresponding sector of the planet's true orbit in absolute space, and the apparent motion was compounded of the true motion of the planet, and the opposite to the true motion of the sun. After a most ingenious and refined investigation, he showed that, notwithstanding this great difference of the Keplerean laws from the truth, the inference, with respect to the law of planetary deflection, is just, and that not only the apparent deflections are in the inverse duplicate ratio of the distances from the fun, but that the real deflections vary in the fame ratio of the diffances from the fixed point, and also from the fun; for he showed that the distances from the fun were in a conflant ratio to the distances from this point. He shewed also that the same forces which produced the contemporaneous revolution of a planet and the fun round the centre of the fystem, would produce a revolution of

the planet in a fimilar orbit round the fun (supposed to be held fast in his place) at the same distance which really obtains between them, with this fole difference, that the periodic time will be longer, in the fubduplicate ratio of the quantity of matter in the fun to the quantity of matter of the fun and planet together. Areas will be defcribed proportional to the times, and the orbit will be elliptical; but the ratio of the fquares of the periodic times will not be the fame with the ratio of the cubes of the distances, unless all the planets are

Thus was the attention of astronomers directed to a number of apparent irregularities in the motion of the earth, which must result from this derangement of the fun, which they had imagined to remain itedfast in his place. They were told what to expect, and on what positions of the planets the kind and quantity of every irregularity depended. This was a most inviting field of observation to a curious speculatift; but it required the nicest and most expensive instruments, and an uninterrupted feries of long continued observations, sufficient to occupy the whole of a man's time. Fortunately the accurate determination of the folar and lunar motions were of the utmost importance, nay, indispensably necessary for solving the famous problem of the longitude of a ship at sea: and thus the demands of commercial Europe came in aid of philosophical curiosity, and oc-cassioned the erection of observatories, first at Greenwich, and foon after at Paris and other places, with eftablishments for astronomers, who should carefully watch the motions of the fun and moon, not neglecting the other planets.

The fortunate refult of all this folicitude has been the Confirmed complete establishment of the Newtonian conjecture (for by observafo we must still think it), and the verification of New-tion. ton's affertion, that action was accompanied, through the whole folar fystem, by an equal and contrary reaction. All the inequalities of the folar motion predicted by Newton have been observed, although they are frequently fo complicated that they could never have been detected, had not the Newtonian theory directed us when to find any of them pretty clear of complica-

But in the course of this attention to the motions of the fun and moon, the planets came in for a share, and confiderable deviations were found, from the supposition that all their deflections were directed to the fun, and were in the inverse duplicate ratio of their distances. The nice observation shewed, that the period of Jupiter was fomewhat shorter than Kepler's law required.

A flight reflection shewed that this was no inconfiftency; because the common centre of the conjoined orbits of the Sun and Jupiter was fenfibly diftant from the centre of the fun, namely, about the 1100th part of the radius vector; and therefore the real deflection was about a 2200th part less than was supposed. It was now plain that the distances to which the Keplerean law must be applied, are the distances, not from the sun, but from the fixed point round which the fun and planets revolve. This difference was too fmall to be observed in Kepler's time; but the feeming error is only a confirmation of the Newtonian philosophy.

But there are other irregularities which cannot be ex-plained in this manner. The planetary orbits change

their position; their aphelia advance, their nodes recede, their inclination to each other vary. The mean mo- the planet approaches the node, and diminishes while tions of Saturn and Jupiter are subject to considerable the planet retires from it.

changes, which are periodical.

of the pla- verfality and reciprocity of the deflections of the pla- motions of Jupiter and Saturn, which has long employ-the motion Deflection wards each nets and the fun, than he also suspected that they were costinually deflected towards each other. He immeother. the more general refults of fuch a mutual action. They

may be conceived in this way.

Let S (fig. 5.) reprefent the fun, E the earth, and I Plate VI. Jupiter, describing concentric orbits round the centre of the fyllem. Make IS: EA = EI2: SI2. Then, if IS be taken to represent the deflection of the fun toward Jupiter, EA will represent the deflection of the Earth to Jupiter. Draw EB equal and parallel to SI, General re- and complete the parallelogram EBAD. ED will refult of fuch present the disturbing force of Jupiter. It may be remutual ac- folved into EF, perpendicular to ES, and EG in the direction of SE. By the first of these the earth's angular motion round the fun is affected, and by the fecond its deflection toward him is diminished or increased.

In consequence of this first part of the disturbing force, the angular motion is increased, while the earth approaches from quadrature to conjunction with Jupiter (which is the case represented in the figure), and is diminished from the time that Jupiter is in opposition till the earth is again in quadrature, westward of his opposition. The earth is then accelerated till Jupiter is in conjunction with the fun; after which it is retard-

ed till the earth is again in quadrature.

The earth's tendency to the fun is diminished while Jupiter is in the neighbourhood of his opposition or conjunction, and increased while he is in the neighbourhood of his stationary positions. Jupiter being about 1000 times less than the fun, and 5 times more remote, IS must be considered as representing 11000th of the earth's deflection to the fun, and the forces ED and EG are to be measured on this scale.

In consequence of this change in the earth's tendency to the fun, the aphelion fometimes advances by the diminution, and fometimes retreats by the augmentation. It advances when Jupiter chances to be in oppofition when the earth is in its aphelion; because this diminution of its deflection towards the fun makes it later before its path is brought from forming an obtuse angle with the radius vector, to form a right angle with it. Because the earth's tendency to the fun is, on the whole, more diminished by the disturbing force of Jupiter than it is increased, the aphelion of the earth's orbit advances on the whole.

In like manner the aphelia of the inferior planets advance by the diffurbing forces of the fuperior: but the aphelion of a superior planet retreats; for these reasons, and because Jupiter and Saturn are larger and more powerful than the inferior planets, the aphelia of them all advance while that of Saturn retreats.

In consequence of the same disturbing forces, the node of the disturbed planet retreats on the orbit of the disturbing planet; therefore they all retreat on the ecliptic, except that of Jupiter, which advances by retreating on the orbit of Saturn, from which it fuffers the greatest disturbance. This is owing to the particular position of the nodes and the inclinations of the orbits.

The inclination of a planetary orbit increases while

M. de la Place has completed this deduction of the A peculia-Sir Ifaac Newton had no fooner discovered the uni- planetary inequalities, by explaining a peculiarity in the rity exed the attention of aftronomers. The accelerations and of Jupiter retardations of the planetary motions depend, as has and Saturn, diately obtained a general notion of what should be been shown, on their configurations, or the relative quarters of the heavens in which they are. Those of Mercury, Venus, the Earth, and Mars, arifing from their mutual deflections; and their more remarkable deflections to the great planets Jupiter and Saturn, nearly compensate each other, and no traces of them remain after a few revolutions: but the positions of the aphelia of Saturn and Jupiter are fuch, that the retardations of Saturn fenfibly exceed the accelerations, and the anomaliftic period of Saturn increases almost a day every century; on the contrary, that of Jupiter diminishes. M. de la Place shows, that this proceeds from the position of the aphelia, and the almost perfect commensurability of their revolutions; five revolutions of Jupiter making 21,675 days, while two revolutions of Saturn make 21,538, differing only 137 days.

Supposing this relation to be exact, the theory shews, that the mutual action of these planets must produce mutual accelerations and retardations of their mean motions, and afcertains the periods and limits of the fecular equations thence arifing. These periods include several centuries. Again, because this relation is not precise, but the odd days nearly divide the periods already found, there must arise an equation of this secular equation, of which the period is immenfely longer, and the maximum very minute. He shews that this retardation of Saturn is now at its maximum, and is diminishing again, and will, in the course of years, change to an

acceleration.

This investigation of the small inequalities is the most intricate problem in mechanical philosophy, and has been completed only by very flow degrees, by the arduous efforts of the greatest mathematicians, of whom M. de la Grange is the most eminent. Some of his ge-

neral refults are very remarkable.

He demonstrates, that fince the planets move in one direction, in orbits nearly circular, no mutual disturbances make any permanent change in the mean diftances and mean periods of the planets, and that the periodic changes are confined within very narrow limits. The orbits can never deviate sensibly from circles. None Oscillari of them ever has been or will be a comet moving in a of the very eccentric orbit. The ecliptic will never coincide tem. with the equator, nor change its inclination above two degrees. In short, the solar planetary system oscillates, as it were, round a medium state, from which it never fwerves very far.

This theory of the planetary inequalities, founded on the universal law of mutual deflection, has given to our tables a precision, and a coincidence with observation, that furpaffes all expectation, and infures the legitimacy of the theory. The inequalities are most fensible in the motions of Jupiter and Saturn; and these present themfelves in fuch a complicated state, and their periods are fo long, that ages were necessary for discovering them by mere observation. In this respect, therefore, the theory has outflripped the observations on which it is

founded,

38 uthentity of the ndian aronomy.

heavens.

Action of

the Indians affign to these two planets, and which appeared fo inaccurate that they hurt the credit of the science of those ancient astronomers, are now found precifely fuch as must have obtained about three thousand years before the Christian era; and thus they give an authenticity to that ancient aftronomy. The periods which any nation of astronomers assign to those two planets would afford no contemptible mean for determining

the age in which it was observed.

The following circumstance is remarkable: Suppose Jupiter and Saturn in conjunction in the first degree of Aries; twenty years after, it will happen in Sagittarius; and after another twenty years, it will happen in Leo. It will continue in these three figns for 200 years. In the next 200 it will happen in Taurus, Capricornus, and Virgo; in the next 200 years, it will happen in Gemini, Aquarius, and Libra; and in the next 200 years, it will happen in Cancer, Pisces, and Scorpio:
Origin of then all begins again in Aries. It is highly probable the aftrolo-that these remarkable periods of the oppositions of Jugreat divi-fion of the Piter and Saturn, progressive for 40 years, and oscillating during 160 more, occasioned the astrological divifion of the heavens into the four trigons, of fire, air, earth, and water. These relations of the figns, whichcompose a trigon, point out the repetitions of the chief irregularities of the folar fyftem.

M. de la Place observes (in 1796), that the last difcovered planet gives evident marks of the action of the reit; and that when these are computed and taken into the account of its bygone motions, they put it beyond doubt that it was feen by Flamstead in 1690, by Mayer

in 1756, and by Monnier in 1769.

We have hitherto overlooked the comets in our acthe councis count of the mutual disturbances of the folar fystem. Their number is very great, and they go to all quarters of the universe: but we may conclude, from the wonderful regularity of the planetary motions, when all their own mutual actions are taken into account, that the quantity of matter in the comets is very inconsiderable. They remain but a short time in the neighbourhood of the planets, and they pass them with great rapidity. Some of them have come very near to Jupiter, but left no trace of their action in the motions of his fatellites. They doubtless contribute, in general, to make the ap-

fides of the planetary orbits advance.

They are affected by On the other hand, the comets may be confiderably the planets affected by the planets. The very important phenomenon of the return of the comet of 1682, which was to decide whether they were revolving planets describing ellipses, or bodies which came but once into the planetary regions, and then retired for ever, caufed the aftronomers to confider this matter with great care. Halley had shown, in a rough way, that this comet must have been confiderably affected by Jupiter. Their motion near the aphelion must be so very slow, that a very small change of velocity or direction, while in the planetary regions, must considerably affect their periods. Halley thought that the action of Jupiter might change it half a year. Mr Clairaut, by confidering the diffurbing forces of Jupiter and Saturn through the whole revolution, showed that the period then running would exceed the former nearly two years (618 days), and affigned the middle of April 1759 for the time of its perihelion. It really passed its perihelion on the 12th of March. This

founded. It is very remarkable, that the periods which was a wonderful precision, when we reflect that the comet had been seen but a very few days in its former

apparitions.

A comet observed by Mr Prosperin and others in 1771 has greatly puzzled the astronomers. Its motions appear to have been extremely irregular, and it certainly came so near Jupiter, that his momentary influence was at least equal to the fun's. It has not been recognised fince that time, although there is a great probability that it is continually among the planets.

It is by no means impossible, nor highly improbable, Confethat, in the course of ages, a comet may actually meet quence of a one of the planets. The effect of such a concourse must planet be dreadful; a change of the axis of diurnal rotation meeting. must refult from it, and the fea must desert its former bed and overflow the new equatorial regions. The shock and the deluge must destroy all the works of man, and most of the race. The remainder, reduced to mifery, must long struggle for existence, and all remembrance of former arts and events must be lost, and every thing must be invented anew. There are not wanting traces of fuch devastations in this globe: strata and things are now found on mountain tops which were certainly at the bottom of the ocean in former times; remains of tropical animals and plants are now dug up in the circumpolar regions. Tempora mutantur, et nos mutanur in illis.

It is plain, that when we know the direction and the intenfity of the disturbing force, we can tell what will be the accumulated effect of its action for any time. 'The direction is eafily determined by means of the distance: but how shall we determine the intensity? Since we fee that the whole waters of the ocean are deflected toward the moon, and have fuch probable evidence that planetary deflection is mutual; it follows, that the moon is deflected towards every drop of water, and that all the matter in one body is deflected towards all the matter in another body; and therefore that the deflection towards the fun or a planet is greater or less in proportion to its quantity of matter. Newton indeed thought it unreasonable to suppose that a planet was deflected to the centre of the fun, which had no diftinguishing physical property; and thought it more probable that the deflection of a planet to the sun was the accumulated deflection of every particle in the planet to every particle in the fun. But he was too fcrupulous to take this for granted. He therefore endeavoured to discover what would be the sensible deslection of one fighere to another, when each confifted of matter, every particle of which was deflected to every particle of the other with an intensity inversely proportional to the square of the distance from it. By help of a most beau-Tendency tiful and fimple process, he discovered, that the ten of opherical deney of a particle of matter to a spherical surface should be dies to dency of a particle of matter to a spherical surface, shell, wards each or folid, of uniform dentity at equal diffances from the other, dicentre, was the same as if all the particles in the fur-rectly as the face, shell, or folid, were united in its centre: hence it quantity of matter, and legitimately followed, that the mutual tenderrey of fohe-inverfely as rical furfaces, shells, or solids, was proportional to the the square quantities of matter in the attracting body, and inverse of the di-ly as the square of the distance of their centres; and their centhus the law of attraction, competent to every particle tree. of planetary matter, was the same with that which was observed among spherical bodies consisting of such matter. And it is remarkable, that the inverse duplicate ra-

tio of the distances is the only law that will hold, both net. If the quantity in the Earth be considered as the with respect to single particles and to globes composed of fuch particles. He also demonstrated, that a particle placed within a sphere was not affected by all the shell, which was more distant than itself from the centre, being equally attracted on every fide, and that it tended toward the centre of a homogeneous fohere, on the furface of which it was placed, with a force pro-

portional to its distance from the centre.

Newton faw a cafe in which it was possible to discover whether the tendency of the matter of which the planets confifted was directed to a mathematical centre void of any physical properties, or whether it was the refult of its united tendency to all the matter of the planet. He demonstrated, that if the earth consisted of matter which tended to the centre, it behoved it to affume the form of an elliptical spheroid, in consequence of the centrifugal force ariting from its diurnal motion, and that the polar axis must be to its equatorial diameter as 577 to 578; but if every particle tends to every other particle in the inverse duplicate ratio of the distance from it, the form must still be elliptical, but more protuberant, and the polar axis must be to the equatorial diameter as 230 to 231. Then only will a column of water from the pole to the centre balance a column from the equator to the centre. He also shewed what should be the vibrations of pendulums in different latitudes, on both suppositions. Mathematicians were eager therefore to make those experiments on pendulums, and to determine the figure of the earth by the measurement of degrees of the meridian in different latitudes. The refult of their endeavours has been decidedly in favonrs of the mutual tendency of all matter. This has been farther confirmed by the observations of the mathematicians who measured the degrees of the meridian in Peru, and by Dr Maskelyne in Britain, who found that a pendulum suspended in the neighbourhood of a great and folid mountain, fenfibly deviated from the true vertical, and was deflected toward the mountain.

Proportion - From a collective view of all these circumstances, Sir alquantuies Haac Newton concluded, with great confidence, that of matter in that the word any planet was the united deflecplanets de tion toward every particle of matter contained in it. This enabled him to determine the intensity of the planetary diffurbing forces, by previously afcertaining the proportions of their quantities of matter. This proportion, the discovery of which seems above our reach, is easily ascertained in all those bodies which have others revolving round them: for the deflection of the revolving body, being occasioned by all the matter in the central body, will be proportional (cateris paribus) to the quantity of matter in the central body, and therefore will give us a measure of that quantity. Would we compare the quantity of matter in Jupiter with the quantity of matter in the fun, we have only to suppose that a planet revolves round the fun at the distance of Jupiter's fourth fatellite. Kepler's third law will tell us the time of its revolution. The distances, in this case, being the same, the centripetal forces, and consequently the quantities of matter in the central bodies, will be inversely as the squares of the periodic times of the revolutions around them. In this way have the quantities of matter been determined for the Sun, the the Earth, Jupiter, Saturn, and the last discovered plaunit, we have,

The Earth The newly discovered planet 17,75 Saturn - - -86,16 Jupiter The Sun 317,1 338343.

Thus we fee that the fun is incomparably bigger than any planet, having more than a thousand times as much matter as Jupiter, the most massy of them all. There is a confiderable uncertainty, however, in the proportion to the fun, because we do not know his distance nearer than within to the part. The proportions of the rest to each other are more accurate. The quantities of matter in Mercury and Mars can only be gueffed at: the quantity in Mercury may be called 0,1, and Mars may be called 0,12. Venus is supposed nearly equal to the Earth. This is concluded from the effect which the produces on the precession of the equinoxes and the equation of the fun's motion. The moon is supposed to be about to he fith of the earth, from the effect she produces on the tides and the precession of the equinoxes, compared with those produced by the fun.

When these quantities of matter are introduced into Sun's place the computation of the planetary inequalities, and the and the intenfity of the diffurbing forces affumed accordingly, transit of a the results of the computations tally so exactly with obtermined fervation, that we can now determine the fun's place exactly. for any moment within two or three feconds of a degree, and are certain of the transit of a planet within

one beat of the clock!

Jam dubios nulla caligine prægravat error; Queis superum penetrare domos atque ardua eæli Scandere sublimis genii concessit acumen.

HALLEY.

Sir Isaac Newton having already made the great difcovery of an universal and mutual dessection of all the matter in the folar fystem, was one day speculating on this subject, and comparing it with other deflections which he observed among bodics, such as magnets, &c. He confidered terrestrial gravity as a force of this kind. By the weight of terrestrial bodies they kept united with the earth. By its weight was the water of the Progress of ocean formed into a sphere. This force extended, with Newton's out any remarkable diminution, to the tops of the high-discovery est mountains. Might it not reach much farther? May it not operate even at the distance of the moon? In the same manner that the planetary force deflects the moon from the tangent to her orbit, and causes her to deferibe an ellipfe, the weight of a cannon ball deflects it from the line of its direction, and makes it describe a parabola. What if the deflecting force which incurvates her path towards the earth be the fimple weight of the moon? If the weight of a body be the same with the general planetary force, it will diminish as the square of its distance from the earth increases. Therefore, faid he to himself, fince the distance of the moon from the centre of the earth is about 50 times greater than the distance of the stone which I throw from my hand, and which is deflected 16 feet in one fecond, the weight of this stone, if taken up to the height of the moon, should be reduced to the 2500th part, and should there deflect 2500 thof 16 feet in a fecond; and the moon should deflect

deflect as much from the tangent in a fecond. Having the dimensions, as he thought, of the moon's orbit, he immediately computed the moon's deflection in a fecond; but he found it confiderably different from what he wished it to be. He therefore concluded that the planetary force was not the weight of the planet. For fome years he thought no more of it: but one day, in the Royal Society, he heard an account read of meafurements of a degree of the meridian, which showed him that the radius of the earth and the distance of the moon were very different from what he had believed them to be. When he went home he repeated his computation, and found, that the deflection of a stone was to the simultaneous deslection of the moon as the square of the moon's distance from the centre of the earth to the square of the stone's distance. Therefore the moon is deflected by its weight; and the fall of a stone is just a particular instance of the exertion of the universal planetary force. This computation was but roughly made at first; but it was this coincidence that excited the philosopher to a more attentive review of the whole subject. When every circumstance which can affect the refult is taken into account, the coincidence is found to be most accurate. The fall of the stone is not the full effect of its weight; for it is diminished by the rotation of the earth round its axis: It is also diminished by the weight of the air which it displaces: It is also diminished by its tendency to the moon. On the other hand, the moon does not revolve round the earth, but round a common centre of the earth and moon, and its period is about 120th shorter than if it revolved round the earth; and the moon's deflection is affected by the fun's diffurbing force. But all these corrections can be accurately made, and the ratio of the full weight of the stone to the full deflection of the moon ascertained. This has been done.

Terrestrial gravity therefore, or that power by which bodies fall or press on their supports, is only a particular instance of that general tendency by which the planets are retained in their orbits. Bodies may be said to gravitate when they give indications of their being gravits or heavy, that is, when they fall or press on their supports; therefore the planets may be said to gravitate when they give similar indications of the same tendency by their curvelineal motions. The general FACT, that the bodies of the solar system are mutually desiected toward each other, may be expressed by the verbal noun gravitation. Gravitation does not express a quality, but an event, a desiection, or a pressure.

The weight of a terrestrial body, or its pressure on its support, is the effect of the accumulated gravitation of all its particles; for bodies of every kind of matter sall equally sast. This has been ascertained with the utmost accuracy by Sir Isaac Newton, by comparing the vibrations of pendulums made of every kind of matter. Therefore their united gravitation is proportional to their quantity of matter; and we have concluded, that every atom of terrestrial matter is heavy, and equally heavy. We extend this conclusion to the sun and planets, and say, that the observed gravitation of a planet is the united gravitation of every particle. Therefore Sir Isaac Newton inferred, from a collective view of all the phenomena, that all matter gravitates to all matter with a source in the inverse duplicate ratio of the distance.

But we do not think that this inference is absolutely

certain. We acknowledge that the experiments on pendulums, confliting of a vaft variety of terrestrial matter, all of which performed their oscillations in equal times, demonstrate that the acceleration of gravity on those pendulums was proportional to their quantities of matter, and that equal gravitation may be affirmed of all terrestrial matter.

The elliptical motion of a planet is full proof that the accelerating power of its gravity varies in the inverse duplicate ratio of the distance; and the proportionality of the squares of the periods to the cubes of the distances, shows that the whole gravitations of the planets vary by the same law. But this third observation of Kepler might have been the same, although the gravitation of a particle of matter in Jupiter had been equal to that of a particle of terrestrial matter, provided that all the matter in Jupiter did not gravitate. If th of Jupiter had been fuch gravitating matter, his deflection from the tangent of his orbit would have been the same as at present, and the time of his revolution would have been what we observe. In order that the third law of Kepler may hold true of the planetary motions, no more is required than that the accumulated gravitation of the planet be proportional to its quantity of matter, and thus the matter which does not gravitate will be compensated by the superior gravitation of the reft.

But because we have no authority for faying that there is matter which gravitates differently from the rest, or which does not gravitate, we are entitled to suppose that gravity operates alike on all matter.

And this is the ultimatum of the Newtonian philo-which is fophy, that the folar fystem confists of bodies composed the ultimator matter, every particle of which is, in fact, continually tum of his desected by its weight toward every other particle in the philosophy. fystem; and that this desection, or actual deviation, or actual pressure, tending to deviation from uniform rectilineal motion, is in the inverse duplicate ratio of the distance.

This doctrine has been called the System of universal Objections gravitation; and it has been blamed as introducing an othelaw unphilosophical principle into science. Gravitation is of gravitafaid to be an occult quality; and therefore as unfit for founded. the explanation of phenomena as any of the occult qualities of Aristotle. But this reproach is unfounded; gravitation does not express any quality whatever, but a matter of fact, an event, an actual deflection, or an actual preffure, producing an actual deflection of the body preffed. These are not occult, but matters of continual observation. True, indeed, Newton does not deny, although he does not politively fay, that this deflection, pressure, or gravitation, is an effect having a cause. Gravity is laid to be this cause. Gravity is the being gravis or heavy, and gravitation is the giving indications of being heavy Heavinels therefore is the word which expresses gravitas, and our notion of the cause of the planetary deflections is the fame with our notion of heaviness. This may be indiffinct and unfatisfactory to a mind fastidiously curious; but nothing can be more familiar. The planet is deflected, because it is heavy. We are supposed to explain the fall of a stone through water very fatisfactorily, and without having recourfe to any occult quality, when we fay that it is heavier than the water; and we explain the rife of a piece of cork, when we say that it is not to heavy as the water.

The englanations of the mutual actions of the planets are equally fatisfactory, founded on the fame principles, and equally free from all fophittry or employment of occult canfes. The weight of a body is not its heaviness, but the effect of its heaviness. It is a gravitation, an actual pressure, indicated by its balancing the supposed heaviness of another body, or by its balancing the known elasticity of a spring, or by balancing any other natural power. It is fimilar to the pressure which a magnet exerts on a piece of iron. This may perhaps be produced by the impulse of a stream of sluid; so on may the weight of a heavy body. But we do not contensive and important knowledge by our knowledge of that law fa- this univerfal law; for we can now explain every phe-Listactory. nomenou, by pointing out how it is contained in this law; and we can predict the whole events of the folar fystem with unerring exactness. This should satisfy the most inquisitive mind.

But, nitimur in vetitum, semper cupimusque negata. There feems to be a fatal and ruinous disposition in the human mind, a fort of priapism of the understanding, that is irritated by every interdict of natural imperfection. We would take a microspope to look at light; we would know what knowing is, and we would weigh

heavinefs.

All who are acquainted with the writings of Aristotle have fome notion of his whimfical opinions on this fubject. He imagines that the planets are conducted in their orbits by a fort of intelligences, ionip Yuxai, which animate the orbs that wheel them round. Although this crude conception met with no favour in later times, another, not more reasonable, was maintained by Leibnitz, who called every particle of matter a monad, and gave it a perception of its fituation in the universe, of its distance and direction from every other, and a power and will to move itself in conformity to this fituation, by certain constant laws. This orace Yuxa in the Monad is nothing but an aukward fubstitute for the principle of gravitation, which the learned infifted that Newton placed in every particle of matter as an innate power, and which they reprobated as unphilosophical. But in what respect this perception and active propenfity is better, we do not perceive. It is more complex, and involves every notion that is reprehensible in the other; and it offers no better explanation of the phenomena.

But Newton is equally anxious with other philosophers not to ascribe gravity to matter as an innate inherent property. In a letter to Dr Bently, he earnestly requests him not to charge him with fuch an absurd opinion. It is an avowed principle, that nothing can all on any thing that is at a distance; and this is considered as an intuitive axiom. But it is furely very obscure; for we cannot obtain, or at least convey, clear notions of the terms in which it is expressed. The word ad is entirely figurative, borrowed from animal exertions; it is therefore unlike the expression of any thing intitled to the appellation of intuitive. If we try to express it without figure, we find our confidence in its certainty greatly diminished. Should we say that the condition of a body A cannot depend on another body B that is themselves. at distance from it, we believe that no perion will fay

as it is called, of the perfeverance of a body in a frate of relt, the only argument that is offered is, that no cause can be affigued why it should move in one direction rather than in another: but should any one say that another body is near it, to the right hand, and that this is a lufficient reason for its moving that way, we know no method by which this affertion can be shown to be

Such, however, has been the uniform opinion of philosophers. Nihil movetur (fays Leibnitz) nisi a contiguo et moto. The celebrated mathematician Fuler having discovered, as he thought, the production of a pressure, like gravity, from motion, fays, " as motion may arite from preffing powers, so we have feen that preffing powers may arise from motion. We see that both exist in the universe. It is the buff of a philosopher to discover, by reason and observation, which is the origin of the other. It is incompatible with reason, that budies should be possessed of inherent tendencies; much more that powers should exist independently. Farther, that philosopher must be reckoned to have affigued the true causes of phenomena, who demonstrates that they arise from motion; for motion, once existing, must be preserved for ever. In the present instance (a certain whimfical fact of a ball running round the infide of a hoop) we fee how a preffing power may be derived from motion; but we cannot fee how powers can exert themfelves, or be preserved, without motion. Wherefore we may conclude that gravity, and all other powers, are derived from motion; and it is our bufiness to investigate from what motions of what bodies each observed power derives its origin."

Accordingly many attempts have been made to trace the planetary deflections to their origin in the motion of fame impelling matter; but these attempts could not be fuccefsful, because they are all built on hypotheses. It has been affumed, that there is a matter diffused through the celestial spaces; that this matter is in motion, and by its impulse moves the planets: but the only reason that can be given for the existence of this matter is the difficulty we find in explaining the planetary deflections without it. Even if the legitimate confequences of this hypothesis were consistent with the phenomena, we have not advanced in our knowledge, nor obtained any explanation. We have only learned, that the appearances are fuch as would have obtained had fuch a matter existed and acted in this manner. The observed laws of the phenomena are as extensive as those of the hypothesis; therefore it teaches us no-

thing but what we knew without it.

But this is not all that can be faid against those at-Incomisso tempts; their legitimate consequences are inconsistent with cy of some the phenomena. By legitimate consequences we mean of these the laws of motion. These must be admitted, and are counts w admitted, by the philosopher who attempts to explain mena. the planetary motions by impulse. It would be ridiculous to suppose a matter to fill the heavens, having laws of impulse different from those that are observed by common matter, and which laws must be contrived fo as to answer the purpose. It would be more simple at once to affign those pro re nata laws to the planets

Yet fuch was the explanation which the celebrated that he makes this affertion from perceiving the abfur- Descartes offered by his hypothesis of vertices, in which dity of the contrary proposition. In the demonstration, the planets were immersed and whirled round the fun.

Vain attempts to account for it.

Defeartes

ed any partifans; yet it long maintained its authority, and still has zealous defenders. Till Sir Isaac Newton faw the indispensible necessity of mathematical invostigation in every question of matter in motion, no person had taken the trouble of giving any thing like a diffinct description of those vortices, the circumstances of their motion, and the manner of their action; all determined with that precision that is required in the explanation: for this must always be kept in mind, that we want an explanation of the precise motions which have been obferved, and which will enable us to predict those which are yet to happen. Men were contented with some vague notion of a fort of fimilarity between the effects of fuch vortices and the planetary motions in a few general circumstances; and were neither at the trouble to confider how these motions were produced, nor how far they tallied with the phenomena. Their account of things was only fit for careless chat, but unworthy of the attention of a naturalist. But since this explanation came from a person deservedly very eminent, it was respected Examined by Newton, and he honoured it with a ferious examiby Newton nation. It is to this examination alone that we are indebted for all the knowledge that we have of the conflirtion of a fluid vortex, of the motions of which it is tusceptible, of the manner in which it can be produced, the laws of its circulation, and the effects which it can produce. We have this account in Sir Ifaac Newton's Principles of Natural Philosophy; and it contains many very curious and interesting particulars, which have been found of great fervice in other branches of mechanical philosophy. But the result of the examination was fatal to the hypothesis; shewing that the motions which were possible in the vortices, and the effects which they must produce, are quite incompatible with the appearances in the heavens. We do not know one person who has acquired any reputation as a mechanician that now attempts to defend it; nor do we know of any other person besides Newton who has attempted to explain mathematically how the circulation of a fluid can produce the revolution of a planet, if we except Mr Leibnitz, the celebrated rival of the British philosopher. Top th fi. This gentleman published in the Leipsic Review in of Leibnitz. 1689, three years after the publication of the Principia, an attempt to explain the elliptical motion of the planets, and the description of areas proportional to the times by the impulse of a vortex. It must not be passed over in this place, because it acquired great authority in Germany, and many of that country still affirm that Leibniz is the discoverer of the law of planetary gravitation, and of the mechanical conflitution of the folar fystem. We cannot help thinking this explanation the most faulty of any, and a most disingenuous plagiarism from the writings of Newton.

Mr Leibnitz supposes a fluid, circulating round the fun in such a manner that the velocity of circulation in every part is inverfely as its distance from the sun. (N. B. Newton had shown that such a circulation was possible, and that it was the only one which could be generated in a fluid by an action proceeding from the centre). Leibnitz calls this harmonical circulation. He supposes that the planet adopts this circulation in every part of its elliptical orbit, obeying without any refiftance the motion of this fluid. He does not ascribe this to the impulse of the fluid, saying expressly that the pla-SUPPL. VOL. I. Part I.

It is aftonishing that so crude a conception ever obtainnet follows its motion, non abrepta tamen, fed tranquilliter quasi natante. The planet therefore has no tendency to persevere in its former state of motion. Why therefore does it not follow this harmonic motion exactly, and describe a circle tranquilliter natans? This is owing, fays Leibnitz, to its centrifugal force, by which it perseveres in a state of rectilineal motion. It has no tendency to preserve its former velocity, but it perseveres in its former direction. The planet therefore is not like common matter, and has laws of motion peculiar to itself; it was needless therefore to employ any impulse to explain its motions. But to proceed: This centrifugal force must be counteracted in every point of the orbit. Leibnitz therefore supposes that it is also urged toward the centre by a folicitation like gravity or attraction. He calls it the paracentric force. He computes what must be its intensity in different parts of the orbit, in order to produce an elliptical motion, and he finds that it must be inversely as the square of the distance from the centre (for this reason he is frequently quoted by Bernoulli, Wolff, and others, as the difcoverer of the law of gravitation). But Leibnitz arrives at this result by means of feveral mathematical blunders. either arising from his ignorance at that time of fluxionary geometry, or from his perceiving that an accurate procedure would lead him to a conclution which he did not wish: for we have seen (and the demonstration is adopted by Leibnitz in all his posterior writings of this kind), that if the ordinary laws of motion are observed, a body, actuated by this paracentric force alone, will describe an ellipse, performing both its motion of harmonic circulation, and its motion of approach to and recefs from the centre, without farther help. Therefore, if the harmonic circulation is produced by a vortex, a force inverfely as the square of the distance from the centre, combined with the harmonic circulation, will produce a motion entirely different from the elliptical. It is demonstrated, that the force which is necessary for describing circles at different distances, with the angular velocity of the different parts of the orbit, is not in the inverse duplicate, but in the inverse triplicate, ratio of the distances This must have been the nature of his paracentric force, in order to counteract the centrifugal force arising from the harmonic circulation. There-Disingenulfore Leibnitz has not arrived at his conclusion by just ty of the reasoning, nor can be said to have discovered it. He author. fays, Vieleo hanc propositionem innotuisse viro celiberrimo Isaaco Newtono, licet non possim judicare quomodo ad eam pervenerit. This is really somewhat like impudence. The Principia were published in 1686. They were reviewed at Leiplic, and the Review published in 1687. Leibnitz was at that time the principal manager of that Review. When Newton published, Leibnitz was living at Hanover, and a copy was fent him, within two months of its publication, by Nicholas Facio, long before the Review. The language of the Review has feveral fingularities, which are frequent in Leibnitz's own composition; and few doubt of its being his writing. Befides, this proposition in the Principia had been given to the Royal Society several years before, and was in the records before 1684. These were all fcen by Leibnitz when in England, being lent him by his friend Collins.

We think that the opinion which a candid person must form of the whole is, that Leibnitz knew the proposition, and attempted to demonstrate it in a way that would make it pass for his own discovery; or that he only knew the enunciation, without understanding the principles. His harmonic circulation is a clumfy way of explaining the proportionality of areas to the times; and even this circulation is borrowed from Newton's differtation on the Cartefian vortices, which is also contained in the Leipfic Review above mentioned. Leibnitz was by this time a competitor with Newton for the honour of inventing the fluxionary mathematics, and was not guiltless of acts of disingenuity in afferting his claim. He published at the same time, in the same Review, an almost unintelligible differtation on the refistance of fluids, which, when examined by one who has learned the subject by reading the Principia of Newton, affords an enigmatical description of the very theory published by Newton, as a necessary part of his great

But besides all the above objections to Leibnitz's theory of elliptical motion, we may ask, What is this paracentric force? He calls it like gravity. This is precisely Newton's doctrine. But Leibnitz supposes this also to be the impulse of a fluid. It would have been enough had he explained the action of this fluid, without the other circulating harmonically. He defers this explanation, however, to another opportunity. It must have very fingular properties: it must impel the planet without disturbing the other sluid, or being disturbed by it. He also defers to another opportunity the explaining how the squares of the periodic times of different planets are proportional to the cubes of the mean distances; for this is quite incompatible with the harmonic circulation of his vortex. This would make the squares of the periods proportional to the distances. He has performed neither of these promises. Several years after this he made a correction of one of his mathematical blunders, by which he destroyed the whole of his demonstration. In short, the whole is such a heap of obfcure, vague, inconfiftent affumptions, and fo replete with mathematical errors, that it is aftonishing that he had the ignorance or the effrontery to publish it.

There is another hypothesis that has acquired some Hypothelis of Le Sage. reputation. M. le Sage of Geneva supposes, that there passes through every point of the universe a stream of fluid, in every direction, with aftonishing velocity. He supposes that, in the densest bodies, the vacuity is incomparably more bulky than the folid matter; fo that a folid body somewhat resembles a piece of wire cagework. The quantity of fluid which passes through will be incomparably greater than that of the intercepted fluid; but the impulse of the intercepted fluid will be fenfibly proportional to the quantity of folid matter of the body. A fingle body will be equally impelled in every direction, and will not be moved; but another body will intercept fome fluid. Each will intercept fome from the other; and the impulse on B, that is intercepted by A, will be nearly proportional to the matter in A, and inversely proportional to the square of its distance from B; and thus the two bodies will appear to tend toward each other by the law of gravitation.

M. le Sage published this in a work called Chimie Mechanique, and read lectures on this doctrine for many years in Geneva and Paris to crouded audiences. It is also published by Mr Prevost in the Berlin Memoirs,

under the name of Lucrece Newtonien; and there are many who confider it as a good explanation of gravitation: for our part, we think it inconceivable. motions of the planets, with undiminished velocity, for more than four thousand years, appears incompatible with the impelling power of this fluid, be its velocity what it will. The absolute precision of the law of gravitation, which does not show the smallest error during that time, is incompatible with an impulse which cannot be exally proportional to the quantity of matter, nor to the reciprocal of the square of the distance, nor the fame on a body moving with the rapidity of the comet of 1680 in its perihelion, as on the planet Saturn, whose motion is almost incomparably slower. What is the origin of the motion of this fluid? Why does it not destroy itself by mutual impulse, fince it is continually passing through every point? &c.

We have already observed that Newton expressed the Ether of fame anxiety to avoid the supposition of action among Newton bodies at a distance. He also feemed to show some dis-difficulposition to account for gravitation by the action of a ties. contiguous fluid. This is the subterfuge so much recurred to by precipitate speculatifts, by the name of the ether of Sir Isuac Newton. He supposes it highly elastic, and much rarer in the pores of bodies and in their vicinity than at a distance; therefore exceedingly rare in the fun, and denfer as we recede from him. Being highly elastic, and repelled by all bodies, it must impel them to that fide on which it is most rare; therefore it must impel them toward the sun. This is enough of its general constitution to enable us to judge of its fitness for Newton's purpose. It is wholly unfit; for fince it is fluid, unequally dense and elastic, its particles are not in contact. Particles that are elastic, and in a flate of compression, and in contact, cannot be sluid; they must be like so many blown bladders compressed in a box; therefore they are not in contact; therefore they are elastic by mutual repulsion; that is, by acting on each other at a distance. It is indifferent whether this distance is a million of miles, or the millionth part of a hair's breadth; therefore this fluid does not free Newton from the supposition which he wishes to avoid. Nay, it can be demonstrated, that in order to form a fluid which shall vary in density from the sun to the extremity of the folar fystem, there must be a mutual repulfion extending to that distance. This is introducing millions of millions of the very difficulties which Newton wished to avoid; for each particle presents the same difficulty with a planet.

We would now ask these atomical philosophers, why they have, in all ages, been fo anxious to trace the celeftial motions to the effects of impulse? They imagine that they have a clear perception of the communication of motion by impulse, while their perception of the production of it in any other way is obscure. Seeing, in a very numerous and familiar collection of facts, that motion is communicated by impulse, they think that it is communicated in no other way, and that impulse is the only moving power in nature.

But is it true that our notion of impulse is more clear Our notion than that of gravitation? Its being more familiar is no of impufe argument. A cause may be real, though it has exerted than of gra itself but once finee the beginning of time. In no case vitation. do we perceive the exertion of the cause; we only perceive the change of motion. The conflitution of our

mind makes us confider this as an effect, indicating a cause which is inherent in that body which we always fee affociated with that change. Granting that our perception of the perseverance of matter in its state of motion is intuitive, it by no means follows that the body A in motion must move the body B by striking it. The moment it strikes B, all the metaphysical arguments for A's continuance in motion are at an end, and they are not in the least affected by the supposition that A and B should continue at rest after the stroke; and we may defy any person to give an argument which will prove that B will be moved; nay, the very existence of B may, for any thing we know to the contrary, be a sufficient reason for the cessation of the motion of A. The production of motion in B, by the impulse of A, must therefore stand on the same foundation with every other production of motion. It indicates a moving power in A; but this inherent power feems to have no dependence on the motion of A: (See what is contained in n° 81. of the article Physics, and n° 67. of OPTICS of the Encycl.) We see there a motion produced in B without impulse, and taken from A, fimilar in every respect to every case of impulse; and we fee that the motion of A is necessary for producing such a motion in B as is observed in all cases of impulse, merely in order that the moving power, which is inherent in A, whether it be in rest or in motion, may act during a sufficient time. Our confidence in the communication of motion, in the case mentioned there, is derived entirely from experience, which informs us that A possesses a moving power totally different from impulse. Our belief of the impelling power of matter therefore does not necessarily flow from our intuitive knowledge of the perfeverance of matter, although it gives us the knowledge of this perfeverance. It is like a mathematical demonstration, a road to the discovery of the property of figure, but not the cause of that property. The impulsion of matter is merely a fact, like its gravitation, and we know no more of the one than of the other.

It is not a clearer perception, therefore, which has procured this preference of impulsion as the ultimate explanation of motion, and has given rife to all the foolish hypotheses of planetary vortices, ethers, animal spirits, nervous fluids, and many other crude contrivances for explaining the abstruce phenomena of nature.

Nor does it deferve any preference on account of its greater familiarity. Just the contrary: for one fact of undoubted impulse, we see millions where no impulse is observed. Consider the motion produced by the explofion of gunpowder. Where is the original impulse? Suppose the impulse of the first spark of fire to be immense, how comes it that a greater impulse is produced by a greater quantity of gunpowder, a greater quantity of quiescent matter? The ultimate impulse on the bullet should be less on this account. Here are plain exertions of moving powers, which are not reducible to impulse. Consider also the facts in animal motion. Reflect also, that there has been more motion, without any observed impulse, produced in the waters of a river since the beginning of the world, than by all the impulse that man has ever observed. Add to these, all the motions in magnetism, electricity, &c. Impulse is therefore a phenomenon which is comparatively rare.

impulse, without the action of forces at a distance? This appears to us very doubtful. Every one acquainted with Newton's discoveries in optics will grant, that the colours which appear between two object-glasses of long telescopes, when they are pressed together, demonstrate, that the glasses do not touch each other, except in the place where there is a black spot. It requires more than a thousand pounds to produce a square inch of this spot. Therefore every communication of motion between two pieces of glass, which can be produced by one of them striking the other, is produced without impulse, unless their mutual pressure has exceeded 1000 pounds on the square inch of the parts which act on each other. Nay, fince we fee that a black spot appears on the top of a foap bubble, in the middle of the coloured rings, we learn that there is a certain thickness at which light ceases to be visibly reslected; therefore the black fpot between the glaffes does not prove that they touch in that part; therefore we cannot fay that any force whatever can make them touch. The ultimate repulsion may be insuperable. If this be the case, the production of motion by impulse is, in every instance, like the production of motion between the magnets in no 81. of the article Physics in the Encycl. and is of the fame kind with the production of motion by gravity.

Therefore no explanation of gravitation can be de Intervening rived from any hypothesis whatever of intervening sluids. fluids mul-They only substitute millions of bodies for one, and still culties. leave the action e distanti the same difficulty as before. It is not in the least necessary that we shall be able to conceive how a particle of matter can be influenced by another at a distance; if we have discovered in every instance the precise degree and direction of the effect of this influence, we have made a most important addition to our knowledge of nature; and our success in the case of the power of gravity should make us assiduous in our endeavours to discover, from the phenomena, the laws which regulate the other actions e diffanti, which observation is daily finding out. A knowledge equally accurate of the law of magnetic and electric action may enable us to give theories of magnetism and electricity equally exact with the Newtonian theory of

Having, we hope, evinced the truth of this theory. by following out the investigations to which Newton was gradually led, we might proceed to confider, in order, the complicated and subordinate phenomena which depend on it. The lunar and planetary inequalities are the fubjects that naturally come first in our way; but they have already been explained in all the detail that this concife account will admit, as they occurred to Newton as tests of the truth of his conjecture. If the law be fuch as he fuspected, its consequences must be so and fo; if the celeftial motions do not agree with them, the law must be rejected. We shall not repeat any thing therefore on this head, but confine our observations to fuch applications of the theory of universal gravitation as newly discovered objects, or the improvement of astronomical observation and of fluxionary analysis, have enabled us to make fince the time of Newton.

The fubferviency of the eclipfes of Jupiter's fatellites to geography and navigation had occasioned their motions to be very carefully observed, ever since these Have we ever observed motion communicated by pure · uses of them were first suggested by Galileo, and their

mpulfe arely cberved.

the folar

fystem

theory is as far advanced as that of the primary planets. It has peculiar difficulties. Being very near to Jupiter, the great deviation of his figure from perfect sphericity makes the relation between their distances from his centre and their gravitations toward it vastly complicated. But this only excited the mathematicians fo much the more to improve their analysis; and they faw, in this little system of Jupiter and his attendants, an epitome of the folar fyftein, where the great rapidity of the motions must bring about in a short time every variety of configuration or relative position, and thus give us an example of those mutual disturbances of the primary planets, which require thousands of years for the discovery of their periods and limits. We have derived fome very remarkable and useful pieces of information Eternal du-from this investigation; and have been led to the difcovery of the eternal durability of the folar fystem, a thing which Newton greatly doubted of.

Mr Pound had observed long ago, that the irregularities of the three interior fatellites were repeated in a period of 427 days; and this observation is found to be

just to this day.

247 revolutions of the first occupy 437 d. 3h. 44' fecond 437 3 42 123 3 36 ÓΙ third 437 fourth 16 26 435 14

This naturally led mathematicians to examine their motions, and fee in what manner their relative politions or configurations, as they are called, corresponded to this period: and it is found, that the mean longitude of the first fatellite, minus thrice the mean longitude of the second, plus twice the mean longitude of the third, always made 180 degrees. This requires that the mean motion of the first, added to twice that of the third, shall be equal to thrice the mean motion of the second. This correspondence of the mean motions is of itself a fingular thing, and the odds against its probability seems infinitely great; and when we add to this the particular positions of the fatellites in any one moment, which is necessary for the above constant relation of their longitudes, the improbability of the coincidence, as a thing quite fortuitous, becomes infinitely greater. Doubts were first entertained of the coincidence, because it was not indeed accurate to a second. The refult of the investigation is curious. When we follow out the confequences of mutual gravitation, we find, that although neither the primitive motions of projection, nor the points of the orbit from which the fatellites were projected, were precisely such as suited these observed relations of their revolutions and their contemporaneous longitudes; yet, if they differed from them only by very minute quantities, the mutual gravitations of the fatellites would in time bring them into thofe positions, and those states of mean motion, that would induce the observed relations; and when they are once induced they will be continued for ever. There will indeed be a small equation, depending on the degree of unsuitableness of the first motions and positions; and this causes the whole system to oscillate, as it were a little, and but a very little way on each fide of this exact and permanent flate. The permanency of these relations will not be destroyed by any fecular equations arifing from external causes; such as the action of the fourth fatellite, or of the fun, or of a refisting medium;

because their mutual actions will distribute this equation as it did the original error.

This curious refult came into view only by degrees,. as analysis improved and the mathematicians were enabled to manage more complicated formulas, including more terms of the infinite feriefes that were employed to express the different quantities. It is to M. de la Grange that we are indebted for the completion of the discovery of the permanency of the system in a state very little different from what obtains in any period of its existence. Although this required all the knowledge and address of this great mathematician, in the management of the most complicated analysis, the evidence of its truth may be perceived by any person acquainted. with the mere elements of fluxionary geometry. The law of the composition of forces enables us to express every action of the mutual forces of the fun and planets by the fines and cofines of circular arches, which increase with an uniform motion, like the perpetual lapse of time. The nature of the circle shows, that the variations of the fines and cofines are proportional to the cofines and fines of the fame arches. The variations of their squares, cubes, or other powers, are proportional to the fines or cofines of the doubles or triples, or other multiples of the fame arches. Therefore fince the infinite serieses which express those actions of forces, and their variations, include only fines and cofines, with their powers and fluxions. it follows, that all accumulated forces, and variations of forces, and variations of variations, through infinite orders, are Itill expreffible by repeated fums of fines or cofines, corresponding to arches which are generated by going round and round the: circle. The analyst knows that these quantities become alternately positive and negative; and therefore, in whatever way they are compounded by addition of themselves, or their multiples, or both, we must always arrive at a period after which they will be repeated with all their intermediate variations. It may be extremely disficult, it may be impossible, in our present state of mathematical knowledge, to afcertain all those periods. It has required all the efforts of all the geniuses of Europe to manage the formulas which include terms containing the fourth and fifth powers of the eccentricities of the planetary orbits. Therefore the periods which we have already determined, and the limits to which the inequalities expressed by fecular equations arrive, are still fubjected to smaller corrections of incomparably longer periods, which arise from the terms neglected in our formulas. But the correction arising from any neclected term has a period and a limit; and thus it will happen that the fystem works itself into a state of permanency, containing many intervening apparent anomalies. The elliptical motion of the earth contains an anomaly or deviation from uniform circular motion; the action of Jupiter produces a deviation from this elliptical motion, which has a period depending on the configuration of the three bodies; Saturn introduces a deviation from this motion, which has also a period; and so on.

There is another accurate adjustment of motions which has attracted attention, as a thing in the highest degree improbable, in events wholly independent on each other. This is the exact coincidence of the period of the moon's revolution round the earth with that of her rotation round her own axis. The ellipticity or oval shape of the moon differs so insensibly from a sphere,

that if the original rotation had differed confiderably from the period of revolution, the pendular tendency to the earth could never have operated a change: but if the difference between those two motions was fo small, that the pendular tendency to the line joining the centres of the earth and moon was able to overcome it after fome time, the pole of the lunar spheroid would deviate a little from the line joining the earth and moon, and then be brought back to it with an accelerated motion; would pass it as far on the other side, and then return again, vibrating perpetually to each fide of the mean polition of the radius vector. The extent of this vibration would depend on the original difference between the motion of rotation and the mean motion of This difference must have been very small, revolution. because this pendular vibration is not sensible from the earth. The observed LIBRATION of the moon is precifely what arises from the inequality of her orbital motion. For the same reasons, the effects of the secular equations of the moon (which would, in the course of ages, have brought her whole furface into our view, had her rotation been strictly uniform) are counteracted by her pendular tendency, which has a force sufficient to alter her rotation by nearly the same slow and infensible charges that obtain in her mean motions. The fame causes also preserve the nodes of her equator and of her orbit in the same points of the ecliptic. The complete demonstration of this is perhaps the most delicate and elegant specimen that has been given of the modern analysis. We owe it to M. de la Grange: and he makes it appear that the figure of the moon is not that which a fluid fphere would acquire by its gravitation to the earth; it must be the effect of a more confiderable ellipticity, or internal inequality of denfity.

Depends on

This permanency of the fystem, within very narrow the law of limits of deviation from its present state, depends entirely on the law of planetary deflection. Had it been directly or inverfely as the distance, the deviations would have been such as to have quickly rendered it wholly unfit for its present purposes. They would have been very great, had the planetary orbits differed much from circles; nay, had some of them moved in the opposite direction. The felection of this law, and this form of the orbits, strikes the mind of a Newton, and indeed any heart possessed of sensibility to moral or intellectual excellence, as a mark of wildom prompted by benevolence. But De la Place and others, infected with the Theophobia Gallica engendered by our licentious defires, are eager to point it out as a mark of fatalism. They fay, that it is effential to all qualities that are diffused from a centre to diminish in the inverse duplicate ratio of the distance. But this is false, and very false: it is a mere geometrical conception. We indeed tay, that the denfity of illumination decreases in this proportion; but who fays that this is a quality? Whether it be confidered as the emission of luminous corpuscles, or an undulation of an elastic sluid, it is not a quality emanating from a centre: and even in this estimation, it feems gratuitous, whether we shall consider the bale of the luminous pyramid, or its whole contents, as the expression of the quantity. Nay, if all qualities raust di-minish at this rate, all action e distanti must do the same; for when the distances bear any great proportion to the diameters of the particles, their action deviates infenf bly from this law, and is perceived only by the accumula-

tion of its effects after a long time. It is only thus that the effects of the oblate figure of Jupiter are perceived in the motion of his fatellites. The boafted found philosophy which sees fatal necessity where the most successful fludents of nature saw moral excellence, has derived very little credit or title to the name of wifdom, by letting loofe all those propensities of the human heart which are effentially destructive of social happiness. Thete propenfities were always known to lurk in the Andevinheart of man; and those furely were the wiest who la-ces the wifboured to keep them in check by the influence of moral dem of the principles, and particularly by cheriching that It's principles, and particularly by cherishing that disposition of the human heart which prompts us to fee contrivance wherever we fee nice and refined adjustment of means to ends; and, from the admirable beauty of the folar fystem, to cry out,

"These are thy glorious works, Parent of good!!

" Almighty, thine this universal frame,

"Thus wond'rous fair; thyself how wond'rous then! " Unspeakable, who fitt'st above these heavens,

"To us invisible, or dimly seen

" In these thy lowest works; yet these declare

" Thy goodness beyond thought, and power divine." Par. Loft, b. v.

"But wandering oft, with brute unconscious gaze, " Man marks not THEE, marks not the mighty hand

"That, ever bufy, wheels the filent spheres."

The most important addition (in a philosophical view) that has been made to astronomical science since the discovery of the aberration of light and the nutation of the earth's axis, is that of the rotation of Saturn's ring. The ring itself is an object quite fingular; and when it Saturn's was discovered that all the bodies which had any imme-ring. diate connection with a planet were heavy, or gravitated toward that planet, it became an interesting queftion, what was the nature of this ring? what supported this immense arch of heavy matter without its resting on the planet? what maintains it in perpetual concentricity with the body of Saturn, and maintains its furface in one invariable position?

The theory of universal gravitation tells us what. things are possible in the solar system; and our conjectures about the nature of this ring must always be regulated by the circumstance of its gravitation to the planet. Philosophers had at first supposed it to be a luminous atmosphere, thrown out into that form by the great centrifugal force arising from a rotation: but its well defined edge, and, in particular, its being two very narrow rings, extremely near each other, yet perfectly separate, rendered this opinion of its constitution more improbable.

Dr Herschel's discovery of brighter spots on its sur-Discovery face, and that those spots were permanent during the of Dr Herwhole time of his observation, seems to make it more schel relaprobable that the parts of the ring have a folid connecting to its tion. Mr Herschel has discovered, by the help of those spots, that the ring turns round its axis, and that this axis is also the axis of Saturn's rotation. The time of rotation is 10h. 321'. But the other circumstances are not narrated with the precision sufficient for an accurate comparison with the theory of gravity He informs us, that the radii of the four edges of the ring are 590, 751, 774, 830, of a certain scale, and that the

angle subtended by the ring at the mean distance from tual action, and the action of the sun, and their own irthe earth is $46\frac{2}{3}$ ". Therefore its elongation is $23\frac{3}{3}$ ". The elongation of the second Cashinian satellite is 56', and its revolution is 2d. 17h. 44'. This should give, by the third law of Kepler, 17h. 10' for the revolution of the outer edge of the ring, or rather of an atom of that edge, in order that it may maintain itself in equilibrio. The fame calculation applied to the outer edge of the inner ring gives about 13 h. 36'; and we obtain 11h. 16' for the inner edge of this ring. Such varieties are inconfishent with the permanent appearance of a spot. We may suppose the ring to be a luminous stuid or vapour, each particle of which maintains its fituation by the law of planetary revolution. In such a state, it would confift of concentric frata, revolving more flowly as they were more remote from the planet, like the concentric strata of a vortex, and therefore having a relative motion incompatible with the permanency of any spot. Besides, the rotation observed by Herschel is too rapid even for the innermost part of the ring. We think therefore that it confifts of cohering matter, and of confiderable tenacity, at least equal to that of a very clammy fluid, fuch as melted glass.

We can tell the figure which a fluid ring must have, so that it may maintain its form by the mutual gravitation of its particles to each other, and their gravitation to the planet. Suppose it cut by a meridian. It may be in equilibrio if the section is an ellipse, of which the longer axis is directed to the centre of the planet, and very small in comparison with its distance from the centre of the planet, and having the revolution of its middle round Saturn, fuch as agrees with the Keplerean law. These circumstances are not very consistent with the dimensions of Saturn's inner ring. The distance between the middle of its breadth and the centre of Saturn is 670, and its breadth is 161', nearly one-fourth of the distance from the centre of Saturn. De la Place fays, that the revolution of the inner ring observed by Herschel is very nearly that required by Kepler's law: but we cannot fee the grounds of this affertion. The above comparisons with the second Cassinian satellite shows the contrary. 'I'he elongation of that fatellite is taken from Bradley's observations, as is also its periodic time. A ring of detached particles revolving in 10h. 321 must be of much smaller diameter than even the inner edge of Saturn's ring. Indeed, the quantity of matter in it might be fuch as to increase the gravitation confiderably; but this would be feen by its diffurbing the feventh and fixth fatellites, which are exceedingly near it. We cannot help thinking therefore that it confilts of matter which has very confiderable tenacity. An equatorial zone of matter, tenacious like melted glais, and whirled brifkly round, might be thrown off, and, retaining its great velocity, would firetch out while whirling, enlarging in diameter and diminishing in thickness or breadth, or both, till the centrifugal force was balanced by the united force of gravity and tenacity. We find that the equilibrium will not be fenfibly diflurbed by confiderable deviations, fuch as unequal breadth, or even want of flatness. Such inequalities appear on this ring at the time of its disparition, when its edge is turned to the fun or to us. The appearances of its different fides are then confiderably different.

regularities: but there will be a certain position which they have a tendency to maintain, and to which they will be brought back, after deviating from it, by the ellipticity of Saturn, which is very great. The fun will occasion a nutation of Saturn's axis and a preceffion of his equinoxes, and this will drag along with it both the rings and the neighbouring fatellites.

The atmosphere which furrounds a whirling planet cannot have all its parts circulating according to the third law of Kepler. The mutual attrition of the planet, and of the different strata, arising from their different velocities, must accelerate the slowly moving strata, and retard the rapid, till all acquire a velocity proportional to their distance from the axis of rotation; and this will be fuch that the momentum of rotation of the planet and its atmosphere remains always the same. It will fwell out at the equator, and fink at the poles, till the centrifugal force at the equator balances the weight of a fuperficial particle. The greatest ratio which the equatorial diameter can acquire to the polar axis is that of four to three, unless a cohesive force keeps the particles united, fo that it constitutes a liquid, and not an elastic sluid like air; and an elastic sluid cannot form an atmosphere bounded in its dimensions, unless there be a certain rarity which takes away all classicity. If the equator swells beyond the dimension which makes the gravitation balance the centrifugal force, it must immediately dissipate.

If we suppose that the atmosphere has extended to this limit, and then condenfes by cold, or any chemical or other cause different from gravity, its rotation neceffarily augments, preferring its former momentum, and the limit will approach the axis; because a greater velocity produces a greater centrifugal force, and requires a greater gravitation to balance it. Such an atmosphere And origin. may therefore defert, in succession, zoncs of its own matter in the plane of its equator, and leave them revolving in the form of rings. It is not unlikely that the rings of Saturn may have been furnished in this very way; and the zones, having acquired a common velocity in their different strata, will preserve it; and they are fusceptible of irregularities arising from local causes at the time of their feparation, which may afford permanent spots.

We think that the rotation of Saturn's ring affords it may furfome hopes of deciding a very important question about nish time the nature of light. If light be the propagation of means of elastic undulations, its velocity depends entirely on the the nature elasticity and density of the sluid; but if it be the emil- of light. fion of corpufcles, their velocity may be affected by other causes. The velocity of Saturn's ring is $\frac{5}{9}$? of that of the earth in its orbit, and therefore about TOOOO of the velocity of light. The western extremity (to us in the northern regions) is moving from us, and the eastern is moving toward us. If light, by which we see it, be reflected like an elastic ball from an elastic body, there will be an excess in the velocity of the light by which we see the eastern limb above the velocity of the light by which we see the western limb. This excess will be 1500 of the mean velocity of light. This should be discovered by a difference in the refraction of the two lights. It an acromatic prism could be made to Such a ring or rings must have an oscillatory motion refract fourteen degrees, and if Saturn be viewed thro' gound the centre of Saturn, in confequence of their mu- a telescope with this prism placed before it, there should

Its probable confifrency

be a change of shape amounting to fixteen seconds; if the axis of the prism be parallel to the longer axis of the ring, it will diffort it prodigiously, and give it an oblique position.

A similar effect will be produced by placing the prism between the eye-glass and the image in the focus

of the object glass.

Our expectation is founded on this unquestionable principle in dynamics, that when a particle of light passes through the active stratum of a transparent body which refracts light toward the perpendicular, the addition made to the square of its velocity by the refracting forces is equal to the square of the velocity which those forces would communicate to a particle at rest on the furface of this refracting stratum of the transparent body. Therefore if the velocity of the incident light be increased, the ratio of the fine of incidence to the fine of refraction will be diminished. It is consonant to common fense, that when the incident light has a greater velocity, it passes more rapidly through the attracting stratum, and a smaller addition is made to the velocity. When the velocity of the incident light is 10000 times greater than that of the earth's annual motion, the fine of incidence is to the fine of refraction in glass as 20 to 31, or as 10000 to 15500. If this be increased 1,000, making it 10004, the ratio will be that of 10004 to 15502,62, or of 10000 to 15496,4. The difference between the refractions of the light from the eastern and western extremities of the ring will be, to all sense, the same, if the velocity of the one be diminished to 9998, and the other increased to 10002.

We may just add here, by the way, that the action of another body may confiderably change the constitution of this atmosphere. Thus, supposing that the afon why moon had originally an atmosphere, the limit will be mosphere that distance from the moon where the centrifugal force, arifing from the moon's rotation, added to the gravitation to the earth, balances the gravitation to the moon. If the moon be $\frac{1}{50}$ th of the earth, this limit will be about the of the moon's distance from the earth. If at this distance the elasticity of the atmosphere is not annihilated by its rarefaction, it will be all taken off by the earth, and accumulate round it. This may be the reason why we see no atmosphere about

the moon.

What has been faid in the article TIDE (Encycl.), will explain the trade winds on the earth and in Jupiter and Saturn. On the earth they are increased by the expansion of the air by heat. This causes it to rife

in the parts warmed by the fun, and flow off toward the poles, where it is again cooled and condenfed. The under stratum of colder and denser air is continually flowing in from the poles. This having less velocity of circulation than the equatorial parts of the earth, must have a relative motion contrary to that of the earth, or from east to west, and this must augment the current produced by gravitation.

THUS we fee that all the mechanical phenomena of the folar fystem, whether relating to the revolutions round the various centres of gravitation, or to the figure of the planets and the ofcillations of the fluids which cover them, or to the rotations round their respective axes-are necessary consequences of one simple principle of a gravitation in every particle, decreasing in the reciprocal duplicate ratio of the distance. We see that All the methis, combined with a primitive projection, will produce chanical every motion that we observe. It was not necessary, as phenome-Copernicus imagined, to impress three motions on the na of the earth; one, by which it was made to revolve round the tem flow fun; a fecond, caufing it to turn round an axis inclined from one to that of its orbit; and a third, by which this axis de-fimple prinscribed that conic surface which forms the precession of ciple. the equinoxes. One impulse, not passing through the centre of the earth, nor in the plane of the ecliptic, will produce the two first motions, and the protuberant matter produced by the rotation will generate the third motion, by the tendency of its parts to the other heavenly bodies. Without this principle, the elliptic motion of the planets and comets, their various inequalities, fecular or periodical, those of the moen and of the fatellites of Jupiter, the precession of the equinoxes, the nutation of the earth's axis, the figure of the earth, the undulations of its ocean-all would have been imperfectly known, as matters of fact, wholly different from each other, and folitary and unconnected. It is truly deferving admiration, that fuch an immense variety of important phenomena flow fo palpably from one principle, of fuch fimplicity, and fuch universality, that no phenomenon is now left out unexplained, and predicted with a certainty almost equal to actual observation.

fymme-

try.

70 robable

n + 2 order, when it is a parabola whose ordinate is al-Aure iqua, ways as the *n* power of the base. The asymptote is oblique to the base, when the ratio of the first fluxion of the ordinate to the fluxion of the base approaches to an affignable ratio, as its limit; but it is parallel to the base, or eoincides with it, when this limit is not assign-

ATTAR OF ROSES. See Roses, Otter of, both in

the Encyclopædia and in this Supplement.

AVANT Foss, or Ditch of the Counterfearp, in fortification, is a wet ditch furrounding the counterfearp on the outer fide, next to the country, at the foot of the glacis. It would not be proper to have fuch a ditch if it could be laid dry, as it would then ferve as a lodgment for the enemy.
AUBIGNE. See STUART in this Supplement.

AUMIL, in Bengal, a native collector or manager

of a diffrict on the part of government.

AUTENIQUA, a large and heautiful country in Africa, lying to the east of the Cape of Good Hope, and inhabited, part of it, by Dutch colonitts. The word Auteniqua fignifies, in the Hottentot language, " a man loaded with honey;" a name which is not improperly given to the country, fince, as you enter it from the Cape, you cannot proceed a step without seeing a thousand swarms of bees. The flowers on which they feed fpring up in myriads; and your attention is engaged, and your course suspended, by the mixed odours which exhale from them, by their colours and variety, and by the pure cool air which you breathe. Nature has made these enchanting regions like fairy land. The calyxes of all the flowers abound with excellent juices, from which the bees extract the honey that they everywhere deposit in hollow rocks and trees.

This country was visited in 1782 by M. Vaillant, who calls it the most delightful region in the universe; and fays, that, as he approached it, he beheld, from the top of a very high mountain, an immense valley, adorned with agreeable hills, variegated in an infinite number of shapes, and extending in an undulating manner as far as the fea; whild enamelled meads, and the most beautiful pastures, still added to the magnificent scene. It abounds with small rivulets, which, slowing down from the mountains, run into the fea through an hundred different channels. The water of these rivulets has the colour of Madeira wine, and a ferruginous tafte; but our traveller did not examine whether this tafte and colour proceed from their flowing through forne mine in their passage, or from the roots and leaves of trees

which they carry along with them.

The whole of Auteniqua, from the chain of mountains which divides it from the country of that race of Hottentots called Gonaquas to the fee, is inhabited by feveral planters, who rear a number of cattle, make butter, cut down timber, and collect honey; all of which they transport to the Cape: but it appears that they make not the most of their situation. " Can it be believed (fays M Vaillant), that the directors of the Company, for their own use, should order ships to be sent every year from Amsterdam, loaded with planks and boards of every kind, whilst in this country there are immense forests, and the most beautiful trees in the world? This abfurdity, however, is not at all aftonishing. The Company gratuitously furnishes the gover- prey. He had on one occasion killed two buffaloes,

axis perpendicular to the base; and, in general, of the nor and all the officers with whatever wood they have Autenique, occasion for; and it is delivered to them at their houses without any expence. The governor therefore has no personal interest to extend his views to this part of the administration, and to abolish an abuse so prejudicial to the colony."

But the colonists themselves must be a very indolent and stupid kind of people; since, if our traveller deferves credit, they neglect advantages with which the perfonal interest of the governor cannot possibly interfere. "I was filled with indignation (fays M. Vaillant; to fee people, who have wood within their reach, employ it in commerce, and not have the courage to build for themselves habitable houses. They live in wretched hovels, conftructed of wicker-work, daubed over with clay; the skin of a buffalo, fixed at the four corners to as many flakes, ferves them for a bed; and the door, which is at the fame time a window, is shut by a mat; while two or three mutilated chairs, a few pieces of plank, a kind of table, and a pitiful box of two feet Iquare, form all the furniture of these colonial habitations. Thus is the picture of the most profound mifery contrasted with the charms of this terrestrial paradife; for the beauties of these regions extend even beyond Auteniqua. The people, however, though their houses be bad, live well. They have game and falt water fish in abundance; and enjoy exclusively, over all the other cantons of these colonies, the advantage of having, for the whole year without interruption, vegetables of every kind in their gardens. For this they are indebted to the excellence of the foil, and to its being naturally watered by finall ftreams, which crofs each other in a thousand different directions, and, as one may fay, lay the four feafons under contribution to fertilize duteniqua. These streams, which frequently overflow their banks, but never dry up, proceed from a caufe well known; the high mountains towards the calt, which are covered with forests, stop the clouds and the fogs carried from the fea, and this occasions very abundant rains."

In these mountainous regions, which, as well as the plain, our author comprehends under the denomination of Auteniqua, there are multitudes of elephants, buffaloes, panthers, hyenas, and antelopes of every species and all these animals are hunted and killed by the natives, as well for food as for the protection of their flocks and herds from fuch of them as are beafts of prey. Our author has eaten the flesh of every one of them except the hyena; and declares, that the foot of an elephant, baked after the Hottentot manner, is one of the most delicious morfels that he ever tasted. He gives directions for hunting them all; but warns his readers from attacking elephants when he finds them in droves, for then, he fays, they are invincible. He even thinks it exceedingly dangerous for one man, however well armed, to attack a fingle elephant in the plain. The buffalo he describes, contrary to most other travellers, as a timid animal, which never refitts till his fituation becomes desperate; and he thinks that there would be no difficulty in training him, if caught when a calf,

to the yoke like the bullocks of Europe.

The kites and vultures of this country, our traveller reprefents as in the highest degree voracious and fierce, infomuch that it is hardly possible to fright them from their

steniqua, which he ordered to be cut into very small pieces, that dred groves, which are naturally variegated, and each Auteniqua. they might be more easily falted, and exposed afterwards to the air and the fun. His waggons, as well as the bushes and trees which surrounded him and his people, were loaded with the bloody fragments of these two animals, and they had begun their operation of falting; but on a sudden, while they were not expecting it, they found themselves attacked by slights of kites and vultures, which, without exhibiting the least fymptoms of fear, perched in the midst of them. The kites were above all the most impudent. They seized upon the morfels of flesh, and even contended furiously with his people. "When they had each carried away (fays he) a pretty large piece, they retired to fome branch, at the distance of ten paces from us, and devoured it before our eyes. Though we fired our fusees they were not frightened, but returned inceffantly to the charge; fo that finding our powder wasted in vain, we resolved to keep them off with large poles until our provisions should be quite dry. This manœuvre, which for a long time haraffed my people, did not prevent us from being plundered without mercy; but had we not employed it, nothing would have remained to us of our two buffaloes."

This battle with the kites took place on the confines of the Dutch fettlements; but when M. Vaillant had with difficulty passed over the mountains which bound them, the prospects became more magnificent, the foil feemed to be more fruitful and rich, nature appeared to be more majestic and grand, and the lofty mountains presented on all sides more charming and delightful points of view than any that he had ever before met with. These scenes, contrasted with the dry and parched fields of the Cape, made him exclaim, he fays, in ecstacy, "What! shall these superb regions be eternally inhabited by tygers and lions? What speculator, with the fordid view only of establishing a kind of centre for commerce, could have preferred the stormy Table Bay to the numberless roads and commodious harbours which are to be found on the eastern coasts of Africa? Thus (continues he) was I reflecting within myself, whilft I was climbing the mountain, and forming vain wishes for the conquest of this beautiful country, which the indolent policy of the European nations will perhaps never gratify."

If his description of its beauties and fertility be not greatly exaggerated, it is indeed wonderful that either the Dutch or some other maritime power of Europe has not long ago taken possession of it. After he had passed the mountain, one could not, he says, choose a more agreeable or advantageous spot than that upon which he then was for establishing a thriving colony. The sea advances through an opening of about a thousand paces in breadth, and penetrates into the country to the distance of more than two leagues and a half. The bason which it forms is more than a league in extent (he does not fay whether in breadth or in circumference); and the whole coast, both on the right and the left, is bordered with rocks, which intercept all communication with it. The land is watered by limpid and refreshing ftreams, which flow down on all fides from the eaftern mountains; and these mountains, crowned with majestic woods, extending as far as the bason, and winding round it with a number of finuofities, exhibit a hun-

SUPPL. VOL. I. Part I.

more agreeable than another.

The author proceeding forwards about two days journey, arrived at a bay known to navigators by the name of the Bay of Agoa, but called by the colonists Blettenberg's Bay, from its having been visited some time before by a Governor Blettenberg, who ordered his name, together with the year and day of his arrival, to be engraven on a stone column. This bay is a little beyond the limits of the country called Auteniqua; but it is not foreign from the purpose of this article to infert in this place our traveller's account of it, and of the country around it.

The bay itself, he fays, is very spacious, and has a fufficient depth of water for the largest vessels. The anchoring ground is fure, and boats can fail to a beautiful part of the shore, which is not confined by the rocks, as they are all there detached from one another. By advancing a league along the coast, the crews would arrive at the mouth of a confiderable river called the Queur-Boom, where they would find water. Refreshments might be procured from the inhabitants of the environs; and the bay would supply them with excellent fish, with which it abounds.

This bay is one of those places where government might establish warehouses and repositories for timber; and it is for this reason that we have introduced it to notice in this article. The forests around it, says M. Vaillant, are everywhere magnificent, and the trees could be more easily cut down than anywhere else; for it is not to fleep mountains that one must go for wood, as at Auteniqua; it is here ready at hand; and during the fine monfoon might be transported to the Cape with little trouble and no risk. The inexhaustible and fertile lands in the neighbourhood of the bay, if once cultivated, would produce abundant crops, and draw together a great number of intelligent planters, on account of the ready communication which they would have with the Cape. In a word, the Company, continues he, have nothing to do fo much for their own interest as to form here a proper establishment. To the general profits of fuch an inflitution, would be added those of individuals, which could not fail to be of great import-They might, for example, cut down a certain tree called flinking wood, and export it to Europe, where it would undoubtedly be foon preferred to maliogany and every other kind of wood employed by cabinet makers.

The Hottentots, who in scattered kraals inhabit this delightful country, our author describes as a faithful. gentle, and rather timid race. He affirms, that they have no religious impressions whatever, nor any notion of superior powers who govern the world. But this, if not a wilful falfehood dictated by the philosophy of France, is probably a mistake arising from his scanty knowledge of their language, and total ignorance of the meaning of their religious ceremonies. His great mafler, as well as the mafter of his feet, Lucretius, might have taught him, that fear, if not a better principle, will generate the notion of superior beings in the minds of of favages; and from fear, by his own account, the inhabitants of Auteniqua are far from being free. He likewise affirms, and seems to consider it as much to their credit, that this race of gentle beings, so far from

Automa- being a prey to the passion of jealousy (as other travelton. lers have represented the Hottentots in general), are so obliging, as to lend their wives to travellers who vifit them, and that they actually accommodated his Hottentots in this way. Auteniqua, as laid down in M. Vaillant's map, lies between 33° 30' and 34° 50' of fouth latitude, and between 20° and 23° 40' of east longitude; and his rout through the country was from fouth-west

to north-east, or nearly so.

AUTOMATON. Under this title and that of Androides full credit was allowed in the Encyclopadia Britannica to the story of M. de Kempell's mechanical chefs-player, and a detail at some length was given of the feats of that figure, as well as of some other surprifing automata. No man more readily admits the powers of the skilful mechanician than the writer of this short article; but having many years ago detected the impofition which was practifed on the public in some parts of Scotland by a circumferaneous mountebank, who exhibited a figure apparently capable of writing a certain number of words, he has ever fince suspected imposture in all automata which appear to have the power of varying their motions according to circumstances. With respect to the chefs player, there is now sufficient evidence that his fuspicions were well founded.

In the description of this figure (Encycl. Vol. I. p. 787.), "it is faid, that the automaton could not play unless M. de Kempell or his substitute was near it to direct its moves. A fmall box during the game was frequently confulted by the exhibiter; and herein confished the fecret, which he faid he could in a moment communicate." The fecret was indeed fimple: "A well taught boy, very thin and small of his age, was concealed in this box almost immediately under the chefs-board, and agitated the whole machine." This we learn from Thomas Collinson, Esq; who was let in-

to the fecret at Dresden by a gentleman of rank and ta- Automa. lents, named Joseph Freidrick Freyhere, by whom the vitality and foul of the chefs-playing figure had fome time before been completely discovered. Mr Collinson, finding that Dr Hutton had given the fame credit with us to the reality of mechanical chefs-playing, undeceived his friend, by communicating the discovery of Freyhere in a letter, which the Doctor has with great propriety published in the Addenda to his Mathematical Dictionary. Mr Collinson adds, and we doubt not with truth, that, "even after this abatement of its being firifly an automaton, much ingenuity remains to the contriver." This was in some degree true of the mechanism of the writing figure, of which the compiler of this article detected the bungling imposture of the two exhibiters. The figure itself, with all the principles of its motion, were very ingeniously constructed; but the two men who exhibited it were ignorant and aukward, and could not conceal from a fcrutinizing eye, that the automaton wrote fometimes well and fometimes ill, and never wrote at all when they were both prefent to the company. It was by infifting upon feeing them both together, and threatening to expose the cheat to the whole town, that the prefent writer prevailed upon him who appeared to be the principal exhibiter, to confess in private that his companion was concealed behind a fcreen, and to flow how, from thence, he directed the movements of the figure.

CONJUGATE AXIS, or Second Axis, in the ellipse and hyperbola, is the diameter passing through the centre, and perpendicular to the transverse axis; and is the

shortest of all the conjugate diameters.

Transverse Axis, in the ellipse and hyperbola, is the diameter passing through the two foci and the two principal vertices of the figure. In the hyperbola it is the shortest diameter, but in the ellipse it is the longest.

B.

BAHRDT (Dr Carl Friedirich) was fo deeply concerned in a combination of philosophers formed, as they faid, for the advancement of science and virtue, that an account of his life must be interesting, if it were only to show the effects of this philosophic culture on his own morals. We trust therefore that our readers will be pleafed, perhaps improved, by the following narrative, taken from documents the most authentic, by a * Sec Pro- man * whose communications on other subjects do cre-

fessor Robi dit to this volume.

fon of Edin-Carl Friedirich Bahrdt was, in 1741, born at Leip-Profs of a fig, where his father, then a parish minister, and after-Gonspiracy wards professor of theology, died in 1775. It is natu-against all ral to suppose that such a parent would be at due pains the Religions to instil into the mind of his fon the principles of piety, and Govern-virtue, and patriotifm, which is indeed a branch of virtue; but if so, he lived to see that his labour had been

in vain. While yet at college, where the course of his Bahrdt. fludies was calculated to fit him for the important office of preaching the gospel, the young man enlisted as a hussar in the Prussian service; but being bought off, he returned to the university, where, in 1761, he was admitted to the degree of M. A. Soon afterwards he became catechift in his father's church, was a popular preacher, and in 1765 published sermons, and some controverfial writings, which evinced that he poffeffed both learning and genius. Neither learning nor genius, however, nor both united, could attach him to the cause of virtue, or make him observe even the common rules of decorum; for immediately after this publication he began to indulge in conviviality, and to give fcope to his refentments in anonymous pasquinades, in the highest degree bitter and offensive. From the shafts of his malice no person was safe. Professors, magistrates,

Bahrdt. and clergyman, had indeed his chief notice; but he condescended occasionally to attack students, and spared not even his own comrades or his friends.

Whilst he was thus labouring to make enemies of all to whom he was known, unfortunately, for his own character, his temperament was what the atomical philosophers (who can explain every thing by ethers and vibrations) call sanguine; and he was, as he himfelf ac. knowledged, a passionate admirer of the ladies. Coming home from his midnight revels, he frequently met in his way a young girl neatly dreffed in a rofe coloured filk jacket and train, and a coftly fable bonnet; and one evening, after having, as he fays, indulged freely in some old Rhenish, he saw her home to her lodgings. Some time after this interview, the mistress of the house (a Madam Godschusky) came into his room, and faid that the poor maiden whom he had debauched was pregnant. This was a misfortune which he could not help; but as it would ruin his character if known, he gave to the old lady a bond for 200 dahlers (about L.40 sterling), to be paid by inflalments of twenty five, to keep the matter fecret. "The girl (he fays) was fenfible and good; and as her conversation, for which he had already paid, was agreeable, he did not discontinue his acquaintance."

It could not be supposed that such visits, by a clergyman, would pass unobserved, however cautiously made, in the midst of a town, of which the inhabitants had been the indifcriminate objects of his fatire; and he could hardly be furprifed when told by a friend, that one Bel, a magistrate whom he had lampooned, was acquainted with the whole affair, and would bring it into a court of justice, unless the bond was immediately

This bond was the only evidence which could be produced against Bahrdt, but it was sufficient to blast his character in Leipfig, and must therefore by any means be removed out of the way. To accomplish this, however, was a matter of some difficulty; for neither he nor his friend could raife the money. In this dilemma they fell upon a contrivance worthy of themselves. They invited Madam Godschusky to meet them in another house to receive the 200 dahlers due to her by Bahrdt; but when she was ushered into the room, and found no person waiting for her but Bahrdt's friend, she could not be prevailed upon to produce the bond till the money should be put into her hands, together with a prefent to herfelf. The Gentleman tried to intimidate her. He drew his fword; showed her how men fence; made pushes at the wall and then at her: but finding that she could not be frightened out of her fenses, he threw away his fword, and endeavoured to take the bond from her by force. It was fome time before he prevailed; but at last getting the paper out of her pocket, he tore it in pieces, opened the door of a closet in which Bahrdt was concealed, and faid, "There, you b ---; there is the honourable fellow whom you and your whore have bullied; but it is with me you have now to do, and you know that I can bring you to the gallows."

Bahrdt, from whose memoirs of himself this story is taken, admits that there was a great fquabble on the occasion; but he went home, comforting himself with the belief that he should now have no farther trouble from Madam Godschusky or her girl. He chanced, however, to be mistaken. The magistrate Bel had some

how been made acquainted with this nefarious transac- Bahrdt. tion, and brought it into court on the day that our hero was to make some very reverend appearance at church. The case of Bahrdt was now hopeless; for after some unsuccessful attempts of his poor father to fave him, he was obliged to give in his gown and band,

and to quit Leipfig.

To a parent the public difgrace of a child is one of the feverest calamities to which human nature is liable; but for this calamity the father of Bahrdt must have been long prepared, as his fon appears to have been remarkably undutiful. Of this we have one memorable instance recorded by himself. His father, he fays, was fevere, and his own temperament hasty, fo that he sometimes forgot himself. "One day (continues he) I laid a loaded pistol on the table, and told him that he should meet with that if he went on fo; but I was then only SEVENTEEN!"

On his being obliged to leave the place of his nativity, the friends of Bahrdt, and in particular Semler, an eminent theological writer, who had formed a very favourable opinion of his talents, were affiduous in their endeavours to procure an establishment for him elsewhere; but his high opinion of himself, his impetuous and precipitant temper, and that fatirical habit which he had fo freely indulged in his outfet in life, made their endeavours long ineffectual. At last he got a professorship at Erlangen, then at Erfurth, and in 1771 at Giessen. But in each of these places he was no fooner fettled than he got into difputes with his colleagues and with the established church; for he was a strenuous partizan of the innovations then attempted to be made in the doctrines of Christianity. In his publications, which were generally anonymous, he did not trust to rational discussion alone, but had recourse to ridicule and perfonal anecdotes, and indulged in the most cutting farcasms and gross scurrility.

His love for convivial company continuing, his income was infufficient for the eraving demand. Finding therefore that anecdote and flander always procured readers, and possessing a wonderful activity and facility in writing, he never ceased from publishing lampoons and satires, in which he fpared neither friends nor foes. But it was impossible to prevent these publications from being traced to their author; and his avowed theological writings being fuch as could not be suffered in a professor of divinity, the host of enemies which he had been at so much pains to raise against himself, were furnished with fufficient grounds for subjecting his conduct to legal cognizance; even the very students at Giessen were

shocked at some of his liberties.

The consequence of all this was, that, after much wrangling in the church judicatories, he was just about to be difmiffed from his professorship, when he got an invitation to Marschlins in Switzerland to superintend an academy.

To Marschlins he went about the year 1776, and began his new career by forming the feminary after the model of an academy which had fome time before been fet up in the principality of Anhalt Dessau by one Bafedow, a man of talents and learning, who gave to it the appellation of PHILANTHROPINE. The plan of this academy was very different from those of the universities; for its author professed to consider languages, sciences, and the ornamental exercises, as mere accessoof mankind and of virtue, by a course of moral education certainly specious, and apparently unexceptionable. To make this novel institution the more extensively useful, the rules by which the education was to be conducted were framed in fuch a manner as, it was thought, would remove from the minds of Catholics, Lutherans, and Calvinists, all uneafiness respecting the faith of their children, as it related to those particular tenets which separated them into different communions. It was even proposed to banish from the philanthropine all positive religion whatever, and to instruct the youth educated there in the principles only of natural, or, as it was called, philosophical religion.

This plan was peculiarly suited to Bahrdt's taste, because it left him at liberty to introduce into his academy any fystem of religious or irreligious opinions that he pleased; a liberty of which he resolved to avail himself, and, though now a doctor in theology, to outstrip; in licentiousness, even the founder of the philanthropine, who was not in orders. By meditating on the workings of his own mind, he had by this time formed his theory of human nature, which was indeed very simple. "The leading propenfities of the human mind (he fays) are three; instinctive liberty, instinctive activity, and instinctive love." By these expressions we suppose he means, "innate love of liberty, instinct prompting to action, and the fexual appetite:" and he immediately adds, that " if a man is obstructed in the gratification of any of these propensities, he suffers an injury. The business therefore of a good education is to teach us how they are to be gratified in the highest degree"

That fuch an education would be approved of by the uncorrupted natives of Switzerland was hardly to be expected; and Bahrdt foon found his tituation at Maischlins as uncomfortable as it had been at Giessen. "The Grifons (he fays) were a strong instance of the immense importance of education. They knew nothing but their handicrafts; and their minds were as coarse as their persons." He quarrelled with them all, and was obliged to abfcond after lying fome time in prison.

From Marschlins he went to Durkheim, a town in the palatinate, where his father had been minister, and where his literary talents were well known. After fome little time he got an affociation formed for erecting and fupporting a Philanthropine or house of education. A large fund was collected; and he was enabled to travel into Holland and England to engage pupils, and was

furnished with proper recommendations.

In London he gained the friendship of a clergyman, whom he represents as a person in the highest degree accomplished. "With found judgment (fays Balirdt), great genius, and correct tafte, he was perfectly a man of the world. He was my triend, and the only person who warmly interested himself for my institution. To his earnest and repeated recommendations I owe all the pupils that I got in England, and many most respect. able connections; for he was univerfally esteemed as a man of learning and of the most unblemished character. He was my friend, my conductor, and I may fay my preserver; for when I had not bread for two days, he took me to his house, and supplied all my wants."

For so much kindness the reader doubtless supposes that the heart of Bahrdt overflowed with gratitude; but if such be his opinion, he is a stranger to the prin-

Bahrdt. ries, his aim being to form the young mind to the love ciples of those who have on the continent of Europe Bahrdt. affociated for the purpose of enlightening the world. This amiable man, whose character is here so justly drawn, was afterwards depicted by the mouster whom he had faved from perishing by hunger, as a wretch left to all fense of shame and decency, as an apostate from the Christian faith, and as a notorious frequenter of the London brothels! Fortunately he was able to vindicate his character completely from this slanderous abuse, and to convict Bahrdt of having published what could not possibly be true.

This ungrateful liar returned from England, and carried into execution his plan of the Philanthropine. The castle of Count Leining Hartzburgh at Heidesheim, having gardens, park, and every hanfome accommodation, had been fitted up for it; and in 1778 it was confecrated by a solemn religious festival. But his old misfortunes purfued him. He had indeed no colleaques. with whom he could quarrel; but his avorwed publications became every day more obnoxious; and when any of his anonymous pieces had a great run, he could not to far stifle his vanity as to conceal that he was the author. Of these pieces some were shocking to decency, and others fo horribly injurious to the characters of the most respectable men in the state, that he was continually under the correction of the courts of justice. It was hardly possible for a man of letters to be in his company, and not fuffer by it; for it was his constant practice to attribute every flep which he took towards atheilm, to the force of the arguments urged by some of his friends.

To be his friend, or to obtain his applause, was indeed fo great a misfortune, that when the reader fees any person celebrated by Dr Bahrdt, in the beginning of a book, for found fense, profound judgment, accurate reasoning, or praised for acts of friendship to himself, he may be affured, that before the close of the book this man shall be represented as having in private conversation convinced the author, that some doctrine, cherished and venerated by all Christians, is a piece of kna-

vish superstition.

Dr Bahrdt had married, while at Gieffen, a woman with a small fortune: but such a stranger was he to the. delicacies of wedded love, so lost indeed to all sense of decency, that he contrived one day to entice his wife naked into the bath in the garden of his Philanthropine, where, in the water, he, being also naked, toyed with her in the fight of all his pupils. It was his boast that he held his opinions independent of all mankind, and was indifferent whether they procured him praise or reproach: but it appears from this fact, that he was equally regardless of the praise or centure which might be attached to his actions; for furely the groffest hog that ever before him battened in the Epicurean fty would not have presented such an exhibition to boys.

The consequence of all this was, that he was obliged to fly from Heidesheim, leaving his sureties in the Philanthropine to pay about 14,000 dahlers, besides debts without number to his friends. He was imprisoned at-Dienheim; but being toon released, he settled at Halle, where he funk to be the keeper of a tavern and billiardtable. His house became of course the refort and the bane of the students in the university, and he was obliged to leave the city. He had fome how got money sufficient to purchase a little vineyard, pleasantly fituaBahrdt. ted in the neighbourhood. This he fitted up with every accommodation that could invite the students, and called it Bahrat's Ruhe (Bahrdt's repose); where he lived for two years, directing the operations of a fecret fociety called the GERMAN UNION, FOR ROOTING OUT SUPERSTITION AND PREJUDICES, AND FOR ADVAN-CING TRUE CHRISTIANITY.

With Bahrdt's qualifications for advancing the interefts of genuine Christianity, the Christian reader is already fufficiently acquainted; but he will not wonder at his appointment to this high office, when he is informed that the GERMAN UNION is nothing more than a spawn of the sccret society of Illuminati (see ILLU-MINATI in this Supplement); and that its object is to abolish the religion of the gospel, and to teach in its flead the fatalism of the Stoics. With this view Chriflianity is confidered in the UNION as a myflical fociety, and its Divine Founder as the grand mafter of a lodge! The apostles Peter, James, John, and Andrew, were the ELFCT, brethren of the third degree, and initiated into all the mysteries The remaining apostles were only of the fecond degree; and the feventy-two, of the first: a degree into which ordinary Christians may be admitted, and prepared for farther advancement. The great my-Itery is, that I - C - was a NATURALIST, and taught the doctrine of a supreme mind, the spectator but not the governor of the world.

To propagate these impious and absurd notions, Bahrdt published many books of the most antichristian tendency, and fome of them calculated to make their readers shake off all moral obligation. But the labours of the fociety were not confined to religion; it inculcated on its members the most dangerous maxims of civil conduct: for, as we learn from Bahrdt himself, the objects at which the Union aimed were - Advancement of science-a general interest and concern for arts and learning-excitement of talents-chesk of scribbling-good education - LIBERTY - FQUALITY - hospitality - DELIVERY OF MANY FROM MISFORTUNES—union of the learned and at last - perhaps - Amen.

What the meaning of this enigmatical conclusion is we can only guess; and we agree with the real philoso. pher from whom we have taken this account, that our conjectures cannot be favourable Bahrdt was a villain, and could be affociated only with villains, whose affairs he managed with the help of an old man, who lived at bed and board in his house for about fix shillings a week, and discharged the office of secretary to the Union.

When he had toiled in this cause near two years, some of the secrets of the Union transpired; his former conduct and his constant imprudence made him suspected; his affociated friends lodged informations against him; his papers were feized; and he himfelf was fent to prison, first at Halle and then at Magdeburg. After fomething more than a year's confinement, he was fet at liberty, and returned to his Ruhe, not, alas! to live at ease, or to exhibit symptoms of repentance, but to lie down on a fick-bed, where, after many months fuftering of increasing pain, he died on the 23d of April 1792, the most wretched and loathsome victim of unbridled fenfuality.

Such were the fruits of the German Union, and of that illumination which was to refine the heart of man, and bring to materity the feeds of native virtue, which are choaked in the heart by superstition and despotism.

Dr Bahrdt affected to be the enlightener and reformer Bahrdt; of the world; and affirmed, that all the evils of life originated from despotism and superstition. " In vain (lays he) do we complain of the inefficacy of religion. All positive religion is founded on injustice. No prince has a right to prescribe or sanction any such system; nor would he do it, were not the priests the sirmest pillars of his tyranny, and superstition the strongest fetters. for his fubjects. He dares not show Religion as she is, pure and undefiled- she would charm the eyes and the hearts of mankind, would immediately produce true morality, would open the eyes of freeborn man, would teach him what are his rights and who are his oppreffors, and princes would vanish from the face of the earth."

Therefore, without troubling ourselves with the truth or falsehood of his religion of nature, and assuming it as an indisputable point, that Dr Bahrdt has seen it in this natural and so effective purity, it is surely a very pertinent question. " Whether has the fight produced on his mind an effect fo far superior to the acknowledged faintness of the impression of Christianity on the bulk of mankind, that it will be prudent to adopt the plan of the German Union, and at once put an end to the divisions which fo unfortunately alienate the minds of professing Christians from each other?" The account here given of Dr Bahrdt's life feems to decide the question.

But it will be faid that we have only related to many instances of the quarrels of priests and their slavish adherents with Dr Bahrdt. Let us view him in his ordinary conduct, not as the champion and martyr of illumination, but as an ordinary citizen, a husband, a father, a friend, a teacher of youth, a clergyman.

When Dr Bahrdt was a parish-minister, and president of some inferior ecclesialtical district, he was empowered to take off the censures of the church from a young woman who had born a bastard child. By violence he again reduced her to the same condition, and escaped censure by the poor girl's dying of a sever before her pregnancy was far advanced, or even legally documented. On the night of the folemn farce of confecrating his Philanthropine, he debauched the maid-fervant, who bore twins, and gave him up for the father. The thing was not judicially proved, but was afterwards made fufficiently evident by letters found among his papers, and published by one of his friends in the UNION. Having supported these infants, in a pitiful manner, for little more than a year, he caused them to be taken. away from their mother, during night, fome time in the month of February 1780; and they were found. exposed, the one at Ufstein, and the other at Worms, many miles diffant from each other, and almost frozen

So much for the purity of his morals and his religion, as he appears in the character of a father and of a clergyman. His decency as a husband, and his gratitude to his friend, we have already feen; and we shall now see his kindness and sidelity. wasting the greatest part of his wife's little fortune, he was fo provoked because her brother would not give him up the remainder, amounting to about L. 110, that he ever afterwards treated her with the greatest cruelty, and exhibited her to contempt and ridicule intwo infamous novers. At Halle he brought a mistress into the house, and committed to her the care of his family, confining his wife and daughter to their own apartment.;

Bahrdt, apartment; and the last thing which he did was to Bailly. fend for a bookfeller, who had published some of his vilest pieces, and, without a thought of his injured wife, recommend his strumpet and her children to his protec-

> "Think not, indignant reader (fays Arbuthnot), that this man's life is useless to mortals." It shows in a strong light the falfity of all his declamations in favour of his fo much praised natural religion and universal kindness and humanity. No man of the party writes with more perfualive energy, and, though his petulance and precipitant felf-conccit lead him frequently altray, no man has occasionally put all the arguments of these philosophers in a clearer light; yet we see that all is false and hollow. He is a vilc hypocrite, and the real aim of all his writings is to make money, by foftering the fenfual propenfities of human nature, although he fces and feels that the completion of the plan of the German Union would be an event more destructive and lamentable than any that can be pointed out in the annals of superstition. We will not say that all the partisans of illumination are hogs of the fty of Epicurus like this wretch; and it would be extremely unjust to confider his vices as the effects of his illumination. He was fenfual, ungrateful, and profane, before he was admitted into the order of the Illuminati; but had the views of that order been such as were held out to the world at large, its fagacious founder would not have initiated a wretch fo notoriously profligate as Dr Bahrdt. Their views, however, being to govern mankind thro' the medium of their fenfual appetites, and to reign in hell, rather than ferve in heaven, they could not have employed a better instrument. Dr Bahrdt was a true disciple of illumination; and though his torch was made of the coarfest materials, and served only to discover fights of woe, the horrid glare darted into every corner, roufing hundreds of filthy vermin, and directing their flight to the rotten carrion, where they could best deposit their poison and their eggs. Whilst the more decent members of the Union laboured to pervert the refined part of mankind by declamations on the rights of man and the bleffings of liberty, Bahrdt addressed himfelf to readers of all descriptions, and affailed at once the imagination and the appetites. He taught them, that religion is an imposture; that morality is convenience; and, with blafphemy peculiar to himfelf, that he and his order, by their licentious doctrines, were to complete the plan and aim of J -- C-

> BAILLY (Jean-Sylvian), who made fuch a figure during the first years of the French revolution, was born at Paris on the 15th of September 1736, of a family which had been diftinguished painters during four fuccessive generations. He was bred to the same profesfion, but showed an early taste for poetry and the belles lettres. Chancing, however, to become acquainted with the geometer La Caille, this circumstance decided his genius, and he thenceforth devoted himself to the cultivation of science. He calculated the orbit of the comet of 1759; and on the 20th of January 1763 was received into the Academy of Sciences. In that year he published an useful and laborious compilation, being the reduction of the observations made by La Caille in 1760 and 1761, on the zodiacal flars. He likewise began to confider the theory of Jupiter's fatellites, and, in the competition for this prize question of 1764, had a

formidable rival in La Grange, who already promifed to Bailly. become the first mathematician in Europe. The refults of his investigations were collected into a treatife published in 1766, containing also the history of that part of astronomy. In 1771 he gave a most curious and important memoir on the light of the fatellites, and introduced a degree of accuracy till then unknown in the observations of their eclipses.

His studies were not confined to the abstract sciences; for he cultivated letters with success. His eloges of Charles V. of Corneille, of Leibnitz, of Moliere, and afterward those of Cook, La Caille, and Gresset, were much admired. His eloquence pointed him out as a proper person to fill the charge, vacant in 1771, of secretary to the Academy of Sciences; and, under the patronage of Buffon, he flood candidate for that cuviable place. He failed: but it was the high birth and promiting talents of the young Condorcet, joined to the active influence of D'Alembert, that carried the prize.

In 1775 appeared the first volume of the History of Aftronomy, which indeed ftrews the path of science with flowers, and in every respect is a most valuable work-full of animated description, of luminous narrative, and interesting detail. His very peculiar ideas concerning the early state of Upper Asia gave rise to an ingenious correspondence and discussion with the veteran philosopher Voltaire, the substance of which soon appeared in two volumes, intitled, " Letters on the Origin of Sciences," and "Letters on the Atlantide of Plato." If imagination shone forth in these essays, erudition was no less conspicuous in a great work compofed in the years 1781 and 1782, on the fables and religiors creeds of antiquity; which still exists in manufcript, and the publication of which would affuredly extend the fame of its author and gratify the learned world. His opinions on some points happening to coincide with the theories of Buffon, he contracted with that celebrated naturalist a close friendship, which was diffolved by Bailly's uncourtly opposition to the election of the Abbé Maury into the Academie Française. Of that academy he had been chosen fecretary in 1784; and he was admitted, in the following year, into the Academy of Inscriptions and Belles Lettres; the only instance, fince Fontenelle, of the same person being at once a member of all the three academies. In the meantime, the other volumes of the History of Astronomy fuccessively appeared, and that capital work was completed in 1787 by the History of the Indian and Oriental Astronomy; a production of singular acuteness, refearch, and nice calculation.

In 1784 he made an elegant report to the Academy of Sciences on the animal magnetism of Mesmer; and in 1786 another report, which displays the judgment and humanity of its author, on a project for a new botel-dieu or infirmary.

We now approach the eventful period which fummoned Bailly from his retirement, to enter on a political career, that was full of difficulty and danger, and for which his habits and itudies appear not to have fitted him. He had feen, as others faw, the defects of the old government of France. His heart panted for civil and ecclefiaftical liberty; but unfortunately, like many other philosophers both in his own country and in this, he had formed notions of that bleffing which experience should have taught him can never be realised among be-

ings so imperfect as the bulk of mankind. When the ftates general were fummoned to meet, he was on the 26th of April 1789 nominated fecretary by the electors of Paris, and then appointed one of the deputies. He was chosen prefident of the Tiers Etat; and when that chamber was constituted the National Assembly, he continued in the chair, and concurred in all the levelling decrees which laid the foundation of the prefent misery of his country, as well of most other countries of

After the taking of the Bastile, when the king was removed to Paris on the 15th of July, Bailly was called by public acclamation to the head of that city, with the title of Mayor. In his feveral functions he acted with integrity, courage, and moderation. He reached the fummit of glory :- but how mutable, alas! is human grandeur! That middle course of conduct, the aurea mediocritas, at which virtue aims, is fitted to please neither of the contending parties in the midst of revolutions; and fuch proved the ruin of Bailly. His popularity began to decline, and was at length changed into inveterate enmity by an unfortunate accident. On the 17th of July 1791, the populace having collected tumultuously to demand the abolition of monarchy, Bailly was ordered by the National Affembly to difperse the mob. He was obliged to proceed to the Champ-de-Mars at the risk of his life; and, in spite of all his exertions and forbearance, fome shots were fired by the foldiery. It was no longer defirable to hold his perilous charge, and on the 16th of November following he gave way to the afcending reputation of Petion. The impaired state of his health, too, rendered it expedient to retire from the focus of turbulence. He spent the year 1792 and part of 1793 in travelling through different provinces of France. During this period he wrote memoirs of the events which he had witneffed, and in which he had often been a principal actor. These come down only to the 2d of October 1789, but would make a large quarto volume; and La Lande, from whose Eloge de Bailly this article is taken, gives us hopes that the manufcript will be published. He was advifed by his friends to withdraw from France, but he chose rather, like Socrates, to submit to the injustice and ingratitude of his country. At the nod of a vulgar tyrant he was arrested, summarily condemned by a fanguinary tribunal, and on the 15th of November. 1793 was delivered over to appeale the vengeance of an incenfed and indifcriminate populace. His fufferings were studiously protracted, but he bore them with the calmness and magnanimity of a sage. Nature recoils at the recital of fuch barbarities.

In 1787 M. Bailly married the widow of one who had been during 25 years his intimate friend; a woman more qualified by her age and condition to inspire respect than the passion of love. He was tall in his perfon, of a ferious deportment, and joined firmness to fenfibility. Never did philosopher distinguish himself in to many different lines, nor acquire fuch deferved reputation in them all. His difinterestedness was pure and unaffected; and during his magistracy he spent a part of his fortune in relieving the wants of the poor. His virtue remained as untainted in his various public stations as in the fweet retirement of domestic life.

Such is the encomium passed upon this philosopher and statesman by no less a man than the celebrated astronomer M. DE LA LANDE; but to those who are not infected with the mania of freedom, it will doubtless appear greatly exaggerated. That M Bailly was a man of eminence in the republic of letters, is known to all the learned of Europe; that in his political conduct he meant to promote the good of his country, it would certainly be presumptuous in us to deny; and that he suffered unjuffly, is incontrovertible: But let it be remembered, that he fuffered in a florm, which he exerted all his abilities to raise; and that he set an example of injustice, when he concurred in the degradation of the privileged orders, and in the violent confication of the property of the church.

BALIOL (John), the competitor with Bruce for the crown of Scotland, was not (as he is faid to have been in the Encyclopadia) the brother of King ALEX-ANDER, but the great grandson of David Earl of Hun-

tington, third fon of King DAVID I.

BALLISTIC PENDULUM, an ingenious machine invented by Benjamin Robins, for afcertaining the velocity of military projectiles, and confequently the force of fired gunpowder. It confifts of a large block of wood, annexed to the end of a strong iron stem, having a cross steel axis at the other end, placed horizontally. about which the whole vibrates together like the pendulum of a clock. The machine being at rest, a piece Hutton's of ordnance is pointed straight towards the wooden Dictionary block or ball of this pendulum, and then discharged: the confequence is this; the ball discharged from the gun strikes and enters the block, and causes the pendulum to vibrate more or lefs according to the velocity of the projectile or the force of the blow; and by observing the extent of the vibration, the force of that blow becomes known, or the greatest velocity with which the block is moved out of its place, and confequently the velocity of the projectile itself which struck the blow and urged the pendulum.

BANKA (see Banca, Encycl.) is noted throughout Afia for its tin mines. It lies opposite to the river Palambang, in the island of Sumatra, on which the fovereign of Banka, possessor also of the territory of Palambang, keeps his constant residence. This prince maintains his authority over his own fubjects, and his independence of the neighbouring fovereigns, chiefly by the affiftance of the Dutch, who have a fettlement and troops at Palambang, and enjoy the benefit of a contract with the king of Banka for the tin which his subjects procure from that island. Such at least was the case in 1793, when Lord Macartney touched at Banka on his way to China. At that period the fovereign compelled his subjects, and probably does fo at present, to deliver the tin to him at a low price, and fold it to the Dutch at a small advance, purfuant to his contract. Those miners, from long practice, have arrived at great perfection in reducing the ore into metal, employing wood as fuel in their furnaces, and not fossile coal, or coak, which is feldom so free from fulphur as not to affect the malleability of the metal. It is sometimes preferred therefore to European tin at the Canton market; and the profit upon it to the Dutch company was, at the period mentioned above, fupposed to have long been not less than I. 150,000 ayear. Into whole hands this trade has now fallen we know not; probably it is in a great degree neglected.

BANTAM, the capital of a kingdom of the same name in the island of Java, is, in the Encyclopadia, said

Bantam fince that article was published, gives a very different account both of the town and of its harbour. Once indeed it was a place of confiderable confequence, being the great mart for pepper and other spices, whence they were distributed to the rest of the world. The chief factory of the English as well as Dutch East India Company was fettled there. The merchants of Arabia and Hindostan resorted to it. Its sovereigns were fo defirous of encouraging trade, by giving fecurity to foreign merchants against the violent and revengeful disposition of the natives, that the crime of murder was never pardoned when committed against a stranger, but might be commuted by a foreigner for a fine to the relations of the deceased. This place flourished for a considerable time; but the Dutch having conquered the neighbouring province of Jacatra, where they fince have built Batavia, and transferred their principal bufiness to it, and the English baving removed to Hindostan and China, and trade in other respects having taken a new courfe, Bantam was reduced to a poor remnant of its former opulence and importance. Other circumstances have accelerated its decline. The bay is fo choked up with daily accessions of new earth washed down from the mountains, as well as by coral shoals extending a confiderable way to the eastward, that it is inacceffible at present to vessels of burden; even the party who went there from the Lion, the ship which carried Lord Macartney to China, was obliged to remove from her pinnace into a canoe, in order to reach the town. With the trade of Bantam the power of its fovereign declined. In his wars with other princes of Java he called in the affiftance of the Dutch; and from that period he became in fact their captive. He resides in a palace, built in the European style, with a fort garrisoned by a detachment from Batavia, of which the commander takes his orders not from the king of Bantam, but from a Dutch chief or governor, who lives in another fort adjoining the town, and nearer to the feafide. His Bantamete majesty is allowed, however, to maintain a body of native troops, and has feveral small armed veffels, by means of which he maintains authority over some parts of the south of Sumatra. His subjects are obliged to sell to him all the pepper they raise in either island, at a low price, which he is under contract with the Dutch to deliver to them at a small advance, and much under the marketable value of that commo-The present king joins the spiritual to the temporal power, and is high priest of the religion of Mahomet; with which he mingles, indeed, fome of the rites and superstitions of the aboriginal inhabitants of Java; adoring, for instance, the great banyan, or Indian figtree, which is likewise held sacred in Hindostan, and under which religious rites might be conveniently performed; in like manner, as all affairs of state are actually transacted by the Bantamese under some shadowing tree by moonlight. To complete the ruin of Bantam, a fire some time ago destroyed most of the houses, and few have been fince rebuilt.

BANYAN-TREE. See Ficus, Encycl.

BRITISH BARILLA, is the name given by Mr Tames King of Newcastle upon Tyne, to a material invented by him to supply the place of Spanish barilla in the making of crown window-glass, broad window-glass,

Bantam to be a large town with a good harbour and fortified and glass bottles, as also in the manufacturing of soap Bartlla, castle. Sir George Staunton, however, who visited and alum. For these purposes he affirmed that it an Barthelem fwered much better than any other material then in use; and in consequence of that affirmation he obtained a patent for his invention, dated March 4. 1780.

Though we can hardly allow to this invention all the merit claimed for it by its fond author, yet as it may be of use to different manufacturers, we shall lay before our readers his method of making the British barilla. It is as follows: "Take a certain quantity of ashes obtained by burning the loopings or branches of ash, oak, beech, elm, alder, or any other kind of green wood or bramble: Take an equal quantity of the ashes obtained by burning the green vegetables known by the name of fern, brecon, bean and pea-straw, whins, common field and high-way thiftles, the stalks of rape or multardfeed, or the bent or rushes that grow by the sea shore." Though we know not in what qualities the ashes obtained from the former substances differ from those obtained from the latter, the author, as if the difference was very great, directs these equal quantities to be mixed together, fifted through a fine fieve, and laid upon a boarded floor, where a quantity of foapers waste-ashes, equal to the whole compound mats, is to be added to it, and well mixed with it by means of a shovel or other instrument. To this mixture of vegetable ashes and foapers wafte-ashes is to be added a quantity of fine quick-lime, in the proportion of one hundred weight to twelve hundred of the blended askes, and the lime and ashes are to be well mixed together. After this the whole is to be put into an iron pan, into which is to be poured a quantity of fea-water fufficient, fays the author, to disfolve the ashes and lime; and the whole is to be flirred with an iron rake till it incorporate. This being done, a coal fire is to be lighted up under the pan, and kept burning for two days and two nights without intermission, additional quantities of sea-water being confrantly supplied to impregnate the materials with saline matter fufficient for calcination in a reverberating furnace or calcar. In this calcar the faline mass, which was boiled in the pan, is by intense heat to be dissolved, and kept in a state of fusion for the space of an hour; during which time the volatile part flies off, and leaves remaining a fixed alkaline falt, which, cooled in iron pans, is the British barilla, and has the appearance of Spanish barilla. See BARILLA, Encycl.

BARTHELEMI (Jean Jacques), the Nestor of French literature, was a man so eminent for his knowledge of antiquities, that every classical reader must be interested in his fate. He was born, we believe, at Paris about the latter end of the year 1715; and being educated for the service of the church, he became prior of Courcay, keeper of the medals and antiques in the French king's cabinet, and in 1747 was elected a member of the Academy of Inscriptions. From that period his life was wholly devoted to letters; and in recording the principal events of it, we can only enumerate, in

their order, his various publications.

A differtation of his on the river Pactolus was read 1748 (Hist. de l'Acad. X. 29.); Reflections on a Medal of Xerxes, King of Arfamata (Mem. de l'Acad. XXXVII. 171.), found, or faid to be found, by Fourmont in the temple of Apollo Anycleus (XXXIX. 129.); Effay on Numismatic Palæography, ib. 223; Differtation on two Samaritan Medals of Antigonus

King

King of Judea, ib. 257; Remarks on some Inscriptions published by different anthors, XLV. 99; Differtation on Arabic Coins, ib. 143; by which it appears that the Mohammedan princes copied the heads of Greek and Roman ones on their coins, and gave Arabic inscriptions of their own names on the reverse. On the Ancient Alphabet and Language of Palmyra, ib. 179; on the Ancient Monuments of Rome, the result of a tour in Italy to collect medals for the royal cabinet, to which he added 300, XLIX. 151; on some Phænician Mo. numents, and the Alphabets formed from them, LIII. 23. The characters on the written mountains, which he here cites, have been proved of no value; and he ilinstrates the conformity between the Phonician and the Egyptian characters from the latter on the bandages of the mummies. Explanation of the Mofaic Pavement of the Temple of Præneste, ib. 149; of which there have been four engravings fince its first discovery in 1650, and which Barthelemi refers to the voyage of Adrian into Egypt. It may be of that date, but there is no reason to suppose that it represents any thing more than an Egyptian landscape. The form of letters determines the date in the judgment of the learned Abbé. On the Relations of the Egyptian, Phonician, and Greek Languages, LVII. 383; on some Medals published by different authors, LIX. 270; Explanation of an Inscription under a Bas-relief in the Bishop of Carpen. tras's Library, 1767, ib. 365; on the Number of Pieces represented in one Day on the Theatre at Athens, LXXII. 286; three Comedies, as many Tragedies, a Satire, and a Petite Piece; Remarks on some Medals of the Emperor Antoninus flruck in Egypt, LXXX. 484. 1775 (A).

His interpretation of the Phonician infeription at Malta, LIII. 23, was controverted by our learned linguist, Mr Swinton, in Philos. Transact. LIV. art. xxii. p. 119; in farther remarks, ib. art. lxx. p. 393.

In 1792 he published a differtation on an ancient Greek inteription, containing an account of expences of the public feats under the archontate of Glaucippus,

410 years before Christ.

The intimate acquaintance which he had cultivated with classical antiquity, enabled him, in the close of a long life, to compose that chef-d'œuvre, the "Travels of the Younger Anacharsis into Greece" in the middle of the fourth century before the vulgar era. In representing the curiofity of a Scythian savage (for we cannot confider in any other light the man who put mufic and the excesses of the table on the same level), he takes occasion to interweave very curious and instructive details on the laws, religion, manners, customs, and general spirit, of a great nation, as well as its progress in arts and sciences. The epoch which he has chosen is that of letters and arts, combining the age of Pericles with that of Alexander, the revolution which changed the appearance of Greece, and foon after overturned the empire of Persia. The introduction comprehends the 1250 years elapsed from the age of Cecrops to the supposed era of Anacharss, in two intervals; the first reaching to the commencement of the Olympiads, the fecond to the capture of Athens by the Lacedemonians. The SUPPL. VOL. I. Part I.

history of the Athenians commences about 150 years Bartheafter the first Olympiad, including the age of Solon, or that of legislation; that of Themiltocles and Aristides, or that of glory, of luxury, and arts. In the fecond, speaking of war, his observation, that "the example of one nation, that prefers death to flavery, is too important and too indructive to be passed in filence," should have preferved him from the horrors of a long confinement in an advanced age, from which he was delivered only to die. But arts, sciences, and literature, are alike forgotten and overwhelmed in France. In the third interval, speaking of the corruption of manners introduced by Pericles to Support his power, he has this obfervation, applicable to every flate: " Corrupted morals are not reflored but by the less of liberty, which brings that poverty inconsistent with softness, and inseparable from abstemiousness, if not that rigid principle of a healthy mind, which is properly called virtue." In this period, though the arts were encouraged, philosophy was neglected.

In this diversified undertaking, where the picture of ancient Greece in its minutest parts, both of public and private use, is brought before our eyes, the Abbé is frequently more brilliant than solid, and occasionally loses the substance of a respection in pursuit of something ingenious to add to it. The plans, views, and maps, are executed with great spirit and accuracy by Mr Barber, a young man of very promising talents; and to the charts many useful tables are added. The beauties of the classics are diffused in a very pleasing manner, and

interspersed with anecdotes little known.

Such was the man whom the French government detained in prison for months, and released on the fall of Robespierre. As he concurred in the revolution, we know of no cause for his imprisonment but the mildness of his disposition, and the jealousy of that tyrant, which pursued, with relentless cruelty, every man suspected of being a friend to peace. Of the perfecution of Bartheleni, in the extremity of old age, the convention itself seemed to be ashamed; for it unanimonsly voted him a pension as some recompence for his sufferings. But, alas! the recompence came too late: the old man lived but a sew months after his liberation, having died at Paris on the 4th of May 1795; and the day after the solowing tribute was paid to his memory by Dussalk, in the national convention:

"Legislators, your liberality conferred honour on the latter days of the life of our respectable sellow citizen, Darthelemi. Our successors, I have no doubt, will confecrate his memory so soon as the period fixed by the law shall permit them. May his old friend, however, be permitted, in a few words, to point out the rare qualities of that Nestor of French literature? It might, perhaps, be sufficient to tell you, as Xenophon said with so much simplicity of one of his most illustrious contemporaries, that Barthelemi was an excellent man in all respects. In fact, those who knew him were at a loss which to admire most—his immortal Anachassis, or his own life. His policy consisted in goodness; his science was an immense treasure of every thing that could purify the morals, perfect the taste, render man

Barthelemi more dear to man, and contribute to the splendour of his country. A fingle trait will convince you of the mildness of his philauthropic mind: 'Why is it not permitted (he often faid) to a mortal to bequeath profperity to his fellow-creatures?' After having been overwhelmed with the favours of fortune, which came unexpectedly and unfought, he became poor; yet his character, far from finking under the pressure, acquired new respect; and he proved that poverty, supported with dignity, is not less honourable than wealth accompanied with benevolence. Perfecuted, as all virtuous and enlightened citizens were, he carried with him to the dungeon of that tyranny which you have so gloriously destroyed, the constancy and serenity of Socrates. It was there that the venerable old man offered to his companions in misfortune the magnificent spectacle of a good man struggling with adversity. I have faid that he was rich; but let us not forget that he was not rich at the expence of the unfortunate, and that he adopted all the branches of his numerous family. The republic has gained by that family good citizens, who ferve her in the most useful and brilliant manner. Barthelemi felt that the period of his diffolution was approaching; yet though exhaufted by long fatigue, and bending beneath the weight of 80 years, his fenfibility was still vigorous, and your just decrees made the closing scene of his life happy. When he heard that you were endeavouring to repair the ills under which fo many thousand innocent men laboured, he lifted up his hands to heaven, and exclaimed, 'Glory to God-honour to the national convention-I have lived long enough!' In the prefent posture of affairs, the country demands all your attention. I shall therefore confine myself to request the favour due to the manes of the illustrious Barthelemi. One of his nephews, I do not mean your respectable ambassador at Basse, but the citizen Courcey, has, for 25 years, discharged all the duties of a son to his uncle, and for a long time has performed the functions of keeper of the medals and antiquities of the national cabinet. I move, that the citizen Courcey be appointed to that office, which he has already proved himself fo worthy to fill."

Whatever became of this motion, which was referred to the committee of public instruction, the cruelty of the government purfued the family; and the late banishment of his other nephew by the directory, of which he was a member, furpasses, if possible, the injustice of Robespierre to the uncle. But their crimes were the fame: both Barthelimis were men of mild dispositions

and friends to peace.

BARYTES, one of the earths. See CHEMISTRY

in this Supplement, Part I. Chap. iv.

BASTER, the name given by the Dutch at the Cape of Good Hope to the offspring of a white man

and Hottentot woman.

BAT, an animal which has been described under its generic name VESPERTILLIO in the Encycl. but fince that article was written, we have met with an account of a new species, so very fingular, that, if the veracity of our author can be depended on, it is well intitled to a place here. This species was discovered in the country of the Nimiquas, in the interior of Africa, by M. Vaillant, during the course of his second travels, and is by him called the orcillar bat. To this title it has indeed a very good claim; for it has, he fays, four

ears, or at least the external part of four ears, each Batavia. ear being double; the outer fold, which ferves as a covering to the inner, is very ample, being two inches eight lines high, and nearly as broad when stretched out. On the nose also a membrane stands erect, one inch four lines in height, which might be taken for another ear, as it has exactly the shape of one. This membrane, as well as the ears and wings of the animal, are of a rufty red, paler below than above. The body is only three inches long, and is covered with very fine greyish hair. Its width, from the tip of one wing to that of the other, is eight inches. The reader will pardon me, fays our author, for inferting these trifling details of measurement, of which I am not more fond than himself; but they appeared to me necessary here, to convey an accurate idea of the extraordinary length of the ears of this animal, which are certainly larger in proportion than those of any other we are acquainted with, fince they are only four lines, or the third part of an inch, fhorter than the body itself.

BATAVIA, the capital of the Dutch fettlements in the East Indies, has been already described under the article JAVA in the Encyclopædia. The following account of it, however, 2s well as of the country around it, and the manners and customs of its various inhabitants, as they presented themselves to Sir George Staunton in March 1793, will probably prove acceptable to

many of our readers.

The city of Batavia, including the suburbs, consists of near eight thousand houses, inhabited by Dutch, Chincse, and natives of Java. The houses of the Chinese are low, and crammed with people. The Dutch houses are well built, clean, and spacious, and their construction for the most part well fuited to the climate. The doors and windows are wide and lefty. The ground floors are covered with flags of marble, which being sprinkled frequently with water, give a pleasant coolness to the apartment; but a considerable proportion of those was untenanted, which denoted a declining fettlement. Among other circumstances which announced the same, were those of the Company's vessels lying useless in the road, for want of cargoes to fill, or men to navigate them; no ships of war to protect their commerce, even against pirates, who attacked their vessels fometimes in the fight of Batavia road; an invafion threatened from the Isle of France; the place in no condition of defence, particularly against an enemy less affected by the climate than Europeans; fometimes as many of the troops in hospitals as fit for duty; commissioners expected from Holland to reform abuses. Such a commission, implying a general suspicion, could not be welcome; nor was it quite certain whether, in fome minds, its arrival or that of the enemy was deprecated the most cordially.

The fortifications of Batavia, though a place of for much importance, were not, when Sir George faw them, fuch as would be deemed formidable in Europe; but when the difficulties were confidered of forcing the paffage of the river, or of landing troops on other parts of the island, it might perhaps be thought of greater strength than it would at the first view have credit for. The defences of the river were the water fort, fituated at its entrance, liaving mounted or difmounted fourteen guns and two howitzers. fifted of a parapet, originally well constructed, retained

The castle is built of coral rock, brought from some Batavia. of the adjoining islands, composed of that material; and has the advantage of a fortification of brick, in which cannon ball is apt to bury itself without spreading splinters or shattering the wall. A part of the town wall is built of lava, which is of a dark blue colour, of a very hard dense texture, emits a metallic found, and resembles very much fome of the lava of Vesuvius. It is brought from the mountains in the centre of Java, where a crater is still smoking. No stone of any kind is to be found for many miles behind the city of Batavia. Marble and granite are brought thither from China, in veffels belonging to that country, commonly called junks, which generally fail for Batavia from the ports of the provinces of Canton and Fokien, on the fouthern and fouth east coasts of that empire, laden chiefly with tea,

porcelain, and filks.

The chief protection of Batavia against the attacks of a foreign enemy, arises from the havoc which it is well known the climate would make amongst European troops. This was acknowledged to Lord Macartney by some of the Dutch officers themselves and even by one of the counsellors of the Indies. Such indeed is the climate, that there have been very few examples of strangers remaining long in Batavia without being attacked by fever, which is the general denomination in that place for illness of every kind. Europeans foon after their arrival first become languid and feeble, and in a few weeks, or even in a few days, are taken feriously ill. The disorder at first is commonly a tertian ague, which after two or three paroxysms becomes a double tertian, and then a continued remittent, that frequently carries off the patient in a fhort time. Many fall victims to the fecond or third fit; but in these cases a conftant delirium, and a great determination of the blood to the brain, accompany the other fymptoms. In fome it begins in a quotidian form, with regular intermissions for a day or two; and then becomes a continued remittent, attended with the fame fatal confequences as the former. Of the Europeans of all classes who come to fettle at Batavia, it is supposed that not half the number always survives the year. The place resembles in that respect a field of battle or a town besieged. The frequency of deaths renders familiar the mention of them, and little figns are shewn of emotion or lurprise on hearing that the companion of yesterday is to-day no more. It is probable, female Europeans tuffer less at Batavia than the men. The former feldom expole themselves to the heat of the fun, make frequent use of the cold bath, and live more temperately than the other fex.

But it is not to those who have lately arrived from Europe that this havoc is wholly confined. The greatest number of the Dutch settlers, even those who had refided long in the country, appeared wan, weak, and languid, as if labouring with the "difease of death." Their place of refidence, indeed, is fituated in the midst of fwamps and stagnated pools, from whence they are every morning faluted with " a congregation of foul and peftilential vapours," whenever the fea breeze fets in, and blows over this morafs. The meridian fun raites from the shallow and muddy canals, with which the town is interfected, deleterious miasinata into the air; and the trees, with which the quays and ftreets are crowded, emit noxious exhalations in the night.

The general reputation of the unhealthiness of Bata-

latavia. by a wall; but the parapet was much neglected, and the wall nearly deftroyed by the conftant working of the sea. This fort was protected on the land side by a noxious fwamp, and towards the fea, on the northwest, by extensive flats, over which even boats could not pals. The only good approach was that by the channel, which it fees and defends. The next work upon the river was on the west shore, about a quarter of a mile from the water fort. It is a battery mounting feven guns, bearing down the river. Opposite to this was a battery of fix guns, facing the river, and two to the eastward. This formed one flank of a line that occupied the low land to the north-east of the town. The line was a low breast-work of earth, that was fcarcely discoverable. The canals which intersect the town joined the great canal or river, at the distance of half a mile from the entrance. Below the junction a boom was laid of wood, armed with iron spikes. A little above was the castle, a regular square fort, but without ravelins or other outworks. It had two guns mounted on each flank, and two, or fometimes three, on each face: they were not en barbette, nor properly en embrasure, but in a situation between both, having both their disadvantages without the advantage of either. The wall was of masonry, about 24 feet high. It had no ditch, but a canal furrounded it at some distance. It had no cordon. The length of the exterior fide of the work was about 700 feet. The town is rectangular, three quarters of a mile long, and half a mile broad, inclosed by a wall of about 20 feet in height. Small projections were constructed, of various forms, at intervals of about 350 feet. These generally mounted three guns each. It was also surrounded by a canal, having several sluices. At short distances from the town, three or four small flar forts of earth were erected in particular passes, perhaps for defence against the inhabitants of the island.

> The establishment of regular troops was 1200 Europeans, of whom 300 were to be artillery, the rest infantry. But as it was found impossible, on account of the climate, to keep the number complete, recourse was had to the natives, of whom 500 were employed; so that the establishment of European regulars was reduced to 700. There were also 300 volunteers of the town, who were formed into two companies, but they were not disciplined. Their regulars were very numerous, confifting of enrolled natives of Java, who were never embodied, and of Chinese, of whom the Dutch were so jea lous as to arm them with lances only. Much dependence was not to be placed on the exertions of either of these bodies in favour of the Dutch; and as they lose many of their European troops every year, their establishment appeared too small for any effectual refistance. The chief protection of their ill manned veffels lying here, must be from the fortified island of Onruft, well fituated to command the channel that affords the principal paffage into the road. The work upon that island was of a pentagonal form; its bastions were small and low, not more than 12 feet the highest, and not always connected by curtains. A few batteries were lately constructed on the outside of this work, that bore towards the sea. On these and on the bastions about 40 guns were mounted in different directions. South of these was another island, at the distance of a few hundred yards, on which two batteries, mounting together 12 guns, had been lately erected.

notwithstanding the temptations of fortunes to be quick. ly amassed in it. From this circumstance it happens, that offices and professions are often necessarily entrusted to persons little qualified to fill them. One of the clergymen, and the principal physician of the place, were both faid to have originally been barbers. The United Provinces furnish even few military recruits. The rest are chiesty Germans, many of whom are said to have been kidnapped into the fervice. Though nominally permitted, after a certain length of time, to return home, they are in fact compelled to enlift for a longer time, the pay being too feanty to allow them to lave enough to defray the expence of their passage to Europe. The government is accused of the barbarous policy of intercepting all correspondence between those people and their mother country; by which means they are deprived of the consolation of hearing from their friends, as well as of the chance of receiving fuch affistance as might enable them to get home.

Difficult, however, as it is, on account of the climate, to recruit the army, fuch is the defire of accumulating wealth in a foreign land, that it draws annually great numbers of Chinele as well as of Dutch to Batavia. Both indeed belong generally to the humbler claffes of life, and are bred in fimilar habits of industry in their own country; but the different circumstances that attend them after their arrival in Batavia put an end to any further refemblance between them. The Chinese have there no way of getting forward but by the continuance of their former exertions in a place where they are more liberally rewarded, and by a ftrict economy in the preservation of their gains. They have no chance of advancing by favour, nor are public offices open to their ambition; but they apply to every industrious occupation, and obtain whatever either care or labour can accomplish. They become in town retailers, clerks, and agents; in the country they are farmers, and are the principal cultivators of the fugar-cane. They do at length acquire fortunes, which they value by the time and labour required to earn them. So gradual an acquisition makes no change in their disposition or mode of life. Their industry is not diminished, nor their health impaired. The Dutch, on the contrary, who are fent out by the Company to administer their affairs in Asia, become soon fensible that they have the power, wealth, and possessions of the country at their disposal. They who furvive mount quickly into offices that are lucrative, and not to them laborious. They rife to the dignity of governor-general and counsellors of the Indics, as the members of the Batavian government are called. Their influence likewise enables them to speculate in trade with vast advantage. The drudgery and detail of bufinefs are readily undertaken by the Chinese; while their principals find it difficult, under such new circumstances, to retain their former habits, or to refift a propenfity to indolence and voluptuonfnefs, though often attended with the facrifice of health, if not of life. Convivial pleafures, among others, are frequently carried to excefs.

In several houses of note throughout the settlement, the table is spread in the morning at an early hour: belide tea, coffee, and chocolate, fish and flesh are served for breakfast; which is no sooner over than Madeira,

Batavia. via is indeed fuch as to deter even Dutchmen, who can claret, gin, Dutch small beer, and English porter, are Batavia. refide at home with any comfort, from coming to it, laid out in the portico before the door of the great hall, and pipes and tobacco prefented to every guest, and a bright brass jar placed before him to receive the phlegm which the tobacco frequently draws forth. This occupation continues fometimes with little interruption till near dinner time, which is about one o'clock in the afternoon. It is not very uncommon for one man to drink a bottle of wine in this manner before dinner; and those who have a predilection for the liquor of their own country swallow several bottles of Dutch small beer, which they are told dilutes their blood, and affords plenty of fluids for a free perspiration. Immediately before dinner, two men flaves go round with Madeira wine, of which each of the company takes a bumper as a tonic or whetter of the appetite. Then follow three females, one with a filver jar containing water, fometimes rofe-water, to wash; a second with a filver bason and low cover of the fame metal, pierced with holes, to receive the water after being used; and the third with towels for wiping the hands. During dinner a band of music plays at a little distance : the musicians are all flaves, and pains are taken to instruct them. A confiderable number of female flaves attend at table, which is covered with a great variety of dishes; but little is received, except liquors, into ftomachs already cloyed. Coffee immediately follows dinner. The 24 hours are here divided, as to the manner of living, into two days and two nights; for each person retires, soon after drinking coffee, to a bed, which confifts of a mattrafs, bolfter, pillow, and chintz counterpane, but no sheets; and puts on his night drefs, or muslin cap and loose long cotton gown. If a bachelor, which is the cafe of much the greatest number, a female slave attends to fan him while he fleeps. About fix they rife, drefs, drink tca, take an airing in their carriages, and form parties to fpend the evening together to a late hour. The morning meetings confift generally of men, the ladies feldom choofing to appear till evening.

Few of these are natives of Europe, but many are descended from Dutch settlers here, and are educated with fome care. The features and outlines of their faces are European; but the complexion, character, and mode of life, approach more to those of the native inhabitants of Java. A pale languor overspreads the countenance, and not the least tint of rose is seen in any cheek. While in their own houses they dress like their flaves, with a long red checkered cotton gown defcending to the ankles, with large wide fleeves. They wear no head dress, but plait their hair, and fasten it with a filver bodkin on the top of the head, like the country girls in feveral cantons of Switzerland. The colour of their hair is almost universally black; they anoint it with the oil of the cocoa nut, and adorn it with chaplets of flowers. When they go abroad to pay vifits, or to take an airing in their carriages, and particularly. when they go to their evening parties, they drefs magnificently, in gold and filver spangled muslin robes, with a profusion of jewels in their hair, which, however, is worn without powder. They never attempt to mould or regulate the shape by any fancied idea of elegance, or any standard of fashion; and consequently formed a ftriking contrast with such few ladies as were lately arrived from Holland, who had powdered hair and fair complexions, had contracted their waifts with stays,

tavia. wore large head dreffes and hoops, and perfevered in the true, as the same accounts pretend, that the number of Batavia. early care of forcing back the elbows, chin, and shoulders. Every native lady is constantly attended by a female flave handsomely habited, who, as soon as her mifires is seated, fits at her feet before her, on the floor, holding in her hands her miftress's gold or filver box, divided into compartments, to contain areca nut, cardamom feeds, pepper, tobacco, and flacked lime; all which, mixed together in due proportions, and rolled within a leaf of betel, constitute a masticatory of a very pungent taste, and in general use. When in the public assemblies the ladies find the heat disagreeable, they retire to free themselves from their costly but inconvenient habits, and return without ceremony in a more light and loofe attire, when they are scarcely recognizable by ftrangers. The gentlemen follow the example; and throwing off their heavy and formal dreffes, appear in white jackets, fometimes indeed adorned with diamond buttons. The elderly gentlemen quit their periwits for nightcaps. Except in these moments the members of this government have always combined their personal gratification with the Eastern policy of striking awe into vulgar minds, by the assumption of exterior and exclusive distinctions. They alone, for instance, appear abroad in crimson velvet. Their carriages are diftinguished by peculiar ornaments. When met by others, the latter must stop and pay homage to the former. One of the gates of the city is opened only to let them pass. They certainly succeed in supporting absolute fway over a vast superiority in number of the descendants of the original inhabitants of the country, as well as of the flaves imported into it, and of the Chinese attracted to it by the hope of gain; those classes, though healthy, active, and as if quite at home, readily obeying a few emaciated Europeans. Such is the confequence of dominion once acquired; the prevalence of the mind over mere bodily exertions, and the effect of the combination of power against divided strength.

The native Javanese are in general too remote from civilization to have any wants that are not eafily fatisfied in a warm and fertile climate. No attempt is made to enflave their persons; and they find the government of the Dutch less vexatious than that of others, who divide some share of the sovereignty of the island with them. The fultan of Mataran rules to the east, the cmperor of Java in the centre, and the king of Bantam to the west; while the coast and effective power almost entirely belong to Holland. Those other sovereigns are descended from foreigners also; being Arabians, who imported the Mahometan religion into Java, and acquired the dominion of the country; a few inhabitants in the mountains excepted, who have preserved their independence and their faith, and among other articles that of the transmigration of souls. According to the Dutch accounts, nothing can be more tyrannic than those Mahometan rulers. The emperor is faid to maintain his authority by an army of many thousand men dispersed throughout his territories, beside a numerous female guard about his person. These military ladies are trained, it feems, to arms, without neglecting those accomplishments which may occasion a change in the occupation of fome among them, rendering them the companions, instead of being the attendants, of his Imperial majefty. This fingular institution may owe its origin to the facility of obtaining recruits, if it be

female births exceeds very confiderably that of males in

Most of the slaves are imported into it from Celebes and other eastern islands. They do not form a corps, or have any bond of union: nor is the general conduct of their owners towards them calculated to aggravate the misfortune of being the property of others. They are not forced to excessive labour. They have sufficient fustenance; but many of the males among them, who had formerly perhaps led an independent life till made captives in their wars, have been found to take offence against their masters upon very slight occasions, and to wreak their vengeance by affaffination. The apprehenfion of such an event is among the motives for preferring at Batavia female flaves for every use to which they can be applied; fo that the number purchased of them much exceeds that of the other fex. The flaves when determined on revenge often swallow, for the purpose of acquiring artificial courage, an extraordinary dole of opium, and foon becoming frantic as well as desperate, not only stab the objects of their hate, but fally forth to attack in like manner every person they meet, till felf-preservation renders it necessary to destroy them. They are faid in that flate to be running a muck; and instances of it are not more common among slaves than among free natives of the country, who, in the anguish for lofing their money, effects, and sometimes their families, at gaming, to which they are violently addicted, or under the pressure of some other passion or misfortime, have recourse to the same remely, with the same fatal effects.

In the country round Batavia the eye looks in vain for the common animals and vegetables which it had been daily accustomed to meet in Europe. The most familiar bird about the house of the embassador's host was the crown bird, as it was called at Batavia, which was not, however, the ardea pavonina of Linnzus, but the columba cristata, having nothing except its crest in common with the former. The same gentleman had alfo at his country house some large cassowary birds, which, though long in his possession, and having the appearance of tamenels, fometimes betrayed the fiercenels of their nature, attacking with their strong bill those who approached too near them. The vegetation of the country is likewife new. Even the parterres in the gardens are bordered, instead of boxwood, by the Arabian jessamine, of which the fragrant slowers adorn the pagodas of Hindostan. The Dutch, who are so fond of gardens in Holland, have transferred that tafte, where it can certainly be cultivated with more success, and indulge it to a great extent at their houses a little way from the city of Batavia; but still within that fenny diffrict, concerning which an intelligent gentleman upon the spot used the strong expression, that the air was pestilential, and the water poisonous. Yet the country is everywhere fo verdant, gay, and fertile; it is intersperfed with such magnificent houses, gardens, avenues, canals. and draw-bridges; and is so formed in every respect to please, could health be preserved in it—that a youth coming just from sea, and enraptured with the beauty of every object he faw around him, but mindful of the danger there to life, could not help exclaiming, "what an excellent habitation it would be for immortals !"

The most tolerable feason here is from March or A-

rest of the year. The sea breeze sets in about ten o'clock in the morning, and continues till four or five in the afternoon. It becomes then calm till feven or eight, when the land breeze commences, and continues at intervals till day break, followed by a calm for the remaining hours of the 24. Fahrenheit's thermometer was, in Batavia road, during the Lion's remaining there, from 86° to 88°, and in the town from 88° to 92°; but its variations by no means corresponded to the sensations produced by the heat on the human frame; the latter being tempered by any motion of the air, which circumstance has little effect upon the thermometer. Nor are the animal fufferings here from heat to be meafured by its intenfeness at any given moment of the day, but by its perfifting through the night; when, inthead of diminishing, as it does in colder countries, some. times 20 degrees, it keeps generally here within four or five of what it attains in the shade, when the sun is at its highest elevation.

The native Javanese derive, however, one advantage at least from an atmosphere not subject to the vicisfitudes of temperature experienced in the northern parts of Europe, where diseases of the teeth are chiefly prevalent; as they are here entirely exempt from fuch complaints. Their habit of living chiefly on vegetable food, and of abstaining from fermented liquors, no doubt contributes to this exemption; yet fuch is the caprice of taste, that jet black is the favourite colour and standard of beauty for the teeth amongst them, comparing to monkeys those who keep them of the natural colour. They accordingly take care to paint, of the deepest black, all their teeth, except the two middle ones, which they cover with gold leaf Whenever the paint or gilding is worn off, they are as attentive to replace it on the proper teeth, as the belies of Europe are to purify and

whiten theirs.

We have mentioned the rich vegetation of the country and the gardens which the Dutch have planted. In these gardens or orchards they cultivate the nutmeg, the clove, the camphor, and the cinnamon trees, together with the pepper plant, which creeping like a vine, is supported on a living tree. It is a species of the pepper plant that affords the leaf called betel, chewed fo univerfally by the fouthern Afiatics, and ferving for the inclosure of a few slices or bits of the areca, from thence erroneously called the betel nut. The areca nut tree is among the smallest of the tribe of palms, but comes next in beauty to the mountain cabbage tree of the West Indies; the latter differing chiefly in its fize and amazing height from the areca nut tree, the diameter of whole jointed trunk feldom exceeds four inches, or height 12 feet. But the fymmetry of each is perfect; the columns of a temple cannot be more regular than the trunk, which rifes without a branch, while the broad and fpreading leaves which crown the top form the ornamented capital. The areca nut, when dried, has some fimilitude in form and taste to the common nutmeg, but is of a less fize.

It would have been very extraordinary, and very culpable, in Sir George Staunton, and Dr Gillan physician to the embassy, if they had not, when on the spot, inquired into the truth of Foersch's account of the upas or poison tree of Java (see Poison Tree of Java, Enevel.) But the most minute inquiries were made re-

Batavia. pril to November; when the rains begin, and last the specting it; and the result of them was, that no such Batavi tree is known at Batavia, and certainly does not exist where Foersch has planted it. It is indeed a common opinion at Batavia, that there exists in that country a vegetable poison, which, rubbed on the daggers of the Javanese, renders the slightest wounds incurable; though some European practitioners have of late afferted that they had cured perions stabbed by those weapons, but not without having taken the precaution of keeping the wound long open, and procuring a suppuration. One of the keepers of the medical garden at Batavia affured Dr Gillan, that a tree diffilling a poisonous juice was in that collection, but that its qualities were kept fecret from most people in the settlement, lest the knowledge of them should find its way to the slaves, who might be tempted to make an ill use of it. In the same medical garden, containing it feems hurtful as well as grateful fubstances, is found also the plant from whence is made the celebrated gout remedy, or moxa of Japan, mentioned in the works of Sir William Temple, and defcribed in the Encyclopædia under the titles of ARTE-MISIA and MOXA.

> The whole country abounds with esculent fruits, and, amongst others, with the mangosteen, which is ripe in March, and is confidered as the most delicious of all fruits (see GARCINIA, Encycl.) Pine apples are in Java planted not in gardens, but in large fields; and are carried like turnips in heaps upon carts to market, and fold for confiderably less than a penny each, where money is cheaper than in England. It was a common practice to clean fwords, or other instruments of steel or iron, by running them through pine apples, as containing the strongest and cheapest acid for dissolving the rust that covered them. Sugar sold for about five-pence a pound. All forts of provisions were cheap, and the

ships crews fed on fresh meat every day.

The ferpents and noxious reptiles in Java have been mentioned elsewhere; but Sir George Staunton affures us, that not many accidents happen from them. Among the pagan Javanese, the crocodile, he says, is an object not only of fear, but also of religious veneration, to which offerings are made as to a deity. When a Javanese feels himself diseased, he will sometimes build a kind of coop, and fill it with fuch eatables as he thinks most agreeable to the croeodiles. He places the coop upon the bank of the river or canal, in the perfect confidence that, by the means of fuch offcrings, he will get rid of his complaints; and perfuaded, that if any perfon could prove fo wicked as to take away those viands, fueh person would draw upon himself the malady for the cure of which the offering was made. According to Sir George Staunton, Batavia road lies in 6° 10' fouth lat. and 106° 51' east long. from Greenwich.

BEER is a liquor fo palatable to the natives of Britain, and, when properly made, fo wholesome, especially in long voyages at fea, that Mr Thornton of East Smithfield obtained a patent, dated April 15. 1778, for inventing a method of reducing malt and hops to an effence or extract, from which beer may be made anywhere, either at sea or in distant countries. Though we do not perceive any great degree of ingenuity difplayed in this invention, yet as the account of it is

short, we shall lay it before our readers.

His method then of preparing an effence or extract of malt and hops is, by the transmitted heat of compreffed

Behens.

preffed vapour of boiling water, and a proper apparatus for that purpose. This apparatus may be made of iron, tin, or copper: it confifts of a boiler of any dimensions, a double veffel, and conducting tubes. The double veffel confifts of one vessel placed within another, and fitted tight at their rims. The upper veffel forms the upper part of the under veffel, and contains the liquor to be evaporated. The under vessel is everywhere inclosed, except at an aperture communicating with the boiler, and at another aperture communicating with the conducting tubes; and is conftructed fo as not to allow any part of the vapour condensed into drops within it to escape, except back again into the boiler: it is not fo extensive as to act as a common refrigeratory, and yet is capacious enough to prevent the liquor boiling over. The aperture communicating with the boiler is large enough to freely admit the vapour from the boiler

of the vapour in the under vessel being compressed, to a degree capable of transmitting to the liquor to be evaporated a proper heat, and at the same time to serve as a passage for more heat than is necessary to keep up that degree of compression. The conducting tubes are to convey this supersions heat or vapour, to be used

into the under veffel; and the aperture communicating

with the conducting tubes is of a proper fize to allow

for farther purposes, or immediately out of the build-ing.

BEETLE, an infect described in the Encyclopædia under the name given to it by naturalists, SCARABÆUS. Since that article was published, we have met with an account of a nondescript species, which is furnished with very fingular armour for its own defence. It was brought to M. Vaillant in the interior parts of Africa by a Nimiqua woman, and is by him called a fuperb beetle, not to be found in any cabinet of Europe. "While I was examining this beautiful infect (fays he) with attention, I felt my face fuddenly wetted by a cauftic liquor, of a very strong alkaline smell. The sprinkling was accompanied by a fort of explosion, loud enough to be heard at some distance. Unfortunately some of the liquor entered one of my eyes, and occasioned such insupportable pain, that I thought I should have lost the fight of it. I was obliged to keep it covered for feveral days, and bathe it from time to time with milk. In every part of my face that the alkaline liquor had touched, I felt the pain of a burn; and everywhere the skin changed to a deep brown, which wore out only by degrees and a long time after. This will not be surprifing to many, who already are acquainted with the fame property in feveral infects of the same genus; for instance, in that beautiful golden-green buprestis, which is so common in our kitchen-gardens in Europe: but as the infect of which I am here speaking is much larger, and inhabits a very hot country, it is natural that the effect produced by it should be more striking; tho' the liquor which our golden buprestis ejects at its enemy

occasions a very fensible smart, and its smell is consider- Begah ably pungent."

The naturalits Dorci and Olivier have given, in their Entomology, the figure of this African infect, which our author communicated to them, but they have given it erroneously. The human face, observable on its anterior corcelet in their figure, does not exist in nature; but M. Vaillant having given no figure of it himself, we cannot gratify our readers with a correct representation.

BEGAH, a land measure in Bengal, about one-third of an English acre.

BEHADER (Valiant), a title of honour conferred by the Mogul emperors upon either Mahomedans o Hindoos, and placed after their name or other title.

BEHEM (Martin), though hitherto little talked of, was one of the most enterprising men that ever lived, and deserves to have his name transmitted with reverence to the latest posterity. Born at Nuremberg, an Imperial city in the circle of Franconia, of a noble family not yet extinct, he had the best education which the darkness of that age would permit him to have; and the studies to which from his infancy he was most addicted, were those of geography, astronomy, and navigation. As he advanced in life, he often thought of the existence of the antipodes and of a western continent, of which he was ambitious to make the discovery

Filled with this great idea, in 1450 he paid a vifit to Isabella, daughter of John I. king of Portugal, at that time regent of the duchy of Burgundy and Flanders; and having informed her of his defigns, he procured a veffel, in which, failing westward, he was the first European who is known to have landed on the island of Fayal. He there established in 1460 a colony of Fle. mings, whose descendants yet exist in the Azores, which were for some time called the Flemish Islands. This eircumstance is proved, not only by the writings of contemporary authors, but also by the manuscripts preferved in the records of Nuremberg; from the Latin of which the following is translated: " Martin Behem tendered his fervices to the daughter of John king of Lusitania, who reigned after the death of Philip of Burgundy, furnamed the Good; and from her procured a ship, by means of which, having sailed beyond all the then known limits of the Western Ocean, he was the first who in the memory of man discovered the island of Fayal, abounding with beech trees, which the people of Lusitania call faye; whence it derived its name. After this he discovered the neighbouring islands, called by one general name the Azores, from the multitude of hawks which build their nests there (for the Lustanians use this term for hawks, and the French too use the word effos or efores in their pursuit of this game); and left colonies of the Flemish on them, when they began to be called Flemish Islands (A)."

Aften

⁽a) Although this record is contrary to the generally received opinion, that the Azores were discovered by Gonsalva Velho, a Portuguese, yet its authenticity seems unquestionable. It is confirmed not only by several contemporary writers, and by Wagenseil, one of the most learned men of the last century, but likewise by a note written on parchment in the German language, and sent from Nuremberg, a sew years ago, to M. Otto, who was then investigating the discovery of America. The note contained, with other things, the following sacts: "Martin Beham, Esq; son of Mr Martin Beham of Scoperin, lived in the reign of John II. king of Portugal, in an island which he discovered, and called the island of Fayal, one of the Azores, lying in the Western Ocean."

Eehem

After having obtained from the regent a grant of Fayal, and refided there about twenty years, Behem applied in 1484 (eight years before Columbus's expedition) to John II. king of Portugal, to procure the means of undertaking a great expedition towards the fouth west. This prince gave him some ships, with which he discovered that part of America which is now called Brazil; and he even failed to the Straits of Magellan, or to the country of some savage tribes whom he called Patagonians, from the extremities of their bodies being covered with a fkin more like a bear's paws than human hands and feet.

A fact fo little known, and apparently fo derogatory to the fame of Columbus, ought not to be admitted without fufficient proof; but the proofs which have been urged in support of its authenticity are such as cannot be controverted. They are not only the letters of Behem himself, written in 1486, and preferved in the archives of Nurenberg, but likewife the public records of that city; in which we read that " Martin Beliem, traverfing the Atlantic Ocean for feveral years, examined the American islands, and discovered the firait which bears the name of Magellan before either Christopher Columbus or Magellan failed those seas; whence he mathematically delineated, on a geographical ehart, for the king of Lusitania, the situation of the coast around every part of that famous and renowned ftrait long before Magellan thought of his expedition."

This wonderful discovery has not escaped the notice of contemporary writers. The following passage is translated from the Latin chronicle of Hartman Schedl: "In the year 1485, John II. king of Portugal, a man of a magnanimous spirit, furnished some galleys with provisions, and fent them to the fouthward, beyond the Straits of Gibraltar. He gave the command of this fquadron to James Canus, a Portuguefe, and Martin Behem, a German of Nurenberg in Upper Germany, descended of the family of Bonna: a man very well acquainted with the fituation of the globe; bleffed with a conflitution able to bear the fatigues of the fea; and who, by actual experiments and long failing, had made himself perfectly master with regard to the longitudes and latitudes of Ptolemy in the west. These two, by the bounty of Heaven, coasting along the Southern Ocean, and having croffed the equator, got into the other hemisphere, where, facing to the castward, their shadows projected towards the south and right hand. Thus, by their industry, they have opened to us another world hitherto unknown, and for many years attempted by none but the Genoese, and by them in vain. Having finished this cruize in the space of 26 months, they returned to Portugal with the loss of many of their feamen by the violence of the climate."

Belides this evidence of the first discovery of America having been made by Behem, we find the following particulars in the remarks made by Petrus Mateus on the canon law, two years before the expedition of Columbus': " Prima navigationes, &c. The first Christian voyages to the newly discovered islands became frequent under the reign of Henry, son of John, king of Lustania. After his death Alphonsus V. prosecuted the defign; and John, who fucceeded him, followed the plan of Alphonfus, by the affiftance of Martin Boliem, a very skilful navigator; to that in a short time the name of Luntania became famous over the whole world."

Cellarius; one of the most learned men o' his age, fays Behem expressly, " Behaimeus non modo, &c. Bothm did not think it enough to furvey the island of Fayal, which he first discovered, or the other adjacent islands which the Lustianians call Axores, and we, after the example of Bælim's companions, call Flemish islands, but advanced still farther and farther fouth, until he arrived at the remotest strait, through which Ferdinand Magellan, following his track, afterwards failed, and called it after

All these quotations, which cannot be thought tedious, fince they ferve to prove a fact almost unknown, feem to demonstrate, that the first discovery of America is due to the Portuguese and not to the Spaniards; and that the chief merit belongs to a German aftronomer. The expedition of Ferdinand Magellan, which did not take place before the year 1519, arose from the following fortunate circumstance: This person, being in the apartment of the king of Portuge!, faw there a chart of the coast of America drawn by Behem, and at once conceived the bold project of following the steps of this great navigator. Jerome Benzon, who published a defeription of America in 1550, speaks of this chart; a copy of which, fent by Behem himfelf, is preserved in the archives of Nuremberg. The celebrated astronomer Riccioli, though an Italian, yet does not feem willing to give his countryman the honour of this important discovery. In his Geographia Reformata, book. iii. p. 90. he fays, " Christopher Columbus never thought of an expedition to the West Indies until his arrival in the island of Madeira, where, amusing himself in forming and delineating geographical charts, he obtained information from Martin Boehm, or, as the Spaniards fay, from Alphonfus Sanchez de Huelva, a pilot, who had chanced to fall in with the island afterwards called Dominica." And in another place: "Let Boehm and Columbus have each their praise; they were both excellent navigators; but Columbus would never have thought of his expedition to America, had not Boehm gone there before him. His name is not fo much celebrated as that of Columbus, Americus, or Magellan, although he is fuperior to them all."

That Behem rendered fome very important fervices to the crown of Portugal, is put beyond all controverfy by the recompence bestowed on him by King John; of which the following account has been given to the public from the archives of Nuremberg. " In the year 1485, on the 18th of Feb. in Portugal, in the city of Allasavas, and in the church of St Salvador, after the mafs, Martin Behem of Nuremberg was made a knight, by the hands of the most puisfant Lord John II. king of Portugal, Algarve, Africa, and Guinea; and his chief fquire was the king himfelf, who put the fword in his belt; and the Duke of Begia was his fecond squire, who put on his right fpur; and his third fquire was Count Christopher de Mela, the king's cousin, who put on his left spur; and his fourth squire was Count Martini Marbarinis, who put on his iron helmet; and the king himself gave him the blow on the shoulder, which was done in the presence of all the princes, lords, and knights of the kingdom; and he espotsed the daughter of a great lord, in confideration of the important fervices he had performed; and he was made governor of the island of Fayal."

These marks of distinction, conferred on a stranger,

Behem. could not be meant as a recompense for the discovery of the Azores, which was made twenty years before, but as a reward for the discovery of Congo, from whence the Chevalier Behem had brought gold and different kinds of precious wares. This discovery made much greater impression than that of a western world made at the same time, but which neither increased the wealth of the royal treasury, nor satisfied the avariee of the

In 1492 the Chevalier Beliem, crowned with honours and riches, undertook a journey to Nuremberg, to visit his native country and his family. He there made a terrestrial globe, which is looked on as a masterpiece for that time, and which is still preserved in the library of that city. The outline of his discoveries may there be feen, under the name of western lands; and from their fituation it cannot be doubted that they are the prefent coasts of Brazil, and the environs of the Straits of Magellan. This globe was made in the same year that Columbus fet out on his expedition; therefore it is impossible that Behem could have profited by the works of that navigator, who besides went a much more northerly courfe.

After having performed feveral other interesting voyages, the Chevalier Behem died at Lisbon in July 1506, regretted by every one, but leaving behind him no other work than the globe and chart which we have just been speaking of. The globe is made from the writings of Ptolemy, Pliny, Strabo, and especially from the account of Mark Paul, the Venetian, a celebrated traveller of the 13th century; and of John Mandeville, an Englishman, who, about the middle of the 14th century, published an account of a journey of 33 years in Africa and Asia. He has also added the important discoveries made by himself on the coasts of Africa and America.

From these circumstantial accounts, but very lately brought to light, there can be little doubt, we think, but that America was discovered by Martin Behem. Dr Robertson is indeed of a different opinion: but great as we willingly acknowledge his authority to be, we may differ from him without prefumption, fince he had it not in his power to confult the German documents to which we have appealed, and has himfelf advanced facts not eafily to be reconciled to his own opinion. He allows that Behem was very intimate with Christopher Columbus; that he was the greatest geographer of his time, and scholar of the eelebrated John Müller, or Regiomontanus; that he had discovered, in 1483, the kingdom of Congo, upon the coast of Africa; that he made a globe which Magellan made use of; that he drew a map at Nuremberg, containing the partieulars of his discoveries; and that he placed in this chart land which is found to be in the latitude of Gniana. He adds indeed, without proof, that this land was a fabulous island; but if authentic records are to give place to bare affertion, there is an end of all historical evidence. If Beliem took for an island the first land which he discovered, it was a mistake furely not so gross as to furnish grounds for questioning his veracity, or for withholding from him for ever that justice which has been fo long delayed.

But this very delay will by some be thought a power-SUPPL. VOL. I. Part I.

ful objection to the truth of Behem's claim to the dif. Behem. covery of America; for if it was really discovered by him, why did not he leave behind him some writing to confirm the discovery to himself? and why did not the court of Portugal, fo jealous of the discovery of the new world, protest against the exclusive claim of the

I'o these objections we may reply, that, however plausible they may at first appear, they do not in the smallest degree invalidate the positive evidence which we have urged for the Chevalier Behem's being the real discoverer of the new world; for it would furely be very absurd to oppose the difficulty of assigning motives for certain actions performed at a remote period, to the reality of other actions for which we have the testimony of a cloud of contemporary witnesses. Suppposing it were true, therefore, that Behem had left behind him no writing claiming to himself the discovery of any part of the continent of America, the only inference which could be drawn from his filence would be, either that he was a man of great modelty, or that his mind was intent only on the acquisition of knowledge to himself, without feeling the usual impulse to communicate that knowledge to others. But it is not true that he has left behind him no claim of this discovery to himself. The letters to which we have appealed, and which are preserved in the archives of Nuremberg, together with the globe and map, which he certainly made, furnish as complete a confirmation of his claim as could have been furnished by the most elegant account of his voyages.

For the filence of the Portuguese, many reasons might be affigned. The discoveries of Columbus were made so much farther north than those of Behem, that, in an age when geographical knowledge was fo very limited, both Spaniards and Portuguese might very naturally believe that the country discovered by the former of these navigators had no connection with that discovered by the latter. At any rate, the Portuguese. whose discoveries proceeded from avarice, were satisfied with scraping together gold wherever they could find it; and finding it in Africa, they thought not of fearching for it in a more distant region, till the success of the Spaniards shewed them their mistake.

One thing more is worthy of attention. The long flay of Columbus at Madeira makes his interview with Behem more than probable. It is impossible that he should have neglected seeing a man so interesting, and who could give him every kind of information for the execution of the plan which he had formed. The mariners who accompanied the Chevalier Behem might also have spread reports at Madeira and the Azores concerning the discovery of which they had been witnesses. What ought to confirm us in this is, that Mariana fays himself (book xxvi. chap. iii.), that a certain veffel going to Africa, was thrown by a gale of wind upon certain unknown lands; and that the failors at their return to Madeira had communicated to Christopher Columbus the circumstances of their voyage. All authors agree that this learned man had some information respecting the western shores; but they speak in a very vague manner. The expedition of the Chevalier Behem explains the mystery (B).

BEREANS,

⁽B) For the greater part of this memoir we are indebted to M. Otto's paper on the discovery of America,

tants of Berea. They are highly commended in Scripture for their ready reception of the gospel, upon a fair and impartial examination of its agreement with the Old Testament prophecies. Sopater, a Berean, attended the apostle Paul to Asia. Acts xvii. 10-13. and xx. 4.

Bereaus, in modern church history, a fect of Protestant diffenters from the church of Scotland, who take their title from, and profess to follow, the example of the ancient Bereans, in building their fystem of faith and practice upon the Scriptures alone, without regard

to any human authority whatever.

The Bereans agree with the great majority of Chri-Doctrines. flians, both Protestants and Catholics, respecting the doctrine of the Trinity, which they hold as a fundamental article of the Christian faith; and they also agree in a great measure with the professed principles of both our established churches respecting predestination and election, though they allege that these doctrines are not confistently taught in either church. But they differ from the majority of all fects of Christians in various other important particulars. Such as,

1. Respecting our knowledge of the Deity. Upon this subject, they say, that the majority of professed Christians stumble at the very threshold of revelation; and, by admitting the doctrine of natural religion, natural conscience, natural notices, &c. not sounded upon revelation, or derived from it by tradition, they give up the cause of Christianity at once to the infidels; who may justly argue, as Mr Paine in fact does in his Age of Reason, that there is no occasion for any revelation or word of God, if man can discover his nature and perfections from his works alone. But this, the Bereans argue, is beyond the natural powers of human reason; and therefore our knowledge of God is from revelation alone; and that without revelation man would never have entertained an idea of his existence.

2. With regard to faith in Christ, and affurance of falvation through his merits, they differ from almost all other fects whatfoever. Thefe they reckon inseparable, or rather the same; because, they argue, God hath expressly declared, "He that believeth shall be saved;" and therefore it is not only abfurd, but impious, and in a manner calling God a liar, for a man to fay, " I believe the Gospel, but have doubts nevertheless of my own falvation." With regard to the various distinctions and definitions that have been given of different kinds of faith, they argue, that "there is nothing incomprehenfible or obscure in the meaning of this word as used in Scripture; but that as faith, when applied to human testimony, fignifies neither more nor less than the mere simple belief of that testimony as true, upon the authority of the testifier; so, when applied to the testimony of God, it fignifies precitely the belief of his testimony, and refling upon his veracity alone, without any kind of collateral support from concurrence of any other evidence or testimony whatever." And they infist, that as this faith is the gift of God alone, so the person to whom it is given is as conscious of possessing it, as the being to whom God gives life is of being alive; and

BEREANS, in ancient church history, the inhabi- therefore he entertains no doubts either of his faith or Bereans. his confequent falvation through the merits of Christ, who died and rofe again for that purpole. In a word, they argue, that the Gospel would not be what it is held forth to be, "glad tidings of great joy," if it did not bring full personal affurance of eternal salvation to the believer: which affurance, they infift, " is the prefent infallible privilege and portion of every individual believer of the Gospel." These definitions of faith, and its inseparable concomitant assurance, they prove by a variety of texts, which our room permits us not to

> 3. Confistently with the above definition of faith, they fay, that the fin against the Holy Ghost, which has alarmed and puzzled fo many in all ages, is nothing else but unbelief; and that the expression, that " it shall not be forgiven, neither in this world nor that which is to come," means only, that a person dying in infidelity would not be forgiven, neither under the former difpenfation by Mofes (the then prefent dispensation, kingdom, or government of God), nor under the Gospel dispenfation, which, in respect of the Mosaic, was a kind of

future world or kingdom to come.

4. The Bereans interpret a great part of the Old Testament prophecies, and in particular the whole of the Pfalms, excepting fuch as are merely historical or lauditory, to be typical or prophetical of Jefus Christ, his fufferings, atonement, mediation, and kingdom: and they efteem it a gross perversion of these Psalms and prophecies to apply them to the experiences of private Christians. In proof of this, they not only urge the words of the apostle, that " no prophecy is of any private interpretation," but they infift that the whole of the quotations from the ancient prophecies in the New Testament, and particularly those from the Psalms, are expressly applied to Christ. In this opinion many other classes of Protestants agree with them.

5. Of the absolute all-superintending sovereignty of the Almighty, the Bereans entertain the highest ideas, as well as of the uninterrupted exertion thereof over all works in heaven, earth, and hell, however unfearchable by his creatures. "A God without election (they argue), or choice in all his works, is a god without existence-a mere idol-a non-entity. And to deny God's election, purpose, and express will in all his works, is to make him inferior to ourselves." For farther particulars respecting the Berean doctrines, we must refer the reader to the works of Meffrs Barclay, Nicol,

Brookfbank, &c

The Bereans first affembled as a separate society of Christians in the city of Edinburgh in autumn 1773, and foon after in the parish of Fettercairn The opponeuts of the Berean doctrines alledge, that this new fystem of faith would never have been heard of, had not Mr Barclay, the founder of it, been disappointed of a fettlement in the church of Scotland. A respectable clergyman of the established church has even hinted fomething to this purpose in Sir John Sinclair's Statistical Account, Vol. IX. p. 599. But the Bereans, in answer to this charge, appeal not only to Mr Barclay's

doctrine.

hour.

Bereans. doctrine, uniformly preached in the church of Fettercairn, and many other places in that neighbourhood, for fourteen years before that benefice became vacant; but likewise to two different treatises, containing the same doctrines, published by him about ten or twelve years before that period. They admit, indeed, that, previous to May 1773, when the general affembly, by fultaining the king's presentation in favour of Mr Foote, excluded Mr Barclay from fucceeding to the church of Fettercairn (notwithstanding the almost unanimous defire of the parishioners), the Bereans had not left the established church, or attempted to erect themselves into a diffinct fociety; but they add, that this was by no means necessary on their part, until by the affembly's decision they were in danger of being not only deprived of his instructions. but of being scattered as sheep without a shepherd. And they add, that it was Mr Barclay's open and public avowal, both from the pulpit and the prefs, of those peculiar fentiments which now diffinguish the Bereaus, that was the first and principal, if not the only, cause of the opposition set on foot

ractice.

against his settlement in Fettercairn. Having thus given a concile view of the origin and distinguishing doctrines of Bereanism, it only remains to mention a few particulars relative to the practice of the Bereans as a Christian fociety. Infant baptism they confider as a divine ordinance inflituted in the room of circumcifion; and they think it abfurd to suppose that infants, who all agree are admissible to the kingdom of God in heaven, should nevertheless be incapable of being admitted into His visible church on earth. They commemorate the Lord's supper in general once amonth; but as the words of the inftitution fix no particular period, they fometimes celebrate it oftener, and fometimes at more distant periods, as may suit their general convenience. In observing this ordinance, they follow the primitive apostolic plan, without any previous days of fasting or preparation; as they apprehend that fuch human institutions only tend to make an idol of the ordinance, and to lead people to entertain erroneous ideas of its superior solemnity and importance. Equal and univerfal holiness in all manner of conversation, they recommend at all times, as well as at the table of the Lord. They meet every Lord's day for the purpose of preaching, praying, and exhortation to love and good works. With regard to the admission and exclusion of members, their method is very fimple. When any person, after hearing the Berean doctrines, professes his belief and affurance of the truths of the Gospel. and defires to be admitted into their communion, he is cheerfully received upon his profession, whatever may have been his former manner of life. But if fuch an one should afterwards draw back from his good profession or practice, they first admonish him; and if that has no effect, they leave him to himfelf. They do not think that they have any power to deliver up a backfliding brother to Satan. That text and other fimilar passages, such as, "Whatsoever ye shall bind on earth shall be bound in heaven," &c. they consider as restricted to the apostles and to the inspired testimony alone, and not to be extended to any church on earth, or any number of churches or of Christians, whether deciding by a majority of votes or by unanimous voices. Neither do they think themselves authorised, as a Christian church, to enquire into each others political opinions, any more

than to examine into each others notions of philosophy. They both recommend and practife, as Christian duties, fubmission to lawful authority; but they do not think that a man, by becoming a Christian, or joining their fociety, is under any obligation, by the rules of the Gospel, to renounce his rights of private judgment upon matters of public or private importance. Upon all fuch fubjects they allow each other to think and act as each may fee it his duty. And they require nothing more of their members than a uniform and fleady profeffion of the apostolic faith, and a suitable walk and conversation With regard to feet washing and the like practices, which some other fects of Christians confider as duties, the Bereaus are of opinion that they are by no means obligatory. They argue, that the example given by our Saviour of washing the feet of his disciples was not an institution of an ordinance, but merely a tamiliar inflance, taken from the custom of the country, and adopted by our Lord on that oceasion, to teach his followers that they ought at all times to be ready to perform even the meanest oflices of kindness to each

It may not be improper to add to the above delinea- Present tion of the principles and practice of the Bereans, that state. their doctrine has found converts in various places of Scotland, England, and America; and that they have congregations in Edinburgh, Glafgow, Paifley, Stirling, Crieff, Dundee, Arbroath, Montrofe, Fettercairn, Aberdeen, and other towns in Scotland; as well as in London and various places in England; not to add Pennsylvania, the Carolinas, and other States in Ame-

The above account of the doctrines, origin, practice, and present state of this society, has been given to us by the founder himself.

BERKENHOUT (Dr John), was about the year 1730 born at Leeds in Yorkshire, and educated at the grammar school in that town. His father, who was a merchant, and a native of Holland, intended him for trade; and with that view fent him at an early age to Germany, in order to learn foreign languages. After continuing a few years in that country, he made the tour of Europe in company with one or more Euglish noblemen. On their return to Germany they vifited Berlin, where Mr Berkenhout met with a near relation of his father's, the Baron de Bielfeldt, a nobleman then in high estimation with Frederick the Great king of Prusfia; diffinguished as one of the founders of the Royal Academy of Sciences at Berlin, and universally known as a politician and a man of letters. With this relation our young traveller fixed his abode for fome time; and, regardless of his original destination, became a cadet in a Prussian regiment of foot. He soon obtained an enfign's commiffion, and in the space of a few years was advanced to the rank of captain. He quitted the Pruffian fervice on the declaration of war between England and France in 1756, and was honoured with the command of a company in the fervice of his native country. When peace was concluded in 1760, not choosing, we fuppole, to lead a life of inactivity on half pay, he went down to Edinburgh, and commenced fludent of physic. During his residence at that university, he published his Clavis Anglica Lingua Botanica; a book of great utility to all students of botany.

Having continued some years at Edinburgh, Mr Ber-

Berken- kenhout went to the university of Leyden, where he was admitted to the degree of M. D. in the year 1765. On this occasion he published a thesis, intitled, Differtaio medica inauguralis de Podagra, which he dedicated to his relation Baron de Bielfeldt. Returning to England, Dr Berkenhout settled at Isleworth in Middlesex, and foon after published his Pharmacopaia Medici, the third edition of which was printed in 1782. In 1778 he was fent by government with the commissioners to America. Neither the commissioners nor their secretary were suffered by the congress to proceed surther than New York. Dr Berkenhout, however, found means to penetrate as far as Philadelphia, where the congress was then affembled. He appears to have remained in that city for some time without molestation: but at last they began to suspect that he was fent by Lord North for the purpole of tampering with some of their leading members. The Doctor was immediately seized and committed to prison.

How long he remained a state prisoner, or by what means he obtained his liberty, we are not informed; but we find from the public prints, that he rejoined the commissioners at New York, and returned with them to England. For this temporary faerifice of the emoluments of his profession, and in consideration of his having, in the fervice of his fovereign, committed himself to the mercy of a congress of enraged republicans, he

obtained a pension.

Many years previous to this event, Dr Berkenhout had published his Outlines of the Natural History of Great Britain and Ireland, in three volumes 12mo; a work which established his reputation as a naturalist. In the year 1773 he wrote a pamphlet, intitled, An Effay on the Bite of a Mad Dog, in which the Claim to Infallibility of the Principal Preservative Remedies against the Hydrophobia is examined. This pamphlet is inscribed to Sir George Baker, and deserves to be universally

In the year following Dr Berkenhout published his Symptomatology; a book which is too universally

known to require any recommendation.

At the beginning of the year 1788 he published a work, intitled, First Lines of the Theory and Practice of Philosophical Chemistry, which he dedicated to Mr Eden, now Lord Auckland, who had been one of the commissioners whom he accompanied to America.

These, we believe, are the Doctor's principal publications in the line of his profession; but he wrote on many other subjects with equal ability. His translation. of Count Teffin's Letters, which was his first publication, and dedicated to the present king when prince of Wales, evinces his knowledge of the Swedish language, and shews him to have been a good poet. His Effay on Ways and Means, proves him to have been better acquainted with the lystem of taxation than most other men who have written on the subject. His biographical powers appear in his Biographia Literaria; and in all his works are sufficient proofs of his classical learning, and that the Italian, French, German, and Dutch languages, were familiar to him. He possessed likewise a very confiderable degree of mathematical science, which he acquired in the course of his military studies; and to those more folid attainments he is faid to have added no small skill in the fine arts of painting and music. This eminent man, who, for the variety and promptitude of

his knowledge, has been compared to the Admirable Bernoulli Crichton, died on the 3d of April 1791. Bezout.

BERNOULLI (John), a celebrated mathematician, was born at Basil the 7th of August 1667. His sather intended him for trade; but his own inclination was at first for the belles lettres, which, however, like his brother James, whose life is given in the Encyclopædia, he lett for mathematics. He laboured with his brother to discover the method used by Leibnitz, in his effays on the differential calculus, and gave the fult principles of the integral calculus. Our author, with Meffrs Huygens and Leibnitz, is faid to have been the first who gave the solution of the problem proposed by James Bernoulli, concerning the catenary, or curve formed by a chain suspended by its two extremities. But for more on this subject, see ARCH in this Supplement.

John Bernoulli had the degree of doctor of physic at Bafil, and two years afterward was named professor of mathematics in the univerfity of Groningen. It was here that he discovered the mercurial phosphorus, or luminous barometer; and where he resolved the problem proposed by his brother concerning isoperimetricals.

On the death of his brother James, the professor at Bafil, our author returned to his native country, against the pressing invitations of the magistrates of Utrecht to come to that city, and of the university of Groningen, who wished to retain him. The Academic Senate of Basil soon appointed him to succeed his brother, without affembling competitors, and contrary to the effablished practice; an appointment which he held during his whole life...

In 1714 was published his treatife on the management of ships; and in 1730 his memoir on the elliptical figure of the planets gained the prize of the Academy of Sciences. The same Academy also divided the prize for their question concerning the inclination of the planetary orbits, between our author and his fon Daniel.

See BERNOULLI (Daniel), Encycl.

John Bernoulli was a member of most of the academies of Europe, and received as a foreign affociate of that of Paris in 1699. After a long life spent in conttant fludy and improvement of all the branches of the mathematics, he died full of honours, the 1st of January 1748, in the 81st year of his age. Of five fons which he had, three purfued the same sciences with himself. One of these died before him; the two others, Nicolas and Daniel, he lived to fee become eminent, and much respected in the same sciences.

The writings of this great man were dispersed through the periodical memoirs of feveral academies, as well as in many separate treatises. And the whole of them were carefully collected and published at Lausanne and Geneva, 1742, in 4 vols 4to. He was of undoubted eminence; but even in science he was a hasty man, and

certainly envious of the fame of Newton.

BETELGEUSE, a fixed star of the first magni-

tude, in the right shoulder of Orion.

BEZOUT (Stephen), a celebrated French matkematician, member of the Academies of Sciences and the Marine, and examiner of the guards of the marine and of the eleves of artillery, was born at Nemours the 31st of March 1730. In the course of his studies he met with some books of geometry, which gave him a talte for that seience; and the Eloges of Fontenelle, shewed him the honours attendant on talents and the

Blacklock.

Bezout, love of the sciences. His father in vain opposed the strong attachment of young Bezout to the mathematical sciences. April 8. 1758, he was named adjointmechanician in the French Academy of Sciences; having before that fent them two ingenious memoirs on the integral calculus, and given other proofs of his proficiency in mathematics. In 1763, he was named to the new office of examiner to the marine, and appointed to compose a system of mathematics for their use; and in 1768, on the death of M. Camus, he succeeded

as examiner of the artillery eleves.

Bezout fixed his attention more particularly to the resolution of algebraic equations; and he first found out the folution of a particular class of equations of all degrees. This method, different from all former ones, was general for the cubic and biquadratic equations, and just became particular only at those of the 5th degree. Upon this work our author laboured from 1762 till 1779, when he published it. He composed two courses of mathematics; the one for the marine, the other for the artillery. The foundation of these two works was the fame; the applications only being different, according to the two different objects: these courses have everywhere been held in great estimation. In his office of examiner he discharged the duties with great attention, care, and tenderness. A trait of his justice and zeal is remarkable in the following instance: During an examination which he held at Toulon, he was told that two of the pupils could not be prefent, being confined by the fmall-pox: he himfelf had never had that disease, and he was greatly afraid of it; but as he knew that if he did not fee these two young men, it would much impede their improvement, he ventured to their bed fides to examine them, and was happy to find them so deserving of the hazard into which he put himself for their benefit.

Mr Bezout lived in this employment for feveral years, beloved of his family and friends, and respected by all, enjoying the fruits and the credit of his labours. But the trouble and fatigues of his offices, with some personal chagrines, had reduced his strength and constitution; he was attacked by a malignant fever, of which he died Sept. 27. 1783, in the 54th year of his age, regretted by his family, his friends, the young stadents, and by all his ac-

quaintance in general.

The books published by him were: 1. Course of Mathematics for the use of the Marine, with a Treatise on Navigation, 6 vols in 8vo, Paris, 1764. 2. Course. of Mathematics for the Corps of Artillery, 4 vols in 8vo, 1770. 3. General Theory of Algebraic Equa-

tions, 1779.

His papers printed in the volumes of the Memoirs of the Academy of Sciences are: 1. On curves, whose rectification depends on a given quantity, in the volume for 1758. 2. On feveral classes of equations that admit of an algebraic folution, 1762. 3. First volume of a course of mathematics, 1764. 4. On certain equations, &c. 1764. 5. General resolution of all equations, 1765. 6. Second volume of a course of mathematics, 1765. 7. Third volume of the same, 1766. 8. Fourth volume of the same, 1767. 9. Intergration of differentials, &cc. vol. 3. Sav. Etr. 10. Experiments on cold, 1777.

BINOMIAL, a quantity confilling of two terms or members, connected by either of the figns + and -. See Algebra, def. o. Encycl.

Impossible or Imaginary BINOMIAL, is a binomial which

has one of its terms an impossible or an imaginary quan. Binomial

tity; as $a + \sqrt{-b}$.

BINOMIAL Curve, is a curve whose ordinate is expressed by a binomial quantity, as the curve whose ordinate is $n^a \times b + d n^c$ |e. Stirling, Method. Diff. p. 58.

BINOMIAL Line, or Surd, is that in which at least one of the parts is a furd. Euclid, in the tenth book of his Elements, enumerates fix kinds of binomial lines or furds,

> First binomial 3 + V 5, 2d binomial 18 + 4, 3d binomial V 24 + V 18, 4th binomial $4 + \sqrt{3}$, 5th binomial $\sqrt{6 + 2}$, 6th binomial $\sqrt{6+\sqrt{2}}$.

BINOMIAL Theorem. See ALGEBRA, Chap. VII. Sect. iii. (Encycl. Vol. I.); and Infinite SERIES, (Vol. XVII.) The reader who wishes for a fuller account of this famous theorem, may find it in Dr Hutton's Ma-

thematical Tracts, Vol. 1.

BIRD-CATCHING, is an art which, as it is practifed by means of bird-lime, nets, decoys, &c. has been fufficiently explained in the Encyclopædia. But there is another method of catching birds alive, by means of a fusee or musket, which was invented by M. Vaillant during his travels in Africa, and is sufficiently ingenious to

deserve a place here. It is as follows:

Put a smaller or larger quantity of powder into your fusce according as circumstances may require. Immediately above the powder place the end of a candle of fufficient thickness, ramming it well down; and then fill the barrel with water up to the mouth. When at a proper diffance you fire a musket thus loaded at a bird, you will only flun it by watering and moistening its feathers; and if you be alert, you may easily lay hold of it before it have time to spoil its plumage by fluttering. Our author admits, that in his first attempts he often put too much powder, or too thick a piece of candle into his fusee, or fired at too short a distance; and when any one of these mislakes was committed, he generally found the caudle entire in the animal's belly : but after a short apprenticeship he acquired sufficient skill to adjust matters so as that the water impelled by the powder went directly to the mark, whilst the tallow being lighter than the water fell short of it. If this method be indeed practicable (for not being sportsmen we have not made trial of it), it may on many occasions aid the refearches of the ornithologist.

BIRDS Nefts, in cookery. See Encycl. and CAP and

BUTTON in this Suppl.

BLACKLOCK (Dr Thomas) deferves, on fo many accounts, to have the principal incidents of his life recorded in this work, that to omit fuch an article from our lift of biographical fketches would be unpardonable negligence. We cannot, however, propose to write of him any thing which has not been written before, by an author who has repeatedly appeared before the public, and on each appearance has gained possession of the public heart. We shall therefore content ourselves with inferting in this place a short abridgment of the elegant account of the life and writings of Dr Blacklock, which was prefixed to that edition of his works which was published in 1793; and if we thus leffen our own labour, we are confcious that we shall at the same time increase the pleasure of our readers.

Thomas

Thomas Blacktock was in 1721 born at Anan, in the county of Dumfries in Scotland, but his parents were natives of the bordering county of Cumberland; fo that, though a native of Scotland, his descent was English. His father was a bricklayer, and his mother the daughter of a confiderable dealer in cattle. Both were respectable in their characters, and possessed, tho' moving in an humble sphere, a considerable degree of knowledge and urbanity. Their fon was not quite fix months old when he lost his eye fight in the small pox, which rendered him as complete a stranger to the vifible world as it he had been blind from the hour of his birth. It rendered him likewife incapable of learning any of the mechanical arts; and therefore his father kept him at home, and with the affiltance of some friends follered that inclination which, at a very early period, he shewed for books. This was done by reading to him first the simple fort of publications which are commonly put into the hands of children, and then feveral of our best authors, such as Milton, Spencer, Prior, Pope, and Addison. His companions, whom his early gentleness and kindness of disposition, as well as their compassion for his misfortune, strongly attached to him, were very affeduous in their good offices, in reading to instruct and amuse him. By their assistance he acquired fome knowledge of the Latin tongue, but he never was at a grammar school till at a more advanced period of Poetry was even then his favourite reading; and he found an enthufialtic delight in the works of the best English poets, and in those of his countryman Allan Ramfay. Even at an age so early as twelve he began to write poems, one of which is preferved in the collection that was published after his death, and is not perhaps inferior to any of the premature compositions of boys affifted by the best education, which are only recalled into notice by the future fame of their authors.

He had attained the age of nineteen when his father was killed by the accidental fall of a malt kiln belonging to his fon-in-law. This lofs, heavy to any one at that early age, would have been, however, to a young man possessing the ordinary means of support, and the ordinary advantages of education, comparatively light; but to him - thus suddenly deprived of that support on which his youth had leaned—destitute almost of every resource which industry affords to those who have the blessings of sight—with a body feeble and delicate from nature, and a mind congenially susceptible—it was not surprising that this blow was doubly severe, and threw on his spirits that despondent gloom to which he then gave way in the following pathetic lines, and which sometimes overclouded them in the subsequent period of

his life.

"Dejecting prospect! soon the hapless hour "May come; perhaps this moment it impends, "Which drives me forth to penury and cold,

- "Naked, and beat by all the storms of heav'n,
 "Friendless and guideless to explore my way;
 "Till, on cold earth this poor unshelter'd head
- "Reclining, vainly from the ruthless blast Retpite I beg, and in the shock expire."

He lived with his mother for about a year after his father's death, and began to be diftinguished as a young man of uncommon parts and genius. These were at that time unaffished by learning; the circumstances of

his family affording him no better education than the Blacklock. finattering of Latin which his companions had taught him, and the perufal and recollection of the few English authors which they, or his father in the intervals of his professional labours, had read to him. Poetry, however, though it attains its highest perfection in a cultivated foil, grows perhaps as luxuriantly in a wild one. To poetry, as we have before mentioned, he was devoted from his earliest days; and about this time several of his poetical productions began to be handed about, which confiderably enlarged the circle of his friends and acquaintance. Some of his compositions being shewn to Dr Stevenson, an eminent physician of Edinburgh, who was accidentally at Dumtries on a profeffional vifit, that gentleman formed the benevolent defign of carrying him to the Scotch metropolis, and giving to his natural endowments the affiftance of a classical education. He came to Edinburgh in the year 1741, and was enrolled a student of divinity in the university there, though at that time without any particular view of entering into the church. In that university he continued his studies under the patronage of Dr Stevenson till the year 1745, when he retired to Dumfries, and refided in the house of Mr M'Muido, who had married his fifter, during the whole time of the civil war, which then ra, ged in the country, and particularly diffurbed the tranquillity of the metropolis. When peace was restored to the nation, he returned to the university, and purfued his studies for fix years longer. During this last residence in Edinburgh, he obtained, among other literary acquaintance, that of the celebrated DAVID HUME, who attached himfelf warmly to Mr Blacklock's interests, and was afterwards particularly useful to him in the publication of the 4to edition of his Poems, which came out by subscription in London in the year 1756. Previously to this, two editions in 8vo had been published at Edinburgh, the first in 1746, and the second in

In the course of his education at Edinburgh, he acquired a proficiency in the learned languages, and became more a master of the French tongue than was then common in that city. For this last acquisition he was chiefly indebted to the social intercourse to which he had the good fortune to be admitted in the house of Provost Alexander, who had married a native of France. At the university he attained a knowledge of the various branches of philosophy and theology, to which his course of study naturally led, and acquired at the same time a confiderable fund of learning and information in those various departments of science and belles lettres, from which his want of sight did not absolutely preclude him.

In 1757, he began a course of study, with a view to give lectures in oratory to young gentlemen intended for the bar or the pulpit. On this occasion he wrote to Mr Hume, informed him of his plan, and requested his affistance in the prosecution of it. But Mr Hume doubting the probability of its success, he abandoned the project; and then, for the first time, adopted the decided intention of going into the church of Scotland. After applying closely for a considerable time to the study of theology, he passed the usual trials in the presbytery of Dumfries, and was by that presbytery licensed a preacher of the gospel in the year 1759. As a preacher he obtained high reputation, and was fond of com-

manufcript, as also a Treatise on Morals.

The tenor of his occupations, as well as the bent of his mind and dispositions, during this period of his life, will appear in the following plain and unftudied account, contained in a letter from a gentleman, who was then his most intimate and constant companion, the Rev. Mr Tameson, formerly minister of the Episcopal chapel at Dumfries, afterwards of the English congregation at Dantzic, and who lately refided, and perhaps yet refides,

at Newcastle upon Tyne.
"His manner of life (fays that gentleman) was so uniform, that the hiftory of it during one day, or one week, is the hiftory of it during the feven years that our perfonal intercourse lasted. Reading, music, walking, converfing, and disputing on various topics, in theology, ethics, &c. employed almost every hour of our time. It was pleafant to hear him engaged in a difpute, for no man could keep his temper better than he always did on fuch occasions. I have known him frequently very warmly engaged for hours together, but never could observe one angry word to fall from him. Whatever his antagonist might fay, be always kept his temper. 'Semper paratus et refellere sine pertinacia, et refelli sine iracundia.' He was, however, extremely senfible to what he thought ill utage, and equally fo whether it regarded himself or his friends. But his refentment was always confined to a few fatirical verses, which were generally burnt foon after.

" I have frequently admired with what readiness and rapidity he could fometimes make verfes. I have known him dictate from thirty to forty verses and by no means bad ones, as fast as I could write them; but the moment he was at a lofs for a thime or a verfe to his liking, he stopt altogether, and could very teldom be induced to finish what he had begun with so much ar-

This account fufficiently marks that eager fenfibility, chastened at the same time with uncommon gentleness of temper, which characterifed Dr Blacklock, and which indeed it was impossible to be at all in his company without perceiving. In the science of mind, this is that division of it which perhaps one would peculiarly appropriate to poetry, at least to all those lighter species which rather depend on quickness of feeling, and the ready conception of pleafing images, than on the happy arrangement of parts, or the skilful construction of a whole, which are effential to the higher departments of the poetical art. The first kind of talent is like those warm and light foils which produce their annual crops in fuch abundance; the laft, like that deeper and firmer mould on which the roots of eternal forests are fixed. Of the first we have seen many happy instances in that fex which is supposed less capable of fludy or thought; from the last is drawn that masculine fublimity of genius which could build an Iliad or a Paradife Loft.

Dr Blacklock could never dictate till he stood up; and as his blindness made walking about without asfistance inconvenient or dangerous to him, he fell infenfibly into a vibratory fort of motion of his body, which increased as he warmed with his subject, and was plea-fed with the conceptions of his mind. This motion at last became habitual to him; and though he could some-

appearance, fuch as preaching, he felt a certain unealinefs from the effort, and always returned to it when he could without impropriety. This appearance he deferibes in a short poem, in which he gives a ludicrous picture of himself; a picture indeed, of which, though the outlines are true, the general effect is greatly overcharged. Though his features were hurt, by the difease which deprived him of fight, there was a certain placid expression in his countenance, which marked the benevolence of his heart, and was calculated to procure to him individual attachments and general regard.

In 1762 he married Miss Sarah Johnston, daughter of Mr Joseph Johnston furgeon in Dumfries; a connection which formed the great folace and bleffing of his future life, and gave him, with all the tenderness of a wife, all the zealous care of a guardian and a friend. This event took place a few days before his being ordained minister of the town and parish of Kircudbright, in consequence of a presentation from the crown, obtained for him by the earl of Selkirk, a benevolent nobleman, whom Mr Blacklock's fituation and genius had interested in his behalf. But the inhabitants of the parish, whether from that violent aversion to patronage. which was then fo univerfal in the fouthern parts of Scotland, from fome political disputes which at that time fubfifted between them and his noble patron, or from those prejudices which some of them might naturally enough entertain against a pastor deprived of fight, or perhaps from all these causes united, were so extremely difinclined to receive him as their minister, that after a legal dispute of nearly two years, it was thought expedient by his friends, as it had always been wished by himself, to compromise the matter, by refigning his right to the living, and accepting a moderate annuity in its stead. With this slender provision he removed in 1764 to Edinburgh; and to make up by his industry a more comfortable and decent fublittence, he adopted the plan of receiving a certain number of young gentlemen as boarders into his house, whose studies in languages and philosophy he might, if necessary, assist. In this fituation he continued till the year 1787, when he found his time of life and state of health required a degree of quiet and repose which induced him to discontinue the receiving of boarders. In 1767 the degree of, doctor in divinity was conferred on him by the univerfity and Marischal college of Aberdeen.

In the occupation which he thus exercifed for fo many years of his life, no teacher was perhaps ever more agreeable to his pupils, nor master of a family to its inmates, than Dr Blacklock The gentleness of his manners, the benignity of his disposition, and that warm interest in the happiness of others which led him so conflantly to promote it, were qualities that could not fail to procure him the love and regard of the young people committed to his charge; while the fociety, which efteem and respect for his character and his genius often affembled at his house, afforded them an advantage rarely to be found in establishments of a similar kind

In this mixed fociety he appeared to forget the privation of fight, and the melancholy which it might at other times produce in his mind. He entered, with the cheerful playfulness of a young man, into all the fprightly narrative, the sportful fancy, and the humorous jest

Placklock, that rose around him. Next to conversation, music was perhaps the fource of his greatest delight; for he not only relished it highly, but was himfelf a tolerable performer on feveral instruments, particularly the flute. He generally carried in his pocket a small flageolet, on which he played his favourite tunes; and was not difpleased when asked in company to play or to sing them; a natural feeling for a blind man, who thus adds a fcene to the drama of his fociety.

Of the happiness of others, however, we are incompetent judges. Companionship and sympathy bring forth those gay colours of mirth and chearfulness which they put on for a while, to cover perhaps that sadness which we have no opportunity of witnessing. Of a blind man's condition we are particularly liable to form a miftaken estimate; we give him credit for all those gleams of delight which fociety affords him, without placing to their full account those dreary moments of darksome folitude to which the suspension of that society condemns him. Dr Blacklock had from nature a conflitution delicate and nervous, and his mind, as is almost always the case, was in a great degree subject to the indisposition of his body. He frequently complained of a lowness and depression of spirits, which neither the attentions of his friends, nor the unceasing care of a most affectionate wife, were able entirely to remove. The imagination we are so apt to envy and admire serves but to irritate this diforder of the mind; and that fancy in whose creation we fo much delight, can draw, from fources nuknown to common men, subjects of disgust, disquietude, and affliction. Some of his later poems express a chagrin, though not of an ungentle fort, at the supposed failure of his imaginative powers, or at the faltidiousness of modern times, which he despaired to please.

- "Such were his efforts, such his cold reward,
- 66 Whom once thy partial tongue pronounc'd a bard;
- " Excursive, on the gentle gales of spring,
- "He rov'd, whilst favour imp'd his timid wing;
- " Exhausted genius now no more inspires,
- "But mourns abortive hopes, and faded fires;
- "The short-liv'd wreath, which once his temples grac'd,
- " Fades at the fickly breath of fqueamish talle;
- "Whilst darker days his fainting slames immure
- "In chearless gloom and winter premature."

These lines are, however, no proof of "exhausted genius," or "faded fires." "Abortive hopes," indeed, must be the lot of all who, like Dr Blacklock, reach the period of old age. In early youth the heart of every one is a poet; it creates a scene of imagined happiness and delusive hopes; it clothes the world in the bright colours of its own fancy; it refines what is coarfe, it exalts what is mean; it fees nothing but difinterefledness in friendship, it promises eternal fidelity in love. Even on the diffresses of its situation it can throw a certain romantic shade of melancholy that leaves a man fad, but does not make him unhappy. But at a more advanced age, "the fairy visions fade," and he suffers most deeply who has indulged them the most.

About the time that these verses were written, Dr Blacklock was, for the first time, afflicted with what to him must have been peculiarly distressful. He became occasionally subject to deafness, which, though he seldom felt it in any great degree, was sufficient, in his si-

tuation, to whom the fense of hearing was almost the B'acklock only channel of communication with the external world, Bleaching to cause very lively uneafiness. Amidst these indispofitions of body, however, and disquietudes of mind, the gentleness of his temper never forfook him, and he felt all that refignation and confidence in the Supreme Being which his earliest and his latest life equally acknowledged. In summer 1791 he was seized with a severish diforder, which at first feemed of a slight, and never rote to a very violent kind; but a frame so little robust as his was not able to refit it, and after about a week's illness it carried him off on the 7th day of July 1791. His wife survives him, to feel, amidst the heavy affiction of his lofs, that melancholy confolation which is derived from the remembrance of his virtues.

The writings of Dr Blacklock confifted principally of poems, which were published in 4to in the year 1793; and to that edition was added, An Essay on the Education of the Blind, translated from the French of M. Hauy. But besides his avowed works, we have reason to believe that he was the author of many articles in the fecond edition of the Encyclopadia Britannica, though we cannot fay with certainty what those articles were. If our memory does not deceive us, we have been informed that the preface to that edition was furnished by him; and we have elsewhere attributed to him, on the best authority, the article BLIND, and the Notes to the article Music: but he undoubtedly contributed much more to the work, and was one of the principal guides of the proprietors.

BLEACHING. Since the article Bleaching in the Encyclopædia was written, very great improvements have been introduced into the art. Of these improve-

ments we shall proceed to give an account.

Mr Scheele of Sweden discovered the oxy-muriatic Discovery acid, or dephlogifticated muriatic acid, as he called it, of the oxy about the year 1774, and foon after observed its effects muriatic on vegetable colours. His method of procuring it was as follows: In a fand-bath is to be placed a glass retort, in which muriatic acid has been poured upon manganese; to this small receivers are to be adapted capable of containing about twelve ounces each, into which is to be poured about two drachms of water, without any other lute than a flip of blotting-paper about the neck of the retort. In about a quarter of an hour a yellow air is perceived in the receiver, which is to be taken off. If the paper has been properly applied, the air rushes out forcibly; the receiver must be quickly stopped, and another applied. Thus many receivers may be filled with the dephlogisticated muriatic acid; but it is necessary to place the retort in such a manner that the drops which rife into its neck may be able to fall back. The water ferves to retain the vapours of the acid. "I use (says he) many receivers, that I may not be obliged to repeat a fimilar distillation for every experiment. It is not proper to employ large ones, because every time they are opened, a great part of the acid is diffipated in the air. What I submitted to examination with this dephlogisticated muriatic acid was placed in the neck of the receiver, which I had flopped. The cork was turned yellow, as by aquafortis. Paper tinged with turnfol became almost white; all red, blue, and yellow flowers, as also green plants, turned yellow in a short time, and the water in the receiver was chankalis nor acids were able to restore the colours of the

flowers, or of the plants."

M. Berthollet, in 1785, proved that this acid was composed of muriatic acid combined with oxygen; and that when it had deprived vegetable matters of their colour, it was reduced to the state of common muriatic acid; that is, it had lost the oxygen with which it was united. This oxygen had combined with the colour-I applicaing particles of the vegetable matter, and had rendered them colourless. After making these observations, it l aching. occurred to him that the oxy-muriatic acid might produce the same effect upon those particles which give colour to thread and cloth, and which it is the object of bleaching to destroy. "At first (fays he) I made use of water highly impregnated with this acid; and I renewed it when it was exhausted, until the thread or cloth appeared white; but I foon perceived that they were confiderably weakened, and that they were entirely losing their folidity. I then weakened the liquor a little, and I succeeded in bleaching cloth without damaging it. But it speedily became yellow by keeping, especially if it was warmed, or passed through an alkaline ley. I reflected upon the circumstances of common bleaching, and I endeavoured to imitate its process, because I thought the oxygenated muriatic acid might act in the same manner as the exposition of the cloth in the meadows, which alone does not fuffice, but which appears only to dispose the colouring parts of the cloth to be diffolved by the alkali of the ley. I examined dew, not only that which falls from the atmofphere, but also that which comes from the nocturnal transpiration of plants; and I observed that both of them were impregnated with oxygen, fufficiently to deftroy the colour of paper flightly tinged with turnfol.

"I therefore employed leys, and the action of oxygenated muriatic acid, alternately, and I then obtained a permanent white; and as, at the finishing of the common bleaching, the cloth is paffed through four milk, or through fulphuric acid diluted with a very large quantity of water, I also tried passing the cloth through a very dilute folution of fulphuric acid, and I observed that the white was thereby rendered more clear. As foon as I made use of the leys intermediately, I found that it was not necessary to employ a concentrated liquor, or to let the cloth, at every immersion, remain long therein: by this I avoided two inconveniences, which would have rendered this process impossible to be practifed in the large way. The first is the suffocating odour of the liquor, which it would be very inconvenient, and even dangerous, to respire for any length of time, and which has discouraged many persons who tried to use it; the second is, the danger of weakening the cloth. I now also left off mixing any alkali with the oxygenated muriatic acid, as I had practifed in the

greatest part of my first trials.

"This is nearly the ftate in which my experiments were, when I made fome trials in the prefence of the celebrated Mr Watt. A fingle view fufficed for a philosopher whose genius has been exercised so long upon the arts. In a short time Mr Watt wrote to me from England, that even in the first operation he had bleached five hundred pieces of cloth at Mr Grigor's, who has a large bleaching ground at Glasgow, and who continues to make use of the new process. In the mean

SUPPL. YOL. I. Part I.

time M. Bonjour, who had hitherto affifted me in my Bleaching. experiments, and who joins great fagacity to a most extended knowledge of chemistry, affociated himself with Mr Constant, at Valenciennes, in order to form an establishment in the state of the state of

blishment in that city."

M. Caillau made a great number of experiments at Paris respecting this new mode of bleaching; but the greatest part of these experiments was made upon cotton, which is more easy to bleach, and does not require leys fo often or fo ftrong as flax or hemp. He also went to St Quentin, to perform the operation upon the cloth of that country; but he found that all the cloths, which he had bleached to the fatisfaction of the manufacturers, became again of a reddish colour when they were exposed to a common ley, or even when they were left for some time in a warehouse. Several similar complaints were made by other persons; and M. Berthollet himself had observed the same thing in his own experiments. M. Bonjour, however, and M. Welter, affirmed that the cloth which they had bleached preferved its colour perfectly. M. Berthollet foon found, that the imperfection in his bleaching was owing to the manner in which he had used the leys. "I had contented my- Ann. de felf (fays he), in those trials on small pieces which I Chym. II. made in my laboratory, to pour the hot alkaline folu-158. tion into a veffel where I placed the pieces; it there became cool very rapidly, and therefore did not act with sufficient power; but when I let these pieces remain in the liquor, which I kept nearly in a boiling heat during the space of two or three hours, they were then no longer subject to the above-mentioned defects: it was therefore merely the weakness of the leys which had occasioned the accidents which were experienced by Meffrs Caillau, Décroifille, and myself. It is necessary that the colour of the cloth should not be changed by the last ley, and this is the surest mark that the bleaching is finished; nevertheless, after this last action of the

in the bleaching liquor.

"After this last immersion, it is necessary to plunge the cloth in four milk, or in water acidulated with sulphuric acid. I do not know the most convenient proportion of sulphuric acid; but it appeared to me that we might successfully, and without danger, make use of one part, in weight, of this acid to fitty of water. We must keep the cloths during about half an hour in this liquor warmed; after which it is proper to squeeze them well, and plunge them directly into common water; for if the evaporation should take place, the sulphuric acid, becoming thereby concentrated, would corrode them. The cloths being then well washed, require only to be dried and dressed in the ordinary man-

ley, it is proper to put the cloth, for a few moments,

ner, according to their different forts.

"It is of the utmost importance to take care that the water is not too strongly impregnated with the sulphuric

"The bleaching of cotton cloth is much easier and shorter; two leys, or at most three, and as many immersions in the bleaching liquor, are sufficient for them. As they are bleached so easily, it is advantageous, when there are slaxen, hempen, and cotton cloths, to be bleached, to reserve for the cotton the liquors which have been previously weakened by the cloths of slax or hemp; for it is economical to exhaust the liquors as much as possible, and those which are considerably

Bleaching. weakened still suffice for the cotton, although they have fearcely any action upon hemp or flax.

"Thread, in the common way of bleaching, is attended with a far greater number of difficulties than cloth; because of the immense number of surfaces which it is necessary to present successively to the action of the atmosphere. Some part of these difficulties occur in bleaching with the oxygenated muriatic acid; neverthelefs, in the end, it is more advantageous with respect to thread than with respect to cloth. Mr Welter has formed at Lisle, with two partners, an establishment for bleaching thread, with great fuccess, and he has already begun fome others. He has found that ten or twelve leys, and as many immersions, are required for some forts of thread; and, that the thread may be furrounded with the liquor, it is necessary to place it, quite loofely, in a basket, which permits the liquor to penetrate to all its furfaces; when the liquor is much weakened, it is still fit to be used for the bleaching of cotton.

"I had, in the beginning of my experiments, tried whether the vapour would not be preferable to the oxygenated muriatic acid in a liquid flate, and I observed that it bleached with greater quickness; but, whatever precautions I employed, it appeared to me that a confiderable loss of it took place; that those parts of the cloths which were the most exposed to it were subject to be weakened; and that it was more difficult to ob-

tain an equal whiteness throughout.

"To prevent all the accidents which may refult from the liquor acting with too great power, it is important to have a means of measuring its force. M. Decroisile thought of using, for that purpose, a solution of indigo in fulphuric acid. He takes one part of indigo, reduced into fine powder, and eighteen parts of concentrated fulphuric acid; this mixture is put into a matrafs, which is kept, during fome hours, in a waterbath; when the folution is finished, it is diluted with a thousand parts of water. To try the power of the oxygenated muriatic acid, one measure of this folution is put into a graduated glass tube, and some of the liquor is gradually added to it, until the colour of the indigo is destroyed. We must first determine how many measures of a liquor, the goodness of which has been afcertained by experiments made upon'cloth, are necessary to destroy the colour of one measure of the folution of indigo, and this number will ferve to eftimate the respective strength of all the liquors which it may be necessary to compare with it. M. Watt employs, in the same manner, a folution of cochineal."

Method of M. Berthollet recommended the following method procuring of procuring the oxy-muriatic acid: "If we have good the acid for oxyd of manganefe, formed in small crystals, and conbleaching. taining but little extraneous matter, the proportions of the substances to be submitted to distillation are the following: Six onnees of caix of manganese reduced to powder; one pound of common falt, also reduced to powder; twelve ounces of concentrated sulphuric acid, or oil of vitriol; from ten to twelve ounces of

water.

"When these materials are prepared, we must carefully mix the oxyd of manganese with the common salt, and introduce the mixture into the distilling vessel placed upon a sand bath: we must then pour upon it the sulphuric acid, previously diluted (and of which the heat occasioned by its mixture with water is dislipated), and

immediately apply to the mouth of the matrass the Bleaching tube which is to conduct the gas into the intermediate vessel.—It must not be forgot, that in this operation

the lutes require particular attention.

"The fize of the veffels should be such, that the distilling matrass may be about one third empty; and, for the quantity above mentioned, the tub should hold 100 quarts of water; there should also be an empty space of about 10 quarts, in order that when the gas lodges itself in the cavities intended to receive it, the water may have a free space to rise in.

"Before the commencement of the operation, the pneumatic tub must be filled with water. The mixture being made, the gas, which very foon begins to difengage itself, drives out the atmospherical air which is in the apparatus: when it is judged that the atmospheric air has passed into the cavities, it is to be drawn off by means of abent tube, which is to be introduced fucceffively under each cavity: to drive out the water which has entered into the tube, this last is to be forcibly blown into. The operation is then suffered to go on without fire until it is perceived that the bubbles come over but flowly: then a little fire is to be applied, which is not to be hastily increased at the beginning, but may be gradually angmented, fo that at the end of the operation the matter may be brought to a boiling state. It is known to be nearly finished when the tube by which the gas is disengaged, and the intermediate vessel, become hot. When the gas is difengazed only in a small quantity, the fire may be withdrawn; and when the diffilling veffel retains but a gentle warmth, it is to be unluted, and warm water is to be poured upon the refidue, that it may remain in folution, and thereby be more eafily poured out.

"The operation is longer or shorter according to the quantity of materials: with that above mentioned, it should last five or fix hours; it is proper not to hasten it, that a larger quantity of gas may be drawn off. A single person is able to manage several distillations at the same time; to each of which may be given much larger quantities of materials than those which have been

pointed out.

"The intermediate veffel by degrees becomes filled with a liquor which is pure, though weak, muriatic acid; neverthelefs, we may perform the operation feveral times without extracting it: but when it is supposed that there is not sufficient empty space, this acid is to be drawn off by means of a syphon, and, when we have collected a sufficient quantity of it, it may be substituted for the mixture of vitriolic acid and common salt in the operation we have described, if we have no other use to make of it. That there may pass but a small quantity of muriatic acid, not oxygenated, the first tube ought to form a right angle, or even an obtuse one, with the body matrass.

"During the operation, the agitator must be from time to time put in motion, to favour the absorption of the gas by the water: when it is finished, the liquor is of a proper strength to use in bleaching; or we may put a less quantity of water in the tub, and then dilute the liquor according to the proportion already

mentioned.

"In this state of concentration, although the liquor has a pretty strong odour, it nevertheless is not hurtful, nor even very unpleasant, to those who use it; it is, however,

aching however, proper to conduct it into the troughs where the cloths are placed by means of wooden canals, which are to be connected with the faufet or tube which is at the lower part of the tub."-The following is a de-

feription of the apparatus:

ABCD is a reverberatory furnace, having, on a line with B, many small openings in its circumference, to serve as chimneys; within which, upon a faud-bath a, is placed a matras b, the neck of which stands out above the furnace, running thro' the opening D, which is to be closed with clay. The mouth F, of the neck of the matrals, is closed by a cork G, through the middle of which paffes a tube H, which forms a communication between the infide of the matrafs b, and the intermediate veffel K, where it also passes through a cork I, which closes one of the three openings of that vessel. The corks G and I ought to be prepared before-hand, and well fitted to each end of the tube of communication H, which is to be fo disposed that it may be fitted in immediately after the mixture is made in the matrafs.

The intermediate vessel K is about an eighth part full of water; into it is plunged the tube of fafety L, to prevent danger from regurgitation. This tube ought to be so high, that the weight of the water which enters into it, by the pressure of the gas, may be great enough to cause the gas to pass into the pneumatic tub NOP, by the tube of communication M, which is plunged therein, and reaches to the bottom, where it is bent horizontally, fo that the gas may be emitted under the first of the three wooden, or (if they can be procured) stone-ware, cavities, or receivers, which are placed in the infide of the tub, one above the other. O is a handle which serves to turn the agitator E, the movement of which facilitates the combination of the gas with the water. P is a spigot and fauset to draw

off the liquor.

A thod of It is necessary to prepare the cloth by leaving it to b ching. foak for 24 hours in water, or, which is better, in some old ley. Afterwards it should be submitted to the action of one or two good leys; because all the colouring part which may be extracted by the leys would else, without any advantage, confume a part of that liquor which it is important to be as sparing of as possible. After this, the cloth is to be carefully washed; then it is to be placed in the troughs, without any part being preffed or confined, in fuch a manner that it may be thoroughly impregnated with the liquor which is to run thereon. The troughs, as well as the tub, ought to be constructed without iron; for that metal, being rusted by the oxygenated muriatic acid, would produce iron moulds, which could not be taken out but by means of falt of forrel.

The first immersion ought to be longer than the others; it may be continued for three hours, after which the cloth is to be taken out; it is to be again submitted to the action of ley, and then placed in a trough, that fresh liquor may be poured thereon: it is fufficient that this immersion, and the following ones, continue half an hour. When the cloth is taken from the trough, the liquor is to be wrung out, it is to be again submitted to the ley, and afterwards to fresh immersions. The same liquor may serve until its strength is exhausted: when it is much weakened, there may be fome fresh liquor added to it. When the cloth appears white, except fome black threads and the lifts, it Bleaching. is to be impregnated with black foap, and then frongly rubbed; after which it is to be submitted to the last ley and the last immersion. We cannot determine what number of leys and immersions may be necessary, because it varies according to the nature of the cloth: nevertheless, the limits of this number are between four and eight for linen or hempen cloths.

The manufacturers at Javelle, to whom M. Berthollet had communicated this process, soon after published, in different journals, that they had discovered a particular liquor which had the property of bleaching cloth

by an immersion of some hours only. The change they had made in the process performed in their presence. confisted in putting some alkali into the water which receives the gas; this enables the liquor to become

much more concentrated, so that it may be diluted with several times its own quantity of water before it

"These are the proportions which yielded me (fays Berthollet) a liquor fimilar to the pretended Javelle ley; two ounces and a half of common falt, two ounces of fulphuric acid, fix drachms of calx of manganese, and, in the veffel where the gas is to be concentrated, one pound of water, and five ounces of potash, which should be diffolved in the water. The Javelle liquor has a fomewhat reddish appearance, occasioned by a small quantity of manganese, which either passes in the distillation, because an intermediate vessel is not used, or exists in the potass; most kinds of which contain it, as I have well convinced myfelf."

." This liquor may be diluted with from ten to twelve parts of water; and, after this, it bleaches more speedily than the liquor itself: but without speaking of the imperfections of the method which is described in the publications from Javelle, and which can only inffice for cotton, we are not able to bleach near the same quantity of cloth with the oxygenated muriatic acid combined in this manner with an alkali, as might be bleached with the fame quantity of that acid mixed with water alone; because there is formed a portion of that neutral falt which is known at prefent by the name of oxygenated muriate of potals, and in which the oxygen becomes concentrated. Now all the oxygen

ed ufeless for bleaching; because the oxygenated muriate of potash does not destroy colours."

This method of bleaching was very foon adopted in Britain, and is now almost universal among bleachers. A great many changes have been made in the process: one of the most important of which is substituting lead veffels for wooden ones, which, befides weakening its action exceedingly, were very foon deftroyed by the acid. We believe, too, that the bleachers very gene-

which enters into the composition of this salt is render-

rally add fome alkali to the acid, notwithstanding the ftrong objections which Mr Berthollet has made to that

manner of bleaching.

This method of bleaching has been found to answer remarkably well: the only objection that has been made to it is, that the cloth is apt to be weakened. And this, no doubt, must be the case, if care be not taken to prevent the acid from being too much concentrated; but we have little doubt that, with a sufficient degree of caution, it will prove as face as any other whatever;

Bleaching, and, in point of expedition, there cannot furely be any comparison drawn between the old mode of bleaching and the new.

Theory of

It remains for us now to consider, whether the new bleaching. discoveries in chemistry do not throw some rays of light upon the theory of bleaching; for it is only by perfecting the theory that we can advance with certainty in our practical improvements.

> It has been already observed, in the article BLEACH-ING (Encycl.), that cloth, after being bleached, was a good deal lighter than it had been before that operation: It follows, therefore, that it must have been deprived of fomething during the bleaching. Cloth bleached by means of the oxy-muriatic acid likewise undergoes a loss of weight; so that, in all probability, both

modes act in precifely the same manner.

If raw linen or thread be boiled in a folution of cauftic alkali, properly diluted, it gives out fomething which tinges the ley of a deep brown, and at the fame time the alkali lofes its causticity. If the linen be boiled in another fimilar folution, it communicates the fame colour, and even a third may be flightly tinged; but after this, alkalis, unless so much concentrated as to injure the texture of the cloth, have no effect on it whatever. If the linen be now plunged into oxy-muriatic acid, properly prepared, and allowed to remain till it begins to become white, and then plunged into an alkaline ley, the alkali lofes its causticity, and affumes the same deep colour that the first ley did. Here, then, we have two alkaline folutions; the one faturated with colouring matter before the action of the oxy-muriatic acid on the linen, the other after it. When these folutions are faturated with an acid, a yellow coloured precipitate is obtained, which when dried assumes the appearance of a black powder. Precifely the same substance is obtained from both folutions. This colouring matter is almost infoluble in water. Pure or caustic potass diffolves about double its own weight of it; carbonate of potass not so much.

Hence we see the use of alkalis in bleaching. The colouring matter is not soluble in water, but part of it is foluble in alkali. However, after the alkali has exhausted all its power, the linen is not white: colouring matter, therefore, exists in it, which alkalis cannot act upon. But after being plunged in oxy-muriatic acid, it also becomes soluble in acids. Here, then, is the use of that acid in bleaching-it communicates fomething to the colouring matter which renders it foluble in alkali. This fomething, we have already feen, is oxygen. It follows, therefore, that before the greater part of the colouring matter of linen can be extracted by alkalis, it must be combined with oxygen. It is in producing this combination that the use of the exposure to the fun and air consists; and it is because the oxy muriatic acid produces it almost instantaneously, that the new mode of bleaching is fo much more expeditious than

If into the alkaline folution of the colouring matter lime-water be poured, there takes place a copious precipitate, which confifts of the lime and colouring matter combined. Lime, therefore, has a stronger affinity for the colouring matter than alkali has: and as the compound of lime and the colouring matter is not very foluble in water, lime-water might be used to de-

prive the alkaline ley of the colouring matter which it Bleaching has imbibed; after which it might be used again. Care, however, must be taken that no lime-water remains in the ley; otherwise it might precipitate and fix the colouring matter on the linen, after which it would be very difficult to remove it.

From an alkaline ley, faturated with the colouring Nature of matter of linen yarn, Mr Kirwan, by means of muriatic the colour. acid, precipitated the colouring matter. He found it to of linen. possess the following properties: When suffered to dry for some time on a filter, it assumed a dark green colour, and felt somewhat clammy like moist clay. "I Irish Trans took (fays he) a small portion of it, and added it to 60 1789. times its weight of boiling water, but not a particle of it was diffolved. The remainder I dried in a fand heat; it then affumed a shining black colour, became more brittle, but internally remained of a greenish yellow, and weighed one ounce and a half.

"By treating eight quarts more of the faturated ley in the same manner, I obtained a further quantity of the greenish deposit; on which I made the following

experiments:

"1st, Having digested a portion of it in rectified spirit of wine, it communicated to it a reddish hue, and was in a great measure dissolved: but by the affusion of distilled water the solution became milky, and a white deposit was gradually formed; the black matter diffolved in the same manner.

" 2dly, Neither the green nor the black matter was foluble in oil of turpentine or linfeed oil by a long con-

tinued digestion.

"3dly, The black matter being placed on a red-hot iron, burned with a yellow flame and a black smoke,

leaving a coaly refiduum.

"4thly, The green matter being put into the vitriolic, marine, and nitrous acids, communicated a brownish tinge to the two former, and a greenish to the lat-

ter, but did not seem in the least diminished.

" Hence it appears, that the matter extracted by alkalis from linen yarn is a peculiar fort of refin, different from pure refins only by its infolubility in effential oils, and in this respect resembling lacs. I now proceed to examine the power of the different alkalis on this fubstance. Eight grains of it being digested in a solution of crystallized mineral alkali, saturated in the temperature of 60°, inftantly communicated to the folution a dark brown colour; two measures (each of which would contain 11 pennyweights of water) did not entirely diffolve this substance. Two measures of the mild vegetable alkali diffolved the whole.

"One measure of caustic mineral alkali, whose specific gravity was 1,053, diffolved nearly the whole, lea-

ving only a white refiduum.

"One measure of caustic vegetable alkali, whose specific gravity was 1,039, diffolved the whole.

"One measure of liver of sulphur, whose specific gravity was 1,170, dissolved the whole.

" One measure of caustic volatile alkali dissolved also a portion of this matter."

The colouring matter of cotton is much more foluble in alkali than that of linen; hence the greater facility

with which cotton is bleached. From these observations, the great importance of alkalis in bleaching, and the necessity of regulating the

strength,

eaching firength, and afcertaining the purity, of the leys made use of, must be apparent. Manufacturers, therefore, lie under very great obligations to Mr Kirwan, who has lately examined the alkaline matters used in bleeching with his usual accuracy and abilities. The result of his experiments was as follows:

if Trans. Table of the quantity of mere alkali in 100 Avoirdupois 89. pounds of the following substances.

One hundred lbs.		Mineral .	Alkali
Crystallized foda	- 1	20 ll	OS.
Sweet barilla -	10	24	
Mealy's cunnamara kelp	-	3,4	37

Clarke's refined ash -		26,8	75
Cashup -	m1	19,3	76
Common raw Irish weed-ash		1,6	66
Ditto slightly calcined	13	4,6	66

When linen is allowed to remain for some time in oxy-muriatic acid, it becomes white. It is evident, then, that when the colouring matter of linen is faturated with oxygen, it becomes colourless: But linen bleached in this manner very foon becomes yellow, especially when exposed to heat. Berthollet, to whose ingenious experiments and observations we are indebted for the greater part of the above remarks, has given the following explanation of the cause of this change: He distilled the colouring matter of linen, and obtained a thick oil, a little aminonia, and $\frac{1}{100}$ of carbon remained behind. The oil contained carbon; and he suppofed that carbonic acid gas, and carbonated hydrogen gas, were disengaged. He concluded in consequence, that one-third of this colouring matter was carbon. The other ingredient in the oil was hydrogen; for Lavoisier has proved that oil is composed of oxygen and hydrogen. The colouring matter of linen, then, is composed principally of carbon and hydrogen.

Oxygen combines with hydrogen at a lower temperature than it does with carbon; for if a confiderable quantity of oxy muriatic acid be mixed with a folution of fugar (a fubitance which confifts chiefly of carbon and hydrogen), and the liquor be evaporated, there remains behind little else than carbon, the hydrogen having combined with oxygen and formed water, which had passed off in the form of vapour. Now, whenever a quantity of hydrogen is separated from a body principally composed of hydrogen and carbon, that body assumes a brown or yellow colour, because the carbon becomes predominant; and this colour becomes the deeper the greater the proportion of the carbon is, compared to that of the hydrogen; and at last, when nothing but carbon remains, it becomes quite black.

It is probable, then, that when the oxy-muriatic acid renders linen white a quantity of oxygen has combined with the colouring particles, but that this oxygen gradually enters into a combination with the hydrogen, and forms water which paffes off; that then the carbon becomes predominant, and the linen in confequence affumes a yellow colour*.

The fame method does not fucceed in bleaching wool and filk which answers for linen and cotton. One

would be disposed to think that these substances are Bleaching. bleached rather by losing oxygen than by absorbing it.

Wool, for instance, is rendered white very quickly when Bleaching exposed to the sumes of sulphurous acid, which we of wool and know has a strong affinity for oxygen, and soon satussilk. rates itself with it. But what passes during the whitening of animal matters has never yet been properly enquired into, though it would not only greatly elneidate bleaching, but dyeing likewise, and throw much light upon some of the obscurest parts of chemistry. A great improvement, however, has lately been made by M. Baumé in the manner of bleaching filk. Of this improvement we shall proceed to give an account †.

Before the filk is wound off the cocons in which the the Ann. do filk worms are inclosed, it is necessary to kill the in-Chym. xvii. feets, otherwise they would in all probability eat thro' 156. and as it and destroy it. This is commonly done by exposing bridged in the cocons, properly wrapped up, for two hours to the Journal, 1. heat of about 158 degrees of Fahrenheit in an oven.; 2. from after which they are kept for a certain time in a mais which last to preferve their heat, and effectually deflroy fuch of we have ta-the infects as might have escaped the power of the count of it. oven. The effect of this process is, that the filk is hardened, and is more difficult to wind off than before. New mode Hence the product of filk is lefs by one ninth part in of whitenquantity, and inferior in quality to what might have ing filk. been obtained by winding off without this previous baking. Mr Baumé, not only from these views, but likewife because the filk which has not been baked proves fusceptible of a greater lustre, was induced to destroy the cryfalis by spirit of wine. For this purpose he disposes them in a wooden box in a stratum fix inches deep: upon each square foot half a pint of spirit of wine is to be sprinkled with a small watering pot made for that purpose. The liquid is to be equally distributed, but it is not necessary that all the cocons should be wetted. They are then to be mixed by hand. In the next place another fratum is to be formed over the first, nearly of the same depth, which is to be sprinkled and treated as before. By this method of proceeding. the box becomes filled, and must then be covered, and left for 24 hours, during which time they become spontaneously heated to about 100 degrees, and the vapour of the spirit of wine exerts itself with wonderful activity. After this treatment they must be spread out to dry, which happens in a short time, and is absolutely neceffary previous to winding off.

The spirit of wine to be used in this operation ought to be of the specific gravity .847, at the temperature of 55 degrees. It is of the greatest importance to use that spirit only which has been kept in vessels of glass, of timed copper, or of pure tin. Leaden vessels are absolutely to be rejected; wooden vessels tinge the spirit, which gives the silk a degree of colour of considerable permanency, and very inimical to the bleaching process.

The filk is wound off upon a reel, while the cocons are kept immerfed in water almost boiling. Upon this part of the process M. Baumé remarks, 1st, That the dead cocons must be separated. These are known by the brown or black spots on their surface. 2. That well water, which on account of its clearness is almost universally used in the filk manufactories, mostly contains nitre, and is extremely prejudicial to the bleaching process. The presence of nitrous acid gives a yellow colour, which resists bleaching and even scouring; he

therefore.

0

Ann. de ym. VI. any other faline substance is of the least advantage to the colour, beauty, or quality of the filk.

At the four places of contact of the filk upon the reel, all the threads flick together. It is absolutely neceffary that this should be remedicd. The method confifts in foaking the filk in a fufficient quantity of warm water, at about 90 degrees, for about two hours; after which the threads are to be separated by opening the hanks upon a pin, and lightly rubbing the parts which

cohere. When the filk is dry, it is to be loofely folded in its original form, and is ready for bleaching.

The filk while wet is foft, and part of its gummy matter is in fuch a state, that its threads would readily adhere, if wrung while warm for the purpose of clearing it of the water. After fuch improper treatment there would be no other remedy than to foak it again in warm

The apparatus for bleaching the filk confifts of a stone-ware vessel, nearly of a conical form, capable of holding about 12 gallons, having a large opening at the one end, and a smaller of about an inch diameter at the other end. Common pottery cannot be used in this operation, because it is soon rendered unserviceable by the action of the muriatic acid, and the stone-ware itself is not very durable. This vessel must be carefully examined, to ascertain that it does not leak in the slightest degree; after which the infide is to be rubbed with a pumice-stone, to clear it of asperities which might break the threads. A cover of the same material is to be fitted on by grinding; and the smaller aperture, which in the use is the lowest, is to be closed with a good cork, in the middle of which is thrust a small glass tube about a quarter of an inch in diameter; this is likewise stopped with a cork, excepting at the time when it is required to draw off the liquid contents of the jar. A small perforated false bottom is placed within the vessel, to prevent this tube from being obstructed.

Six pounds of yellow raw filk are to be disposed in the earthen pot; upon this is to be poured a mixture, previously made, of 48 pounds of spirit of wine of the specific gravity .867, with 12 ounces of very pure marine acid, absolutely exempt from all presence of nitrous acid, and of the specific gravity 1.114. 'The pot is then to be covered, and the whole left in digestion till the following day, or until the liquor, which at first afsumes a fine green colour, shall begin to assume that of

a dufky brown.

The acidulated spirit is then to be drawn off, clean spirit of wine poured upon the filk, and drawn off repeatedly until it passes colourless. The filk is then furfered to drain without stirring it. In this state it is

ready for a second infusion.

Forty-eight pounds of spirit of wine, acidulated with 12 ounces of marine acid, is now to be poured on the filk, and the whole fuffered to remain for 24 hours or longer, until the filk becomes perfectly white. The time required for this fecond infusion is commonly longer than for the first: it fometimes amounts to two, three, or even fix days, according to circumstances, particularly the temperature and the nature of the filk. Silk which has been in the oven is in general more dif-

When the filk has thus obtained its utmost degree of

Bleaching, therefore recommends river-water.

3. In some countries a small quantity of alum is used. Neither this nor separate vessel. This shuid is but slightly coloured, and may be used again in the first insusion of other yellow filk, with the addition of fix ounces more of marine acid. The receiving vessel is to be removed, and another clean veffel substituted in its place. The filk is then fprinkled with clean spirit, and occasionally pressed down with the hand. As foon as the spirit of wine comes off absolutely colourless, a third infusion is to be made by pouring upon the filk 48 pounds of the pure spirit without acid, which is to remain till the following day: it is then to be drawn off, and reserved for washing other filk after the first infusion.

After the filk has been left to drain, and affords no more spirit, it still retains its own weight of that fluid. This is recovered by fprinkling the filk with a small quantity of very clear river-water at a time. While the water applies itself and subsides along the filk, it drives the spirit of wine before it, so that the first portions which flow from the tube are fcarcely diminished in strength. The addition of water is to be continued until nothing but mere water comes off below.

In this fituation the filk is found to be well bleached, but fill retains a portion of marine acid fufficient to render it harsh to the touch, and after a time brittle. It must be washed off with water. The best method is to put the filk loofely into a coarfe woollen bag, which is to be fecured loofely in another cloth like a small bed or pillow, then placed in a basket, and left in a running stream for five or fix hours; but where the convenience of a fiream is wanting, the earthen pot containing the filk is to be covered with a cloth, and water pumped through it for five or fix hours, or until that which iffues from the lower aperture gives no red colour to the tincture of turnfol. At this period the lower opening is to be closed, and the veffel filled with water, which must be changed once or twice in 24 hours.

Though the mineral acids are the most powerful and destructive of all faline substances, yet they may be applied to filk when diluted with spirit of wine in very confiderable doses. In trials made to ascertain the maximum, two ounces of marine acid were added to one pound of spirit of wine, without altering the filk. Two drams of marine acid cause a very perceptible alteration

in one pound of filk.

Spirit of wine which has been mixed with nitrous acid cannot be used in bleaching, even though afterwards rectified upon an alkali, because it still retains a portion of nitrous gas. Pure fpirit of wine without acid extracts a fine yellow colour from filk, which does not separate for years, even though exposed to the fun's light. Yellow filk, exposed to the fun, loses its colour in a short time. The acidulated spirit which has been used in the infusion of filk, is changed by exposure to the fun, but not in fuch a manner as to be rendered fit for use a second time. In order to obtain a beautiful white colour, it is effential that the filk should be immerfed in a large quantity of the fluid, especially at the first infusion. Without this management it would become necessary to make three infutions in the acidulated spirit. When the first infusion is well managed, the filk will have loft all its yellow colour, and become confiderably white, at the same time that the liquor will have begun to change colour a little. As long as it continues of a fine green, it is certain that it has not

exhaufted

eaching exhaufted its whole action upon the filk. The duration acid, and loaded with colouring matter. In this flate Bleaching. of this first infusion may be longer or shorter, without inconvenience, according to the temperature. When the temperature is at 77 of Fahrenheit, the first infufion is often made in 10 or 12 hours. In small experiments the heat of the atmosphere may be supplied by the water bath; in which case, all the insusions are eafily made in the course of a day.

When the first infusion is finished, and the liquor drawn off, the filk appears greenish: the subsequent washings in spirit of wine clear it of the liquor it retained. This sprinkling should be made with the watering pot, otherwise the quantity poured will be great-

er, and the management more waiteful.

Pieces of gauze and entire garments of filk have been

fuccefsfully bleached in this way.

The finest natural white filks are rendered infinitely whiter by this process. Spirit of wine alone has the property of depriving yellow filk of its colour, which it brings to the state of the naturally white filk. In this flate the filk is disposed to acquire a greater degree of brightness by a fingle infusion in the acidulated spirit. This process has its advantages over the other, to which it is also inferior in certain respects; concerning neither of which the author has entered into any detail.

The colouring matter was found to be a refin perfeely animalized, affording by diffillation the fame products as other animal matters, and the concrete volatile

alkali.

Silk whitened by fcouring may be dried freely in the air without affecting its lultre. This is not the cafe with the filk bleached in the gum: if it be left at liberty to dry in the air, it refembles white flax without any luftre. The beauty of this filk confifts in its shining brilliancy; to secure which it must be dried in a state of tension. Mr Baumé has contrived a simple machine for this purpole. It confifts of a strong square frame of wood standing upright upon feet: the upper horizontal bar is fix feet long, and has fix iron pins driven through it at equal distances, so as to project on each fide for the purpose of receiving twelve bobbins. The lower horizontal bar is moveable up and down in a mortice, by means of a screw at each end: it is furnished with fix holes, adapted to receive as many pins to correspond with those above. The skains of filk are to be dreffed and arranged upon wooden pins, as they are taken out of the lack from washing. As soon as there are twelve together, they are to be wrung with a staff; after which the skains are to be hung one by one upon as many bobbins put upon the upper pins of the square frame. Another bobbin with tails is to be inferted in the lower loop of the skain, and fastened to the correfponding pin of the lower bar, by means of a strap and hook, which need not be described to such as are slightly acquainted with mechanical objects. When the machine is thus supplied with skains on both sides, the lower bar of the frame is to be pressed down by the screws until the filk is moderately stretched. When it is dry, the screws are to be equally flackened, the skains taken off, and folded with a flight twift, that they may not become entangled.

To complete the description of this process, it only remains to show how to recover the alcohol, and ensure the purity of the acids made use of.

it cannot be again used. There are two methods of diffilling it, which have their respective advantages and Method of inconveniences.

By the first the acid is lost; which is faturated with the alcohol potais, in order that the diffillation may be afterwards used, performed in a copper alembic. A folution of potals is to be poured into the acid spirit, and stirred about to promote the faturation. Carbonic acid is difengaged with strong effervescence from the alkali, and the point of faturation is known by the ufual test, that the sluid does not redden the tincture of turnfol. The diffillation is then to be made in the copper alembic, and the

alcohol referved in proper veffels.

In the fecond process for distilling without alkali, the acid spirit is distributed into a great number of glass retorts, placed in the fand-bath, on the gallery of a furnace. The first product is scarcely acid; but what follows is more and more fo, and must be kept in vesfels of glass or stone-ware, which become embarrassing on account of their number. The fluid which remains in the retorts has the colour of beer flightly turbid, and contains the greatest part of the marine acid. It must be poured into one or more retorts, and concentrated by heat gradually applied. The first liquor which comes over is flightly red, turbid, and fcarcely acid. This is to be thrown away, and the receivers changed. The fucceeding product is the colourless marine acid, of an aromatic smell resembling the buds of poplar. The refin of the filk remains in the retort decomposed by the The marine acid thus obtained is weaker than it originally was; which is in fact of little confequence, as it is pure, and may be fafely used, either by increafing the dose proportional to its diminished strength, or by concentrating it if required in the usual way. If this diffillation be made in a filver alembic, instead of retorts of glafs, and a capital and worm of pure tin be annexed, the alcohol will be obtained fo flightly acid as fcarcely to redden the tincture of turnfol; but it is fufficiently acid to receive injury if preferved in a cop-

As to the acid, Mr Baumé observes, that the muria- And of pretic acid of commerce is unfit for the purpose. It was paring a formerly prepared with the marine falt of the faltpetre pure mumanufacturers; and even when it is made with good falt, the decomposition is effected with common vitriolie acid which contains nitrous acid. Marine acid mixed with a fmall quantity of nitrous acid does not prevent the filk from being beautifully whitened: it even accelerates the process considerably, and in the most fatisfactory manner. But the alcohol, every time it is used and rectified, becomes charged with the acid and gas of nitre, which affume the characters of the nitrous anodyne liquor. In this flate neither distillations nor repeated rectifications from alkali are fufficient to feparate the nitrous matter from the alcohol. Then it is that the fuccess of the operator vanishes, with a degree of rapidity equal to the advances which encouraged his

hopes at the commencement.

To purify common sulphuric acid, 100 pounds of it are to be mixed in a large bason of copper with the same quantity of river-water, and stirred with a wooden spatula. The mixture instantly becomes heated to the boiling water point, and a great quantity of red vapour The alcohol which has been used in bleaching filk is is disengaged, which has the smell of aqua-regia, and

Bleaching

paper.

mixture is made, it is proper to immerfe the bason to a the acid with which the book is impregnated, and cooling. As foon as it is sufficiently cooled, it is to be tracted. drawn off into bottles, and left to become clear during feveral days. It is in the next place to be decanted, and conveyed into retorts by a fyphon funnel, and the rectification proceeded upon until it becomes perfectly white. Towards the end of the operation a small quantity of fulphur fublimes in the neck of the retort. Inflead of receivers, a finall glass cup is placed beneath the aperture of each retort, in order to facilitate the diffipation of the nitric and muriatic acids. When the acid in the retorts is fufficiently cooled, it is poured a fecond time into the copper bason, and mixed with 100 pounds of river-water, as at first, and again concentrated in the retorts till it becomes perfectly clear. The muriatic acid is to be difengaged from common falt by the application of this acid in the usual manner.

The oxy-muriatic acid is also used very generally for bleaching paper, or rather the fluff out of which paper is made. It has been alleged, and we believe with some truth, that fince this mode of whitening paper was introduced into this country, the strength of paper is much inferior to what it was formerly. If this be really the case, perhaps it is owing to the use of too

concentrated an acid.

We shall finish this article with Mr Chaptal's account of this process, who was the first person that introduced it. "Blotting paper (fays he), by being put into oxygenated muriatic acid, is bleached without fuffering any injury; and rags of coarse bad cloth, such as are used in the paper manufactories to make this kind of paper, may be bleached by this acid, and will then furnish paper of a very superior quality. I bleached by it an hundred weight of paste, intended to be made into blotting paper, and the increase of value in the product was computed at 25 per cent. whereas the expence of the operation, when calculated in the ftrictest manner, amounted only to 7 per cent.

Mode of whitening

old books,

"The property possessed by this acid, of bleaching paper without injuring its texture, renders it very valuable for restoring old books and smoked prints. The latter, when discoloured to such a degree that the subject of them could hardly be diffinguished, were re-eftablished and revived, in so astonishing a manner that they appeared to be new; and old books, foiled by that yellow tinge which time always produces, may be fo completely renewed, that one might suppose them to be just come out of the press. The simple immersion of a print in oxygenated muriatic acid (leaving it therein a longer or a shorter time, according to the strength of the liquor) is all that is required for bleaching it; but when a book is to be bleached, some farther precautions are to be used. As it is necessary that the acid should wet every one of the leaves, the book must be completely spread open, and then, by letting the boards of the binding rest upon the fides of the vessel, the paper only will be immerfed in the liquor. If any of the leaves flick together, they must be carefully separated, that all of them may be equally impregnated. The liquor takes a yellow tinge, the paper grows white; and after two or three hours the book may be taken out of the liquor, and foaked in clean water, which should

Bleaching, arises from the nitric and muriatic acids. When this be changed from time to time, in order to wash out Bleaching fuitable depth in a large veffel of water, to haften the also to deprive it of the disagreeable smell it has con-

> "The above method, which is the first I made use of, has generally succeeded pretty well; too often, however, the leaves of my books have had a motley appearance, and fometimes feveral pages were not at all bleached; I was therefore obliged to have recourse to the following more certain process. I began by unlewing the books, and reducing them into sheets; these sheets I placed in divisions made in a leaden vessel, by means of thin flips of wood, fo that the leaves when laid flat were separated from each other by very small intervals. I then put the acid into the veffel, pouring it against the side, that the leaves might not be disturbed; and when the operation was finished, I drew off the acid, by means of a cock fixed in the bottom of the veffel. I then filled the veffel with clean water, which washed the leaves, and took off the smcll of the oxygenated acid. They may then be dried, finoothed, and new bound. In this manner I have restored many valuable books, which had become worthless from the bad flate they were in.

"When I had to bleach prints fo torn to pieces And prints that they confifted only of fragments fitted together, and pasted upon paper, I was afraid I might lose some of these fragments in the liquor, because they separate from the paper by the foftening of the paste; in that case therefore I took the precaution of enclosing the print in a large cylindrical bottle, which I turned upfidedown, fixing its mouth to that of a veffel in which I had put a mixture proper for difengaging oxygenated muriatic gas. This gas fills the infide of the bottle, and, acting upon the print, takes off the flains, ink-fpots, &c. while the fragments remain pasted to the paper, and confequently keep their respective places."

CAPE OF LARGE SNOUTED BOAR, a species of the genus Sus, which, according to M. Vaillant, differs from every known species, and has not been accurately described by any writer of natural history. Buffon, indeed, in the Supplement to his History of Quadrupeds, has given a figure of it; but nothing like the head of the animal is discoverable, says our author, in that sigure, all its characteristics having been omitted by the draughtsman. M. Vaillant, during his last travels in Africa, thot a monttrous boar of this species on the banks of Fish-river, and in the country of the Greater NIMIQUAS. He describes it in the following terms: Its fnout, instead of being taper and in the form of a Plate VIII probofcis, is, on the contrary, very broad and fquare at the end. It has fmall eyes, at a very little distance from each other, level with the furface, and near the top of the forehead. On each cheek a very thick cartilaginous skin projects horizontally, being about three

inches long and as many broad. At first fight you land, Germany, and Denmark, which Dr Bonet ar- Bonnet, would be tempted to take these excrescences for the ears; particularly as the real ears of the animal, flicking as it were to the neck, which is very short, are partly concealed by an enormous mane, the briftles of which, in colour red, brown, and greyish, are 16 inches in length on the shoulders. Directly below these false ears is a bony protuberance on each fide, projecting more than an inch, ferving the animal to frike with to the right and left. The boar has, besides, four tusks, of the nature of ivory. two in each jaw: the upper ones are seven or eight inches long; very thick at the base, and terminating in an obtuse point, grooved, and rising perpendicularly as they issue from the lips: the lower ones are much smaller, and so close to the upper ones when the mouth is shut, that they appear as one. The head is a truly hideous object. It is scarcely less so than that of the hippopotamus, to which at first view it appears to have a striking resemblance. Systematists, accustomed to view nature only according to rules established by themselves, will be far from acknowledging this animal to be a boar; for, not to mention its large fnout, it wants incifive teeth in both jaws. Notwithflanding its wide muzzle, it ploughs up the earth to feek for roots, on which it feeds. It is very active, though large and bulky; running with fuch speed, that the Hottentots give it the name of the runner.

BONET (Theophilus), was born at Geneva in the year 1620. His parents were able to give him the most liberal education, and his genius directed him to the fludy of physic; and that he might have every advantage, he attended on the lectures of the most eminent professors in many of the celebrated universities in Europe. In 1643 he was admitted to the degree of M D. and was for some time physician to the Duke of Longueville. His superior skill in his profession soon brought him into confiderable repute; but being feized with an excessive deafness, he was obliged to retire from busi-

ness when about 60 years of age.

During this retirement he employed himself in collecting all the observations which he had made in a practice of forty years duration, and in arranging them under proper heads. His first publication, which was intitled Pharos Medicorum, &c. confifts of practical cautions, extracted mostly from the works of Bellonius; and in it he points out many errors which then prevailed in the general practice of physic. Of this work he gave to the world a fecond edition, confiderably improved and greatly enlarged; and in 1687 it was a third time printed at Geneva, under the title of Labyrinthi medici extricati, &c.

In 1675 he published Prodromus anatomia practice, sive de abditis morborum causis, &c. This was intended merely as an introduction to a work that foon followed, under the title of Sépulchretum, sive anatomia pradica ex cadaveribus morbo denatis. In these two publications he has collected a great number of curious observations upon the difeases of the head, breaft, belly, and other

parts of the body.

In 1682 appeared at Geneva Mercurius Compitalius, sive index medico-practicus per decisiones, cautiones, &c. in folio; and in 1684 and 1686 two volumes in folio likewise, intitled Medicini Septentrionalis collatitia. This last work is a collection of the best and most remarkable observations in physic which had been then made in Eng-

SUPPL. VOL. I. Part I.

ranged under proper heads, according to the feveral parts of the human body. At Geneva, in 1692, was published, in three volumes folio, Polyalthes, five Thesaurus medica practicus ex quibuslibet rei medica scriptoribus congestus, &c. and some years before, he gave to the world correct editions of Theodori Turqueti de Maerne tractatus de arthritide, una cum ejusdam aliquot consiliis; and of Jacobi Rohaulti tractatus physicus e Gallico in I.atinum versus. This laborious and useful author died of a dropfy on the 29th of March 1698.

BONNET (Charles), was descended from a French family, who being compelled, on account of their religious principles, to emigrate from their native country, established themselves at Geneva in the year 1572. His grandfather was advanced to the magistracy in that city, and adorned by his integrity an eminent station. His father, who preferred the flation of a private citizen, paid unremitted attention to the education of his fon, who was born on the 13th of March 1720; and Charles, at a very early period, recompensed his father's affiduity, by the amiableness of his disposition, and the rapid progress he made in general literature. When he was about 16 years of age, he applied himself, with great eagerness, to the perusal of Le Spectacle de la Nature; and this work made fuch a deep impression on his mind, that it may be faid to have directed the tatte and the studies of his future life. What that publication had commenced, was confirmed by the work of La Pluche; but having accidentally feen the treatife of Reaumur upon infects, he was in a transport of joy. He was very impatient to procure the book; but as the only copy in Geneva belonged to a public library, and as the librarian was reluctant to entrust it in the hands of a youth, it was with the utmost difficulty that he could obtain his end.

By the possession of this treasure, our assiduous youth was enabled to make feveral new and curious experiments, which he communicated to Reaumur himself; and the high applause he gained from so great a natu-

ralist added fresh vigour to his affiduity.

In compliance with his father's defires, he applied himself, though with much reluctance, to the study of the law. The works of Burlamaqui pleased him the most, on account of the perspicuous and philosophic manner in which the subject was treated: the institutes of Heineccius gave him some courage also, as he perceived order and connection; but the Roman law terrified him as the hydra of Lerna. Notwithstanding his application to these authors, he fill continued attached to natural history, and was very active in making experiments. The experiments which demonstrate that treelice propagate without copulation, was communicated by Reaumur to the Academy of Sciences; and this circumstance occasioned an epistolary correspondence between M. Bonnet and that great naturalist. This was doubtless very flattering to a youth of twenty years. The letter of Reaumur was accompanied with a prefent of that very book which he had borrowed with fo much difficulty two years before.

Animated by fuch distinguished marks of approbation, he diligently employed every moment he could steal from the study of jurisprudence to the completion of his natural history of the tree-louse; to experiments on the respiration of catterpillars and butterflies, which

Bonnet. he discovered to be effected by stigmata, or lateral porce; to an examination of the construction of the tænia or tape-worm; in frequent correspondence with Reaumur; and in afifting Trembley in his discoveries and publication concerning millepedes, &c. Having in the year 1713 obtained the degree of doctor of laws, he relinquished a pursuit which he had commenced with fo much reluctance. In the same year he was admitted a fellow of the Royal Society, to which he had communicated a treatife on infects.

Bonnet being now liberated from his other pursuits, applied himself, without intermission, to collecting together his experiments and observations concerning the tree loufe and the worm, which he published in 1744 under the title of Infectology. This work acquired deferved approbation from the public, and was honoured by the commendation of the celebrated B. de Justieu. He was reproached, however, in a periodical publication, with having paid too little attention to the delicacy of his reader; though his patience and accuracy were acknowledged to be deferving of praise. Such unremitted application and labour could not fail of becoming injurious to his health. Inflammations, nervous fever, fore eyes, &c compelled him to relinquish the use of the microscope and the study of insects. This prevention was so extremely mortifying to a man of his tafte and activity of mind, that he was thrown into a deep melancholy, which could only be fubdued by the resolution inspired by philosophy, and the consolations of religion: these gradually roused him from a dejected flate of mind. About the end of the year 1746 our philosopher was chosen member of the Literary Institution at Bologna, which introduced him to a correspondence with the famed Zanotti, who may be deemed the Fontenelle of Italy.

In the year 1747 he undertook a very difficult work on the leaves of plants; which, of all his publications in natural history, bore the strongest marks of originality, both with respect to the manner in which his experiments were made, and the discoveries resulting from them. His extreme attachment to natural history gradually led him to a study of a very different nature; speculative philosophy now engaged his whole attention. The first truits of his meditations in this department was his Effay on Pfychology. In this work the principal facts observable in human nature, and the consequences resulting from them, are stated in a concise and conspicuous manner. He contemplated man from the first moment of his existence, and pursued the developement of his fenses and faculties from simple growth up to intelligence. The work, which was published without his name, met with great opposition, and was criticifed with feverity; but the censures were directed more against his expressions than his principles; nor were they of sufficient importance to impede the general acceptance of the publication.

His analysis of the mental faculties was simply a developement of the ideas contained in the preceding work. It engaged his inceffant attention for the space of five years; nor was it completed before 1759. It is somewhat singular that both he and the Abbé de Condillac should have illustrated their principles by the supposition of a statue, organized like the human body,

they carefully traced. In the year 1760 this work was Bonnes published at Copenhagen, by order and at the expence of Frederick V. and it was followed in 1762 by contemplations on organized bodies. In this the author had three principal objects before him; the first was to give a concile view of every thing which appears interefting in natural history, respecting the origin, developement, and reproduction of organized bodies; the fecond was to confute the two different systems founded upon the Epigenesis; and the third was to explain the fystem of Germs, indicate the ground upon which it was founded, its correspondence with facts, and the consequences resulting from it. This work was received with much fatisfaction by natural philosophers. The Academy o' Berlin, which had proposed the same subject as a prize question for 1761, declared that they confidered the treatife as the offspring of close observation and profound reasoning; and that the author would have had an indubitable right to the prize, if he had confined his labours to the precise flatement of the question. It must also be recorded, to the honour of the great Malesberbes, that he reversed the interdict which the public -cenfor had laid upon this book, under the pretext that it contained dangerous principles.

The Contemplation of Nature appeared in 1764. In this work the author first enlarged upon the common conceptions entertained concerning the existence and perfections of God; and of the order and uniformity observable in the universe. He next descends to man, examines the parts of his composition, and the various capacities with which he is endowed He next proceeds to the plants; assembles and describes the laws of their economy; and, finally, he examines the infects, indicates the principal circumstances in which they differ from larger animals, and points out the philosophical inferences that may legitimately be deduced from these differences; and he concludes with observations respecting the industry of infects. This work being of a popular nature, the author spared no pains in bestowing upon it those ornaments of which it was susceptible. The principles which he thus discovered and explained, induced him to plan a fyslem of moral philofophy; which, according to his ideas, confifted folely in the observance of that relation in which man is placed, respecting all the beings that surround him. The first branch would have comprehended, various means which philosophy and the medical science have discovered for the prevention of disease, the preservation and augmentation of the corporeal powers, and the better exertion of their force: in the second, he proposed to shew, that natural philosophy has a powerful tendency to embellish and improve our mind, and augment the number of our rational amusements, while it is replete with beneficial effects respecting the society at large. To manifest the invalidity of opinions, merely hypothetical, he undertook, in the third place, to examine, whether there were not truths within the compals of human knowledge, to which the most sceptical philosopher must be compelled to yield his confent, and which might ferve as the basis of all our reasonings concerning man and his various relations. He then would have directed his attention to a first cause, and have manifested how greatly the idea of a Deity and Supreme Lawwhich they conceived to be gradually infpired with a giver favoured the conclusions which reason had drawn foul, and the progressive developement of whose powers from the nature and properties of things: but it is

deeply to be regretted that his health, impaired by incessant labour, would not permit him to complete the

His last publication was the Palingenesis, which treats of the prior existence and future state of living beings.

Of his publications in natural history, those deemed the most excellent are, his Treatise on the best Means of preserving Insects and Fish in Cabinets of Natural History; a Differtation on the Loves of the Plants; fundry vieces on the Experiments of Spallanzani, con. cerning the Reproduction of the Head of the Snail: a Differtation on the Pipa, or Surinam Tod; and different Treatises on Bees.

In the year 1783 he was elected honorary member of the Academy of Sciences at Paris; and of the Academy of Sciences and the Belles Lettres at Berlin.

Much of his time was employed in a very extensive correspondence with some of the most celebrated natural philosophers and others. Of this number were Reaumur, De Geer the Reaumur of Sweden, Du Hamel, the learned Haller, the experimental philosopher Spallanzani, Van Swieten, Merian, and that ornament of Swiczerland the great Lambert. I-Ie entertained, however, the atmost aversion to controversy. He thought that no advantage to be obtained by it could compenfate for the loss of that repose which he valued, with Newton, as the rem prorsus substantialem. He never answered remarks that were made to the prejudice of his writings, but left the decision with the public; yet, ever ready to acknowledge his errors, he was fincerely thankful to every one who contributed to the perfection of his works. He was used to say, that one confession, I was in the wrong, is of more value than a thousand ingenious confutations.

His literary occupations, and the care he was obliged to take of his health, prevented him from travelling. He delighted in retirement, and every hour was occupied in the improvement of his mind. The last 25 years of his life were spent in the same rural situation where he had passed the greater part of his early days; yet notwithstanding the pursuit of literature was his supreme delight, he never refused to suspend his studies, when the good of his country feemed to demand his

fervices.

He was chosen in 1752 member of the Grand Council in the republic of Geneva; and he affifted regularly at their deliberations till the year 1768, where he distinguished himself by his eloquence; his moderation, united with firmpess; by his good sense and penetra-tion in cases of difficulty; and by the zeal with which he endeavoured to reclaim his fellow-citizens to that ancient simplicity of manners which had been so conducive to the welfare of the state, and to the love of virtue, so effential to the existence of genuine liberty. His conduct, in every case, was consistent with his principles. He took no pains to accumulate wealth, but remained fatisfied with a fortune equal to his moderate wants, and to the exercise of his benevolence. The perfect correspondence between his extensive knowledge and virtuous deeds procured him universal esteem.

In the year 1788 evident symptoms of an hydrops pelloris manifested themselves; and from this time he gradually declined. He sustained his indisposition with unremitted cheerfulness and composure. After various

20th of May 1793, in the 73d year of his age; retain- Booking his presence of mind to the last moment, administer- keeping. ing comfort to furrounding friends and relatives, and attempting to alleviate the distress of his disconsolate wife, in whose arms he expired.

As a demonstration of the high value placed upon his labours and talents by the literati, we have only to remark, that he was member of most of the learned fo-

cieties of Europe.

BOOK KEEPING, is an art of which the importance is univertally known; and as commonly practifed, it has been sufficiently explained in the Encyclopædia Britannica. But fince that article was written, a great improvement has been introduced into the art, or rather a new method of book-keeping has been invented, by Mr Edward Thomas Jones, of the city of Briffol, accountant, who calls it the English system of book-keeping; and thinks that by it accounts may be more regularly kept, and errors in accounts more eafily detected, than by any other method hitherto known. We are much inclined to be of his opinion; and shall therefore lay before our readers his description of this method, as we find it in the specification of the patent which was

granted to him January 26. 1796.

The English System of Book-Keeping requires three books, called a day-book or journal, an alphabet, and a ledger, which must be ruled after the following method, viz. the day-book to have three columns on each page, for receiving the amount of the transactions; one column of which to receive the amount of debits and credits, one column to receive the debits only, and one column to receive the credits only; or it may be ruled with only two columns on each page, one column to receive the amount of the debits, and one column to receive the amount of the credits. There must also be on each page of the day-book four other colums ruled, two on the left fide next the amount of the debits, and two on the right fide next the amount of the credits, for receiving the letter or mark of poning, and the page of the ledger to which each amount is to be posted.

The alphabet need not be ruled at all, but must contain the name of every account in the ledger, the letter that is annexed to it as a mark of posting, and the page

of the ledger.

The ledger must be ruled with three, four, five, or feven columns on each page, as may be most agreeable, for receiving the amounts of the different transactions entered in the day book. And the process for using these books, or making up books of accounts on this plan, is as tollows.

When a person enters into trade, whether by himself or with copartners, he must have an account opened with himself in the ledger; entering first in the daybook, and then to the credit of his account in the ledger, the amount of the property he advances into trade: The account may be headed either with his name only, or else called his stock account.

If you buy goods, give the person credit of whom you purchase; when you sell goods, debit the person to whom faid goods are fold. If you pay money, debit the person to whom paid, not only for what you pay, but also for any discount or abatement he may allow, and give the cashier credit for the neat amount paid. If you receive money, credit the person of whom you fluctuations, usual in that complaint, he died on the receive it, not only for what he pays, but also for any

cashier for the neat amount received; taking care in merely a plain narrative of the fact, introducing not one useless word, and avoiding every technical term or phrase except the words debit and credit, which are full and comprehensive, and the only terms that are applicable to every transaction, and may be affixed to every entry.

But as a hurry of business will sometimes take place in almost every counting house, which may cause the entries to be made to the debit instead of the credit of an account in the day book, and to the credit instead of the debit, Mr Jones has endeavoured as much as possible to counteract the evil, by having only one column for receiving the amount of every transaction, whether debits or credits, at the instant of making the entry; and, for the convenience of feparating the debits from the credits, previous to posting, which is necessary to prevent confusion and perplexity, he has two other columns on the same page; that on the left fide into which the amount of every debit must be carefully entered, and that on the right for the amount of the credits, which columns must be cast up once a month. The column of debits and credits of itself forming one amount; the column for the debits producing a fecond amount; and the column of credits a third amount; which fecond and third amounts, added together, must exactly agree with the first amount, or the work is not done right.

By this means the man of bufiness may obtain monthly fuch a flatement of his affairs as will show how much he owes for that month, and how much is owing to him; and the debits being added together for any given time, with the value of the flock of goods on hand, will, when the amount of the credit is fubtracted there-

from, shew the profits of the trade.

Our author now proceeds to the process of posting; which begins with opening an account in the ledger with every person to whose debit or credit there has been an entry made in the day-book; affixing to each account a letter, which is to be nfed as a mark of posting. The person's name, place of abode, and the folio of the ledger, must then be entered in the alphabet, with the same letter prefixed to each name as is affixed to the account in the ledger. Next the page of the ledger on which each account is opened (and which will be seen in the alphabet) must be affixed to each amount in the day-book, in the column for that purpose. date and amount of each debit must then be posted in the columns for receiving it in the ledger, on the left or debit fide of that account to which it relates; entering, as a mark of posting in the day-book, against each amount, the same letter that is affixed to the account in the ledger, to which faid amount may be posted. Obferving that the debits of January, February, March, &c. must be posted into the column for those months in the ledger, and the credits must also be posted in like manner, filling up each account in the centre, at the expiration of every month, with the whole amount of the month's transactions; thus having, in a imall space, the whole statement of each person's account for the year; in the colums to the right and left the amount separately of each transaction; and in the centre a monthly statement.

Having described the process of this method of book-Lecping, he thus shews how to examine books kept by

discount or abatement you may allow, and debit the this method, so as to ascertain, to an absolute certainty, if the ledger be a true reprefentation of the day book; Recting, Bostovich these entries to have nothing mysterious or obscure, but i. e. not only if each transaction be correctly posted, as to the amount thereof, but also if it be rightly entered to the debit or credit of its proper account. This examination differs from the modes that have heretofore been practifed, as well in expedition as in the certain accuracy which attends the process; it being only neceffary to cast up the columns through the ledger debits and credits, according to the examples given; and the amount of those columns, if right, must agree with the columns in the day book for the same corresponding space of time. These castings should take place once a month; and if the amounts do not agree, the posting must then, but not else, be called over; and when the time, whether it be one, two, three, or four months, that is allotted to each column of the ledger is expired, the amount of each column should be put at the bottom of the first page, and carried forward to the bottom of the next, and so on to the end of the accounts; taking care that the amount in the day-book, of each month's transactions, be brought into one gross amount for the same time.

But although this process must prove that the ledger contains the whole contents of the day-book, and neither more nor less, yet it is not complete without the mode of ascertaining if each entry be posted to its right account; which may be afcertained by the following method. He has laid down a rule that a letter, which may be used alphabetically in any form or shape that is agreeable, shall be affixed to each account in the ledger, and the fame letter prefixed to the names in the alphabet, these letters being uted as marks of posting, and affixed to each account in the day-book as it is posted; it is only necessary therefore to compare and see that the letter affixed to each entry in the day book is the fame as is prefixed to the fame name in the alphabet; a difference here shews of course an error, or else it

mult be right.

At the end of the year, or at any other time, when persons balance their accounts, if there be no objections to the profits of the trade appearing in the books, the flock of goods on hand at prime cost may be entered in the day-book, either the value in one amount, or the particulars specified, as may be most expedient, and an account opened for it in the ledger, to the debit of which it must be posted. The casting up of the ledger must then be completed; and when found to agree with the day book, and the amount placed at the bottom of each column, fubtract the credits from the debits, and it will shew the profit of the trade; unless the credits be the greater amount, which will fhew a loss. In taking off the balances of the ledger, one rule must be observed, and it cannot be done wrong: As you proceed, first iee the difference between the whole amounts of the credits and debits on each page for the year, with which the difference of the ontitanding balances of the feveral accounts on each page must exactly agree, or the balances will not be taken right. By this means every page will be proved as you proceed, and the balances of ten thousand ledgers, on this plan, could not unobservedly be taken off wrong.

BOSCOVICH (Roger Joseph), one of the most eminent mathematicians and philosophers of the prefent age, was born, of virtuous and pious parents, on

servich the 11th of May 1711, in the city of Ragula, the capital of a small republic of the same name, lying on the eastern coast of the Adriatic Sea. At baptism, the name of Roger was given him, to which he added that of Joseph when he received the facrament (A) of confirmation.

He studied Latin grammar in the schools which were taught by the Jesuits in his native city. Here it foon appeared that he was endued with superior talents for the acquisition of learning He received knowledge with great facility, and retained it with equal firmness. None of his companions more readily perceived the meaning of any precept than he; none more juftly applied general rules to the particular cases contained under them. He enounced his thoughts with great perspicuity, and came soon to compose with propriety and elegance. His application was equal to his capacity, and his progress was rapid. At the beginning of the 15th year of his age, he had already gone through the grammar classes with applause, and had studied rhetoric for some months. His moral behaviour had likewife been very good; he was respectful and obedient to his parents and mafters, affable and obliging to his equals, and exemplary in all the duties of religion. It was now time for him to determine what course he would steer through life; nor did he hefitate long in coming to a refolution.

The Jesuit fathers, by teaching the sciences to youth, were very useful, and at the same time had a fine opportunity of observing their scholars, and of drawing into their fociety those boys who feemed fit for their purpose. Such a subject as the young Boscovich could not elcape their attention. They shewed him particular kindness, to which he was not insensible. He had an ardent thirst for learning; to advance in which he felt himfelf capable; and he thought he could nowhere have a better opportunity of gratifying this laudable inclination than in their order, in which fo many perfons had shone in the republic of letters. Accordingly, with the consent of his parents, he petitioned to be received among them; and his petition was immediately granted, because it was defired by those to whom it was made.

It was a maxim with the Jesuits to place their most eminent subjects at Rome, as it was of importance for them to make a good figure on that great theatre. Wherefore, as Roger's masters had formed great expectations of him, they procured his being called to that city; whither he was fent in the year 1725, and entered the noviceship with great alacrity. This noviceship was a space of two years, in which the candidate made a trial of his new state of life; and in the mean time his new superiors observed him, and deliberated whether or not they would admit him into their body. During these two years, the novice was principally employed in exercises of piety, in studying books of Christian morality, and in becoming perfectly acquainted with the rules and conflitutions of the order. After these two years were past, the Jesuits were willing to retain Boicovich, and he was no less desirous of remaining with them. He therefore passed to the Boscovichschool of rhetoric; in which, for two other years under the most expert masters of the society, young men perfected themselves in the arts of writing and speaking, which was of fo great confequence to perfons who were destined to treat fo much with their neighbours. Here Boscovich became perfectly well acquainted with all the claffical authors, and applied with fome predilection to Latin poetry.

After this he removed from the noviciate to the Roman College, in order to fludy philosophy, which he did for three years. In order to understand the doctrine of physics, it was necessary to premise the knowledge of the elements of geometry, which is also otherwife proper for forming the mind, and for giving to it a true taste for truth. Here it was that our young philosopher came to be in his true element; and it now appeared how extremely fit his genius was for this kind His master, though he was able and expert, instead of leading him on, was scarcely able to keep pace with him, and his condifciples were left far behind. He likewise found the application of the mathematics to natural philosophy pleasant and easy. From all this, before the end of the three years, he had made a great advancement in physical and mathetical knowledge, and his great merit was generally acknowledged by his companions, and well known to his superiors. He had already begun to give private leffons on mathematics.

According to the ordinary course followed by the Jesuits, their young men, after studying philosophy, were wont to be employed in teaching Latin and the belles lettres for the space of five years, that so they might become still better acquainted with polite learning, and arrive at the study of theology and the priesthood at a riper age. But as Roger had discovered extraordinary talents for geometrical studies it was thought by his fuperiors that it would be a pity to detain him from his favourite pursuits in a drudgery for which fo many others were fit enough. He was therefore dispensed with from teaching those schools, and was commanded to commence the study of divinity.

During the four years that he applied to that fublime science, he still found some leifure for geometry and physics; and even before that space was ended, he was named professor of his beloved mathematics.

He was now placed in an office for which he was fuperlatively fit, and for which he had a particular predilection. Besides having seen all the best modern productions on mathematical subjects, he studied diligently the ancient geometricians, and from them learned that exact manner of reasoning which is to be observed in all his works. Although he himself perceived easily the concatenation of mathematical truths, and could follow them into their most abstruse recesses, yet he azcommodated himself with a fatherly condescension to the weaker capacities of his scholars, and made every demonftration clearly intelligible to them. When he per-ceived that any of his disciples were capable of advancing faster than the rest, he himself would propose his

⁽A) For this article we are indebted to a dignified clergyman of the church of Rome, who was one of Boscovich's favourite pupils.

Befovich. giving them private leffons, that fo they might not lofe their time; or he would propose to them proper books, with directions how to fludy them by themselves, being always ready to folve difficulties that might occur to them.

To the end that he might be the more useful to his scholars, he took time from higher pursuits to compose new elements of arithmetic, algebra, plain and solid geometry, and of plain and folieric trigonometry; and although these subjects had been well treated by a great many authors, yet Boscovich's work will always be e-Iteemed by good judges as a mafterly performance, well adapted to the purpose for which it was intended. To this he afterwards added a new exposition of conic sections; in which, from one general definition, he draws, with admirable perspicuity, all the properties of those three most useful curves. He had meditated a complete body of pure and mixed mathematics, in which were to be comprehended treatifes on music, and on civil and military architecture; but from accomplishing this he was prevented by other necessary occupations.

According to the custom of schools, every class in the Roman College, towards the end of the scholastic year, gave to the public specimens of their proficiency. With this view Boscovich published yearly a differtation on some interesting physico-mathematical subject. The · doctrine of this differtation was defended publicly by some of his scholars, assisted by their master. At these literary differtations there was always a numerous concourse of the most learned men in Rome. His new opinions in philotophy were here rigorously examined and warmly controverted by persons well versed in phyfical fludies: but he proposed nothing without folid grounds; he had foreteen all their objections, anfwered them victoriously, and always came off with great applause and increase of reputation. He published likewife differtations on other occasions; and these works, though small in fize, are very valuable both for the matter they contain, and also for the manner in which it is treated. The principal subjects of these disfertations are the following: The spots in the sun; the transit of mercury under the sun; the geometrical construction of spheric trigonometry; the aurora borealis; a new use of the telescope for the determination of celestial objects; the figure of the earth; the arguments made use of by the ancients to prove the rotundity of the fame; the circles which are called ofculators; the motion of bodies projected in a space void of refistance; the nature of infinites and of infinitely little quantities; the inequality of gravity in different parts of the earth; the annual aberration of the fixed stars; the limits of the certainty to which aftronomical observations can arrive; a discussion on the whole of astronomy; the motion of a body attracted by certain forces towards an immoveable centre in spaces void of refistance; a mechanical problem on the folid of greatest attraction; a new method of using the observation of - the phases in the lunar eclipses; the cycloid; the logiftic and certain other curve lines; the forces that are called living; the comets; the flux and reflux of the fea; light; whirlwinds; a demonstration and illustration of a passage in Newton concerning the rainbow: the dem aftration and illustration of a method given by Euler regarding the calculation of fractions; the determination of the orbits of a planet by means of ca-

toptrics, certain conditions of its motions being given; Boscovici the centre of gravity and that of magnitude; the atmosphere of the moon; the law of continuity, and the confequences of it in the elements of matter and their forces; the law of the forces that exist in nature; lenses and dioptrical telescopes; the perturbation which appears to be caused mutually by Jupiter and Saturn, and that chiefly about the time of their conjunction; the divisibility of matter and the elements of bodies; the objective micrometer; -- besides other subjects of the like nature, of which he has treated in separate pieces, or in communications interted in the transactions of literary focieties or academies, he being a member of those that are most famous in Europe. It was in some of the abovementioned differtations that Boscovich made known first to the world his sentiments concerning the nature of body, which he afterwards digested into a regular theory, which is juftly become fo famous among the learned.

Father Noceti, another Jesuit, had composed two excellent poems on the rainbow and the aurora borealis. These poems were published with learned annotations by Boscovich; in which, among other things, he with great tagacity discovers errors in optics into which De Dominis, Kepler, and others, had tallen.

His countryman, Benedict Stay, after having published the philosophy of Descartes in Latin verse, attempted the same with regard to the more modern and more true philotophy, and has executed it with wonderful fuccefs, to the admiration of all good judges. The two first volumes of this elegant and accurate work were published with annotations and supplements by Boscovich. These supplements are so many short differtations on the most important parts of physics and mathematics. Here is to be found a folution of the problem of the centre of oscillation, to which Huygens had come by a wrong method; here he confutes Euler, who had imagined that the vis inertia was necessary in matter; here he refutes the ingenious efforts of Riccati on the Leibnizian opinion of the forces called living. He likewife shews the falsehood of the mathematical prejudice, according to which the right line is confidered as effentially more fimple than curves, and makes it appear, that the notion of the faid right line is commonly accompanied with many paradoxes. He demonstrates by the doctrine of combinations, some beautiful theorems concerning the space occupied by the small maffes of body, with many ufeful observations on space and time.

Benedict XIV. who was a great encourager of learning, and a beneficent patron of learned men, was not ignorant how valuable a subject Rome possessed in Boscovich; and this pope gave him many proofs of the esteem he had for him. 'I'wo fissures which had been perceived in the capola of the church of St Peter's on the Vatican had occasioned tome alarm. The pope defired Boscovich and some other mathematicians to make their observations and give their opinion on the same. They obeyed, and their opinion was printed. They shewed that there was no cause to apprehend danger; but, for greater fecurity, they proposed certain precautions, which were adopted and put in exe-

The high opinion which the pope had formed of his talents, and the favour in which he was with Cardinal

frovich Valenti, minister of state, proved hindrances to his go- Tuscany, resided. He was so successful in this nego. Boscovich. ing to America, for which a proposal was made to him by the court of Lifbon. Some differences had long fublisted between Spain and Portugal concerning the boundaries of their respective dominions in that great continent; and John V. of Portugal wished that Boscovich would go over and make a topographical furvey of the country in dispute. He was not unwilling to undertake fuch a task, which was entirely to his taste: and he was refolved at the fame time to measure a degree of the meridian in Brazil, which might be compared with that measured at Quito by the French academicians Bouguer and Condamine, with the Spaniards Ulloa and Doy. But the pope hearing of this propofal, fignified to the Portuguese minister at Rome, that his mafter must needs excuse him for detaining Boscovich in Italy, where he had occasion for him, and could by no means confent to part with him.

Accordingly a commission was given to Boscovich by Benedict to correct the maps of the papal estate, and to measure a degree of the meridian passing thro' the fame. This he performed with great accuracy, assisted by F. Christopher Maire an English Jesuit, and likewise a great mathematician. Their map was engraved at Rome, and is perhaps the most exact piece of the kind that ever was printed, as all the places are laid down from triangular observations made by the ablest hands. Boscovich also published, in a quarto volume in Latin, an account of the whole expedition, which appeared at Rome in the year 1755, and was afterwards printed at Paris in French in the year 1770. Here he gives a detail of their observations and of the methods they followed, and likewife of the difficulties they encountered, and how they were furmounted. One of these embarrassed them a good deal at the time, but was afterwards matter of diversion to them and others Some of the inhabitants of the Apeninnes, feeing them pass from hill to hill with poles and strange machines, imagined that they were magicians come among their mountains in fearch of hidden treasures, of which they had fome traditions: and as tempetts of thunder and hail happened about the fame time, they supposed that these calamities were caused by the forceries of their new visitants. They therefore infifted that Boscovich and Maire thould depart; and it was not easy to convince them that their operations were harmless. In this work there is inserted a description of the instruments made use of in determining the extent of the degree of the meridian; and the whole work may be extremely use-

ful to practical geometricians and astronomers. In the year 1757 the republic of Lucca entrusted Boscovich with the management of an affair which was to them of confiderable importance. Between that republic and the regeney of Tulcany there had arisen a diagreeable dispute concerning the draining of a lake, and the direction to be given to some waters near the translation of it into French has likewise been published chose our philosopher to treat of this business on their part. He repaired to the spot, considered it attentively, and drew up a writing, accompanied with a map, to shew more clearly what appeared to him most equitable and most advantageous for both parties. In order to enforce his reasons the more effectually, it was he proposes a theorem, which is his own, concerning thought proper that he should go to Vienna, where the

ciation, that he obtained every thing that Lucca defired, and at the fame time acquired great efteem at the imperial court. In proof of this, the empress queen made his opinion be asked concerning the stability of the Ceiarean library, and the repairs to be made in it; which he gave in writing, and it was received with thanks, as being very well grounded.

When he had concluded the affair which had brought him to Vienna, he forefaw that, for a month or two, the snows in the Alps would not allow him to return to Italy. He therefore resolved to employ that time in completing his lystem of natural philosophy, on which he had been meditating for the space of thirteen years. He published his work on that great subject in the beginning of the year 1758, in the abovementioned city. We shall in the end give an account of that celebrated fystem, and here go on with our narration.

On his return to Lucca, he not only met with the approbation of all he had done for the interest of the republic, but also the senate, in testimony of their gratitude, made him prefents, and inrolled him in the number of their nobility, which was the greatest honour they had in their power to confer on him.

He, who was thus useful to foreigners, could not refuse to be serviceable to his own country when an occasion of being so offered itself. The British ministry had been informed, that ships of war, for the French, had been built and fitted out in the fea-ports of Ragufa, and had fignified their displeasure on that account. . This occasioned uneafiness to the senate of Raguia, as their subjects are very sea-faring, and much employed in the carrying trade; and therefore it would have been inconvenient for them to have caused any disgust against them in the principal maritime power. Their countryman Boscovich was desired to go to London, in order to fatisfy that court on the abovementioned head; and with this defire he complied cheerfully on many accounts. His success at London was equal to that at Vienna. He pleaded the cause of his countrymen effectually there, and that without giving any offence to the French, with whom Ragusa soon after entered into a treaty of commerce.

Boscovich came to London the more willingly, as he was defirous of converfing with the learned men of Britain. He was received by the prefident and principal members of the Royal Society with great respect; and to that great body he dedicated his poem on the eelipses of the sun and moon, which was printed on this occasion at London, in the year 1760. This is one of his works on which he himself put the greatest value, and it has been much esteemed by the learned. An edition of it was published at Venice the year following, and a third at Paris, which is the most correct: a boundaries of the two states. The Lucchese senate at Paris. In this very elegant Latin poem he gives an exact compend of aftronomy, which leives as an introduction to the subject; he then explains all that belongs to the doctrine of eelipses, and their use in geography; he confiders the phenomena that are observed in the eclipses of the sun, and likewise of the moon; the distribution of light refracted from the atmoemperor Francis I. who was likewife grand duke of Iphere of the earth by the shadow of the moon, which

Rofcovich happens in the lunar eclipses; he explains the phenomenon of the reddish colour which often appears in the moon when she is eclipsed, of which a sufficient explication had not before been given: this the author draws from the fundamental doctrine of Newton's theory concerning light and colours; and hence takes occasion to give a clear idea of the principal consequences of the faid theory. All this is clothed with a beautiful poetical dress, and is adorned with pleasant episodes, not to mention the learned annotations which are fubjoined. This poem was composed, for the most part, whilst the author was in journeys, or by way of amusement, when he was obliged to wait for the opportunities of making aftronomical observations.

The fellows of the Royal Society invited Boscovich to accompany some of their number to America, to obferve the transit of Venus, which was to happen in the year 1762; but being otherwise engaged, he could not accept of that invitation. He intended, however, by all means to observe that remarkable phenomenon, and had fixed on Constantinople as a proper place for doing fo. He was conducted thither in a Venetian man of war, and much honoured by one of the baylos of that republic, who commanded the veffel; but, to his great regret, they arrived too late. He returned, by land, in the company of the English ambassador; and a relation of that journey was published in French and afterwards in

During these journeys, Boscovich's place in the Roman College was well filled by fome of those whom he himself had trained up in mathematical learning. He was now called by the senate of Milan to teach mathematics in the university of Pavia, with the offer of a very confiderable falary. He and his fuperiors thought proper to accede to this propofal, and he was received without being subjected to any previous examination; which was always observed, excepting in such an extraordinary cafe, by the decrees of the university. Here he taught, with great applause, for the space of six years, having at the same time the care of the observatory of the Royal College of Brera. About the year 1770, the empress queen made him professor of astronomy and optics in the Palatine schools of Milan; requiring of him, however, that he should continue to improve the observatory of Brera; which, under his direction, became one of the most perfect in Europe.

Here he was extremely happy, teaching the sciences, applying to his favourite studies, and conversing and corresponding with men of learning and of polished manners; when an event happened which caused to him the most fensible affliction. In the year 1773, the fociety to which he belonged, and to which he had been from his youth warmly attached, was, to his great regret and disappointment, abolished. They who had been Jesuits were allowed no longer to teach publicly; nor was there any exception made in favour of Boscovich, neither (fuch was his humour then) would he have accepted of it, though it had been offered him. Proposals were made to him by several persons of diftinction; and, after some deliberation, he chose Paris for his place of abode; to which he was induced by the circumstance of his being intimately acquainted with the prime minister at that court. He had not been many months at Paris when the university of Pira

fent him an invitation to go thither, in order to pro- Boscovich, fels astronomy. But the French minister, understanding this, declared to the minister of Tuscany, that it was the intention of his most Christian majesty to make his dominions agreeable to Boscovich, by giving him liberal appointments. In fact he was foon naturalized, and two large pensions were bestowed on him; the one as an honourable support, to the end that he might profecute his fublime studies at his ease and in affluence; the other as a falary annexed to a new office, created in his favour, under the name of Director of Optics for the Sea Service, and with the folc obligation of perfecting the lenses which are used in achromatical telescopes.

At Paris he remained ten years, applying principally to optics, and much regarded, not only by the most reasonable men of letters, but likewise by the princes and ministers, both of France and of other nations. But the greatest men are not exempt from being envied. Some of the French were displeased that a foreigner should appear superior to themselves; others of them could not forget that Boscovich had discovered and exposed their mittakes. The irreligion which prevailed too much among those who bore the name of philosophers, was disagreeable to him. These, and other such circumstances, made him wearied of Paris, and he defired to revitit his friends in Italy; for which purpose he obtained leave of absence for two years.

The first place in Italy in which he made any stay was at Bassano, a town in the territories of Venice. Here, mindful of his obligations, he printed what he had been preparing for the press during his stay in France; and this composes five volumes in large octavo, and is a treafure of optical and aftronomical knowledge. The fubjects treated of in these volumes are as follow: A new instrument for determining the refracting and diverging forces of diaphonous bodies; a demonstration of the falsehood of the Newtonian analogy between light and found; the algebraic formulæ regarding the focuses of lenses, and their applications for calculating the sphericity of those which are to be used in achromatical telescopes; the corrections to be made in occular lenses, and the error of the sphericity of certain glasses; the causes which hinder the exact union of the folar rays by means of the great burning glasses, and the determination of the loss arifing from it; the method of determining the different velocities of light passing through different mediums by means of two dioptrical telescopes, one common, the other of a new kind, containing water between the objective glass and the place of the image; a new kind of objective micrometers; the defects and inutility of a dioptrical telescope proposed and made at Paris, which gives two images of the same object, the one direct, the other inverse, with two contrary motions of moveable objects; masses floating in the atmosphere, as hail of an extraordinary fize, feen on the fun with the telescope, and resembling spots; the astronomical refractions, and various methods for determining them; various methods for determining the orbits of comets and of the new planet, with copious applications of these doctrines to other astronomical subjects, and still more generally to geometry and to the science of calculation; the errors, the rectifications, and the use of quadrants, of fextants, of astronomical sectors, of the meridian line, of telescopes called the instruments of transits, of the meridian, Bescovich meridian, and of the parallactic machine; the trigono would take occasion to tax him with ingratitude, and Bescovich. in altronomy; the use of the micrometical rhombus, ex- and other such thoughts, occasioned a great perplexity tended to whatever oblique position; the error arising from refractions in using the astronomical ring for a sundial, and the correction to be made; the appearing and the disappearing of Saturn's ring; the methods of determining the rotation of the fun by means of the spots, proposed formerly by the author, and now perfected: the greatest exactness possible in determining the length of a pendulum of cillating every fecond of middle time by the comparison of terrestrial and celestial gravity; a compend of aftronomy for the use of the marine, containing the elements of the heavenly motions, and of the aftronomical instruments to be explained to a prince in the course of one month; a method for determining the altitude of the poles with the greatest exactness, by means of a gnomou alone, where other instruments are not to be had; the determination of the illuminated edge of the moon to be observed on the meridian; a method of using the retrograde return of Venus to the fame longitude, for determining the less certain elements of her orbit; a method for correcting the elements of a comet, of which the longitude of the node is given, and the inclination of the orbit has been found nearly; another method for the same purpose, and for finding the elliptical orbit, when the parabolic one does not agree with the observations; a method for correcting the elements of a planet by three observations; the projection of an orbit inclined in the plane of the ecliptic; the projection of an orbit inclined in any other plane; the calculation of the aberration of the stars, arising from the fuccessive propagation of light; fome beautiful theorems belonging to triangles, which are of great use in aftronomy, reduced to most simple demonstrations.

After having feen the impression of these five volumes finished, Boscovich left Bassano, made an excursion to Rome, and visited his old friends there and in other places of Italy. He then took up his abode at Milan, and applied to the revising of some of his old works, and to the composing of new ones. He set himself particularly to prepare annotations and supplements to the remaining two volumes of Stay's Modern Philosophy, which he had not had time to publish sooner, and which

he lived not to publish.

He was happy at Milan in the neighbourhood of Brera, where was his favourite observatory; and in the company of many friends, who were become the more dear to him by his long absence from them. But he began to confider, with grief, that his two years of abfence were drawing to an end. He was very unwilling to leave Italy and return to France. He thought of applying for a prolongation of his absence; he thought of making interest at the Imperial court for some honourable commission, which might be a pretext to him for remaining at Milan; but he was afraid that the proposal of never returning to France might appear indelicate and ungrateful to a nation from which he was receiving confiderable pensions. He apprehended that those persons at Paris who had before opposed him,

metrical differential formulæ, which are of so much use that hence his reputation would be tarnished. These, of mind, which was followed by a deep melancholy; and this could not be alleviated by the advice and comfort of his friends, because by degrees he became incapable of hearing reason, his ideas being quite confused, and his imagination disordered. To this disagreeable change the state of his health perhaps contributed. A gout had been wandering for some time through his body, and he had caught a fevere cold; nor would he admit of medical affiftance, of which he had always been very diffident. It may also be that his long and intense application had hurt the organs of the brain, which in some manner are subservient to the use of reafon as long as the foul is united to the body. Be that as it will, during the last five months of his life this great man, who had been fo far tuperior in reasoning to his ordinary fellow creatures, was much inferior to every one of them who is endued with the right use of the understanding. He had indeed some lucid intervals, and once there were hopes of a recovery; but he foon relapsed, and an imposthume breaking in his breast, put an end to his mortal existence. He died at Milan on the 13th of February 1787, in the 76th year of his age.

He was tall in stature, of a robust constitution, of a pale complexion. His countenance was rather long, and was expressive of cheerfulness and good humour. He was open, fincere, communicative, and benevolent. His friends fometimes regretted that he appeared to be too irritable, and too fenfible of what might feem an affront or neglect, which gave himself unnecessary uneafiness. He was always unstained in his morals, obcdient to his superiors, and exact in the performance of all Christian duties, as became a Catholic priest, and in the observance of the particular rules of his order. His great knowledge of the works of nature made him entertain the highest admiration of the power and wisdom of their Creator. He faw the necessity and advantages of a divine revelation, and was fincerely attached to the Christian religion, having a fovereign contempt of the prefumption and foolish pride of unbelievers; and being fully perfuaded that we cannot make a more noble use of our understanding than by subjecting it humbly to the authority of the Supreme Being, who knows num-berless truths far beyond the utmost limits of our narrow comprehension, and who may justly require our belief of any of them that he sees sit to propose to us.

The death of our philosopher, who truly deserved that name, was heard with regret by the learned through Europe, and more than ordinary respect has been paid to his memory. At Ragusa funeral exequies were performed for him with great folemnity by order of the fenate, who affifted at them in a body; on which occasion an eloquent oration in praise of him was pronounced. By a decree of the same senate, a Latin infcription to his honour, engraved on marble, was placed in the principal church of their city. Of this inferip-

tion the following is a copy:

Publice. Delatum Ejusdem l'empli Curatores Ex. Senatus. Confulto M. P. P.

This inscription was composed by his friend and coun- have already taken notice. We have mentioned, r. His tryman the celebrated poet Benedict Stay. Zamagna, Elements of Mathematics, with his Treatife on Conic another of his countrymen, who had likewise been his Sections; 2. His many differtations published during fellow jesuit, published a panegyric on him in elegant his professorship in the Roman college; 3. His account Latin. A short encomium of him is to be found in the of his Survey of the Pope's Estate; 4. His Theory of Estratto della Litteratura Europea; and another, in form Natural Philosophy; 5. His Poem on the Eclipses; of a letter, was directed by M. de la Lande to the Pa- 6. His five volumes printed at Baffano. risian journalists, and by them given to the public. A third was published at Milan by the Abbate Ricca; this last chiefly use has been made here

To these we may add his hydrodynamical pieces. He more tull elogium has been written by M. Fabroni; and had made a particular study of the force of running waanother is to be met with in the journal of Modena; a ter, and of its effects in rivers; and he was often confulted concerning the best means to prevent rivers from and a fourth at Naples by the Dr Julius Bajamonti, of corroding their banks, and from overflowing the neighwhich a fecond edition was made in the year 1790. Of bouring plains, which o'ten happens in Italy, where the Alps and Apennines pour down fo many impetuous But what must secure to Boscovich the esteem of po- streams. He gave a writing on the damages done by flerity are his works, of the greater part of which we the Tiber at Porto Felice; another on the project of

turning

Boscovich. turning the navigation to Rome from Fiumicino to Mac- mits as the distances are diminished, and is consequent. Boscovich carefe; a third on two torrents in the territory of Pe-Tagia; a fourth on the bulwarks on the river Panaro; a fifth on the river Sidone, in the territory of Placentia: a fixth on the entrance into the fea of the Adige. He wrote other fuch works on the bulwarks of the Po: on the harbours of Ancona, of Rimini, of Magna Vacca, and Savona, befides others, almost all which were printed. He had likewise received a commission from Clement XIII. to visit the Pomptin lakes, on the draining of which he drew up his opinion in writing, to which he added further elucidations at the defire of Pius VI. On these occasions he showed how useful philosophy may be to the public; and of this he gave another proof when it was referred entirely to his judgement to determine whether or not the cupola of the cathedral of Milan could bear the weight of a very high fpire, which it was proposed to raise on it, and which was actually erected according to his directions.

His application to abitrule studies did not hinder him from paying some attention to what is more pleafant. We have feen that he was a poet: he was also well acquainted with history, and particularly with that of the Greeks and Romans, and with their antiquities. He wrote a differtation on an ancient villa discovered in his time upon the Tufculan Hill, and on an ancient dial found there, which differtation was published at Rome in a literary journal. He wrote likewise three letters on the obelifk of Cæfar Augustus, two of which were printed with his own name, and the third under the name of another.

Besides all these works that were given to the public in his lifetime, many writings of his remained in manufcript in the hands of different persons, and particularly with his friend M. Gaetani, and many more with Count Michael de Sorgo, a Ragusan senator, who inherited all his papers that were in his own hands at his death. These, it is hoped, have either been already sent to the prets or will be to; as nothing came from the pen of Boscovich which was not useful and deserving to see the light.

It now remains that we give an account of his THEORY OF NATURAL PHILOSOPHY; and in doing this we shall, in the first place, lay before our readers a view of this system. We shall, in the second place, relate, from what principles and by what steps it was deduced. We shall, thirdly, take notice of the principal objections made to it, and subjoin the author's answers to the same. We shall, finally, shew how happily it may be applied to explain the general properties of matter, as well as the particular qualities of all the classes of bodies, which have been examined according to what it teaches.

I. In this fystem, therefore, the whole mass of matter, scovich's of which all the bodies of the universe are composed, confifts of an exceeding great, yet still finite, number of fimple, indivisible, inextended, atoms. These atoms are lofophy. endued with repulsive and attractive forces, which vary and change from the one to the other, according to the distance between them, in the following manner: In the least and innermost distances they repel one another; and this repulfive force increases beyond all li-

ew of

tem of

ly sufficient for extinguishing the greatest velocity, and System of for preventing the contact of the atoms. In the fen-philosophy. fible distances, this force is attractive, and decreases, at least fensibly, as the squares of the distances increase, constituting universal gravity, and extending beyond the sphere of the most distant comets. Between this innermost repulsive force and the outermost attractive one, in the infensible distances, many varieties and changes of the force, or determination to motion, take place: for the repulfive force decreases as the distance increases. At a certain distance it comes to vanish entirely; and, when that distance is increased, attraction begins, increases, becomes less, vanishes; and the distance becoming greater, the force becomes repulfive, increases. lessens, and vanishes as before. Many varieties and changes of this kind happen in the infensible distances, sometimes more rapidly, fometimes more flowly, and fometimes one of the forces may come to nothing, and then return back to the same without passing to the other. For all this there is full room in the distances that are infensible to us, seeing the least part of space is divisible in infinitum. Besides these repulsive and attractive forces, our atoms have that vis inertiae which is admitted by almost all modern philosophers. These atoms, endued with these forces, constitute the whole substance of Boscovich's system; which, however simple and short it may appear to be, has numberless and very wonderful consequences, as we shall see afterwards. But, that The whole a more clear idea of the whole theory may be eafily theory exformed, we shall make use of a geometrical figure well a geometrical accommodated to that purpose. The right line C'AC cal curve. is an axis, from which, in the point A, is drawn the Plate VI. right line AB at right angles. AB is confidered as an fig. 6. asymptote; on each fide of which the two curves, quite fimilar and equal, DEFGHIKLMNOPQRSTVU on the one fide, and D'E'F'G' on the other, are placed. Now, if ED be supposed to be asymptotical, and be extended, it will still approach to BA, but will never come to touch it. This curve ED approaches to the axis C'C, comes to it in E, cuts it and departs to a certain distance in F, after which it again approaches the same axis and cuts it in G. In like manner it forms the arches GHI, IKL, LMN, NOP, PQL. At last it goes on in 'Tps V, which is asymptotical, and approaches to the axis; fo that the diftances from it are in a duplicate reciprocal proportion of the distances from the right line BA. If from any points of the axis, as from a, b, d, we raife the perpendiculars a g, br, db, the fegments of the axis A a, A b, Ad, are called abscisses, and represent the diftances of any two points of matter from one another; and the perpendiculars ag, br, db, are called ordinates, and exhibit the repulsive or attractive force, according as it lies on the same side with D, or on the other side of the axis.

Now it is evident that, in this form of the curve line, the ordinate ag will be increased beyond whatever limits, if the absciss Aa be lessened likewise beyond whatever limits; that if this abscils be increased to A b, the ordinate will be leffened, and will pass into br, which will still be lessened as it approaches from b to E, where it will come to nothing; that then, the axis being increased to A d, the ordinate will change its direction into bh, and, on the opposite side, will increase at first

will vanish and change its directions in all the sections I. L., N, P, R, until the ordinates op, vs, become of a constant direction, and decrease, at least fensibly, in a reciprocal duplicate proportion of the abscisses A o, A v. Wherefore, it is manifest, that by such a curve are expressed our forces; at first repulsive, and increasing beyond all limits, the distances being lessened in like manner, and which decrease, the same distances being augmented; then vanish, change their direction, and become attractive; vanish again, and become repulsive; till at last, at sensible distances, they remain on the side opposite to D, and are attractive in a duplicate reciprocal proportion of the distances.

We may also observe, that the ordinates may increase or decrease rapidly, as in y v, zt, or slowly, as in vx, zc; and, consequently, that the forces may increase or decrease in like manner. We may add, that the curve may return back without interfecting, or even touching, the axis, as in f, and may return after having touched

the fame axis.

Although this curve expresses very clearly the repulfive and attractive forces of our system, yet, at first fight, it may appear to be a complicated irregular line. But the author shews that his curve is uniform and regular, and may be expressed by one uniform algebraical equation; which it will be necessary for us to confider, in order to give satisfaction to our readers, and to do justice to the theory.

Wherefore, from what we have feen, the curve must city of this have the following fix conditions: 1/t, It must be regular curve pro- and simple, and not composed of an aggregate of arches of different curves. 2dly, It is necessary that it cut the axis C'AC in certain given points only, at two equal distances on each fide AE', AE, AG', AG, and fo on. 3dly, That to every absciss an ordinate correspond. 4thly, That if we take equal abscisses on each side of A, they have equal ordinates. 5thly, That the right line AB be an asymptote, the area BAED being asymptotical, and consequently infinite. 6thly, That the arches terminated by any two interfections may be varied at pleasure, and recede to any distance from the axis C'AC, and approach at pleasure to whatever arches of whatever curves, cutting them, touching them, or ofculating them, in any place and manner.

In order to find an algebraical formula expressing the nature of a curve line that would answer all these fix conditions, let us call the ordinate y, the absciss x, and let it be made x = z. Then let us take the values of all the absciffes AE, AG, AI, &c. with the negative fign, and let the fum of the squares of all these values be called a, the fum of the products of every two fquares b, the fum of the products of every three, c, and fo on; and let the product of all of them be called f, and the number of the same values m. All this being supposed, let it be made $z^m + az^{m-1} + bz^{m-1}$ $+cz^{m-3}$ &c. +f=P. If we suppose P equal to nothing, it is clear that all the roots of that equation will be real and positive; that is, the squares only of the quantities AE, AG, AI, &c. which will be the values of z; and therefore, as it is $x = \pm \sqrt{z}$, because it is xx = z, it is likewise clear that the values of x will be both AE, AG, AI, positive, and A'E', A'G', &c. ne. Boscovich's

This being done, let any quantity be multiplied by Philotophy, z, providing it hath no common divisor with P, left z vanishing, it likewise might vanish; and having made x an infinitesim of the first order, it may become an infinitesim of the same, or of a lower order, as will be whatever formula $z^r + gz^{r-1} + hz^{r-2} &c. + l$; which, being supposed equal to o, may have as many imaginary, and as many and whatever real roots, providing none of them be those of AG, AE, AI, &c. either positive or negative. If then the whole formula be multiplied by z, let this product be called Q.

B

If we make P-Qf=o, this equation will fatisfy the five first conditions above mentioned; and the value of Q being properly determined, the fixth condition

also may be complied with.

For, in the first place, seeing the value P and O are made equal to o, they have no common root, and therefore no common divisor. Hence this equation cannot be reduced to two by division; and therefore it is not composed of two equations, but is simple, and therefore exhibits one simple continued curve, which is not composed of any others; which is the first condition.

Secondly, The curve thus expressed will cut the axis C'AC in all the points E', G, I, &c. G', &c. and in them only: for it will cut that exis only in those points in which y = 0, and in all of them. Moreover, where it will be y = o, it will also be Q y = o; and therefore, because of P - Q y = o, it will be P = o. But this will happen only in those points in which z will be one of the roots of the equation P = o; that is, as we have feen above, in the points E, G, I, or E', G, &c.: wherefore, only in those points will y vanish, and the curve cut the axis. Again, that the same curve will cut it in all these points, is clear from this, that in them all it will be P = o. Wherefore it will likewise be Q y = o; but it will not be Q = o, feeing there is no common root of the equations P = 0 and Q = 0: it must therefore be y = o, and the curve will cut the axis: and thus the fecond condition is fatisfied.

Besides, whereas it is P-Q = 0, it will be $y = \frac{1}{Q}$. the absciss x being, however, determined, we will have a certain determinate quantity for z; and thus P, Q, will be determined, and the only two of the kind. Wherefore y also will be sole and determined; and therefore to every absciss z, one only ordinate y will correspond. This is the third condition.

Again, whether x be assumed positive or negative, providing it be of the fame length, still the value z=xx will be the same, and therefore the values of both P and Q will be the fame: wherefore y will still be the Taking, therefore, equal abscisses z on both fides of A, the one positive, the other negative, they will have equal corresponding ordinates. This is the

fourth condition.

If x be leffened beyond all limits, whether it be pofitive or negative, z likewise will be lessened beyond all limits, and will become an infinitefin of the fecond order: wherefore, in the value P, all the terms will decrease in infinitum, except in y, because all the rest befides it are multiplied by z; and thus the value P will be as yet finite. But the value Q, which has the for-

wich's mula multiplied by z, will be lessened in infinitum, and m of ural will be an infinitefim of the second order: therefore fophy.

= y will be augmented in infinitum, so as to become an infinite of the second order. Wherefore the curve will have the right line AB for an asymptote, and the area BAED will increase in infinitum: and if the ordinate y be assumed positive on the side AB, and express repulfive forces, the alymptotic arch ED will lie on the fame fide AB. This is the fifth condition.

Now the value Q can be varied in infinite manners; fo that still the conditions for which it was assumed may be fulfilled; and therefore the arches of the curve intercepted by the interfections may be varied in infinite manners; fo that the first five conditions of the curve may be implemented: whence it follows, that they may be fo varied that the fixth condition may also be

answered. For if there be given, however many, and whatever arches of whatever curve, providing they be such that they recede always from the afymptote AB, and thus no right line parallel to that afymptote cut these arches in more than one point, and in them let there be taken as many points as you pleafe, and as near one another; it will be easy to assume such a value of P, that the curve shall pass through all these points, and the fame may be varied infinitely; so that still the curve

will pass through all the same points.

Let the number of points affumed be what you pleafe = r, and, from every one of fuch points, let right lines be drawn parallel to AB, as far as the axis C'AC, which must be the ordinates of the curve that is fought; and let the abscisses from A to the said ordinates be called M', M2, M3, &c. and the ordinates 'N', 'N2, 'N3, &c. Let there now be taken a certain quantity Azr+Bzr-x $+Cz^{r-2}+Gz$, and let this quantity be supposed equal to R. Then let another such quantity T be assumed, fo that z vanishing, whatsoever term of it may vanish, and fo that there be no common divifor of the value of P, and of the value of R+T; which may be eafily done, feeing all the divifors of the quantity P are known. Let it now be made Q = R + T, and then the equation of the curve will be P - R y - T y = 0. After this, let there be put in the equation M1, M2, M3, fuccessively for x, and N1, N2, N3, &c. for y; we will have a number of equations equal to r, which will contain the values of A, B, C, G, each of them of one dimension, in number likewise equal to r; and, besides, we will have the given values of M1, M2, &c. N1, N2, N3, &c. and the arbitrary values which in T are the coefficients of z.

By these equations, which are in number r, it will be easy to determine the values A, B, C, G, which are likewise in number r, assuming in the first equation, according to the usual method, the value A, and subflituting it in all the following equations: by which means the equations will become r-1. Thefe, again, by throwing out the value B, will be reduced to r-2, and so on until we come to one only; in which the value Q being determined by means of it, going back, all the preceding values will be determined, one by each equation.

The values A, B, C, G, being in this manner determined, in the equation P - R y - T y = 0, or P - R y = 0, or Qy =0, it is clear that, the values M1, M2, M3, &c.

being fucceffively put for x, the values of the ordinate Boscovich's y must fucceffively be N1, N2, N3, &c.; and, there- System of fore, that the curve must pass through these given points Philosophy. in those given curves; and still the value Q will have. all the preceding conditions. For z being leffened beyond whatever limits, every one of its terms will be leffened beyond whatever limits, feeing all the terms of the value of T are lessened which were thus assumed, and likewise the terms of the value R are lessened, which are all multiplied by z; and, besides this, there will be no common divisor of the quantities P and Q, feeing there is none of the quantity P and R+T'.

But if two of the nearest of the points assumed in the arches of the curves, on the fame fide of the axis, be fupposed to accede to one another beyond whatever limits, and at laft to coincide, which will be done by making two Mequal, and likewisetwo N equal; then the curve sought will touch the arch of the given curve; and if three fuch points coincide, they will ofculate it: nay, as many points as we pleafe may be made to meet together where we please; and thus we may have of ulations of what order we please, and as near one another as we please, the arch of the given curve approaching as we please, and at whatever distances we please, to whatever arches of whatever curves, and yet still preserving all the fix conditions required for expressing the law of the repulfive and attractive forces. And whereas the value of T can be varied in infinite manners, the same may be done in an infinite number of ways; and therefore a fimple curve, answering the given conditions, may be found out in an infinite number of ways. Q. E. F.

What we have faid will, we hope, fatisfy our readers, and especially those of them who are in the least acquainted with high geometry, that Boscovich's curve is fimple, regular, and uniform; and that therefore the law of repulfive and attractive forces, expressed by it, is

fimple and regular.

II. If this system were a mere hypothesis, it would still be very ingenious, and, from what we shall say afterwards, would ftill be well adapted for explaining the phenomena of nature. But its author is far from looking upon it as an arbitrary supposition; he affures us that he was led to it by a chain of strict reasoning, from evident principles. We shall now give an abridgement of that reasoning from his Differtations on the Law of Continuity, and from his Theory of Natural Philosophy.

He tells us, then, that in the examination of Leib-Proots of nitz's opinion of the vires viva, he came to confider the theory. the collision of bodies, and took for example two equal bodies, A proceeding with fix degrees of velocity, and B following with the velocity of 12: after the collifion, they proceed jointly with the common velocity 9. Now, in the moment of collision, it either happens that A passes abruptly from the velocity 6 to the velocity 9, without passing through the velocity 7 and 8, and B passes from 12 of velocity to 9, without passing through 11 and 10; or elfe there must be some cause which accelerates the one and retards the other before they come to contact. In the first case, the law of continuity is broken; in the second, immediate contact of bodies would be rejected. Maclaurin faw this difficulty, and mentioned it in his work on Newton's Discoveries, l. 1. c. 4. He, not having courage to recede from the common opinion, allowed a breach, in fuch cases, of the law of continuity; but Boscovich

maintains

Boscovich's maintains the universality of the law of continuity; and System of holds, that no bodies touch one another really and ma-Philosophy, thematically, but only physically and tensibly to us. The law of continuity is that by which variable quan-

The law of tities, passing from one magnitude to another, pass through all the intermediate magnitudes, without ever abruptly paffing over any of them. This law Boscovich proves to be universal, in the first place, from induction. Thus we see that the distances of two bodies can never be changed without their passing through all the intermediate distances. We see the planets move with different velocities and directions; but in this they still observe the law of continuity. In heavy bodies projected, the velocity decreases and increases through all the intermediate velocities: the fame happens with regard to elasticity and magnetism. No body becomes more or less dense without passing through the intermediate densities. The light of the day increases in the morning and decreases at night through all the intermediate possible degrees. In a word, if we go through all nature, we shall see the law of continuity strictly take place, if all things be rightly confidered. It is true, we sometimes make abrupt passages in our minds; as when we compare the length of one day with that of another immediately following, and fay that the fecond is two or three minutes longer or shorter than the former, paffing all at once, in our way of speaking, round the globe; but if we take all the longitudes, we shall find days of all the intermediate lengths. We likewise fometimes confound a quick motion with an inftantaneous one: thus, we are apt to imagine that the ball is thrown abruptly out of the gun; but, in truth, some space of time is required for the gradual inflammation of the powder, for the rarefaction of the air, and for the communication of motion to the ball. In like manner, all the objections made against the law of continuity may be folved to fatisfaction.

A breach of possible.

proved.

But however strong this argument from judgment this law im-may appear to be, yet Boscovich goes farther, and maintains, that a breach of this law, in the proper cases, is metaphyfically impossible. This argument he draws from the very nature of continuity. It is effential to continuity that, where one part of the thing continued ends and another part begins, the limit be common to both. Thus, when a geometrical line is divided into two, an indivisible point is the common limit of both: thus time is continued; and therefore where one hour ends, another immediately begins, and the common limit is an indivisible instant. Now, as all variations in variable quantities are made in time, they all partake of its continuity; and hence none of them can haften by an abrupt passage from one magnitude to another, without paffing through the intermediate magnitudes. As we cannot pass from the fixth hour to the ninth without paffing through the seventh, and eighth; because, if we did, there would be a common limit between the fixth hour and the ninth, which is impossible; so like. wife you cannot go from the distance 6 to the distance 9 without passing through the distances 7 and 8; because, if you did, in the instant of passage you would be both at the distance 6 and at the distance 9, which is impossible. In like manner, a body that is condensed or rarefied cannot pass from the density 6 to the denfity 9, or vice versa, without passing through the denfities 7 and 8; because, in the abrupt passage, there tive argument.

would be two densities, 6 and 9, in the same instant. Boscovice The body must pass through all the intermediate den- System fities. This it may do quickly or flowly, but ftill it Philosophia must evidently pass through them all. The like may be said of all variable quantities; and thence we may conclude, that the law of continuity is universal.

But, in creation, is there not an inflance of an abrupt Objection passage from non-existence to existence? No, there is not; to this because before existence a being is nothing, and there. answered fore incapable of any state. In creation, a being does not pais from one state to another abruptly; it passes over no intermediate state: it begins to exist and to have a state, and existence is not divisible. Do we not, at least, allow of an abrupt passage from repulsive to attractive forces in our very theory itself? We do not. Our repulfive forces diminish, through all the intermediate magnitudes, down to nothing; through which, as a limit, they pass to attraction. In the building of a house or ship, neither of them is augmented abruptly; because the additions made to them are effected solely by a change of diffances between the parts of which they are composed; and all the intermediate distances are gone through. The like may be faid of many other such cases; and still the law of continuity remains firm and constant.

Let us now apply this doctrine to the case above Impossible mentioned of the collision of two bodies. We fay that lity of on the body B cannot pass from the velocity 6 to the ve. tact belocity 0 without passing through the velocities 6 and a tween by locity 9 without passing through the velocities 6 and 7; dies. because if it did, in the moment of contact of the two fuperficies it would have the velocities 6 and 9. Now a body cannot have two velocities at the same instant, For if it had two actual velocities at the same time, it would be in two different places at the fame time: if it had two different potential velocities or determinations to a certain velocity, it would be capable of being, after a given time, in two places at once-both which are impossible. It is therefore necessary that it go through the velocities 7 and 8, and through all the parts of them. What we have faid of the bodies A and B may be faid univerfally of all bodies. Therefore no two bodies in motion can come to immediate contact; but their velocities must undergo the successive necessary change before contact. And as the velocity to be extinguished may be increased beyond all limits, an adequate cause to effect this extinction must be admitted.

This naturally leads us to the interior repulfive forces Repulfive of our fystem. for the cause retarding the one body forces and accelerating the other must be a force, because by this we mean a determination to motion; and it muit be repulfive, because it acts from the body; and it must increase beyond all limits, seeing the velocity of the incurring bodies may be increased beyond all limits. It must likewise be mutual, because action and reaction are always equal, as may be proved by induction.

From these repulsive forces Boscovich deduces the in extendinextension of his atoms: for this repulsion being com-ed atoms mon to all matter, must cause a perfect simplicity in the first elements of body. If these elements were extended, and consequently compounded of particles of an inferior order, these particles might possibly be separated. and then they might meet, and an abrupt paffage from one velocity to another might take place, which we have excluded from nature by induction, and by a posi-

Besides this, by rejecting the extension of the tiof n of elements of matter, we get rid at once of all the difficulties arifing from con inued extention in body, which have always perplexed the philosophers, and have never been satisfactorily explained. If the elements of matter are extended, each of them may be divided in infinitum, and each part may still be divided in infinitum. Can this division be actually made by the power of God or not? Can there be one infinite in number greater than another? Can there be a compound without a simple of the same kind? These difficulties regard not space, which is no real being; but they would regard matter if it had continued extension. All these perplexities are removed by maintaining, as Boscovich does, that the first elements of bodies are perfectly simple, and therefore inextended (A).

> With regard to the exterior attractive forces of our fystem, there can be no question; seeing they constitute univerfal gravity, the effects of which we fee and feel every day. But between the interior repulfive and exterior attractive forces we must admit many transitions from repulsion to attraction, and from attraction back to repulsion, in infensible distances, which are indicated to us by cohefion, fermentation, evaporation, and other phenomena of nature. And thus we have given, in

short, Boscovich's proofs of his whole system.

III. This tystem has been well received by the learn. ed in Europe, and has contributed much to render its author famous; yet many objections against it have been proposed Some are startled at the rejection of all immediate contact between bodies; and indeed Boscovich is perhaps the first of mankind who advanced that opinion; but he allows that bodies approach fo near to one another, as to leave no fenfible distance between them: and his repulfive forces make the same impression on the nerves of our fenies as the folid bodies could do. And therefore this opinion of his, however new, is nowife contrary to the testimony of our senses. He only removes a prejudice which was before universal.

Some fay, that they cannot even form an idea of an inextended atom, and that Boscovich reduces all matter to nothing: but certainly extension is not necessary for the effence of a being, as must be allowed by all those who hold that spirits are inextended. Because all the bodies that fall under our fenses are extended, we are apt to look upon extension as effential to matter: but this error may be corrected by reflection, and an idea of an inextended atom may be formed, by confidering the nature of a mathematical point, which is the

limit of any two contiguous parts of a line.

Others again have faid, that if the elements of matter were void of extension, there would be no difference between body and spirit But the difference between body and spirit does not consist in the having or not having extension; but in this, that the atoms of

matter are endued with repulsive and attractive forces, Boscovich's which foirit has not; and spirit has a capacity of thought Sistem of and volition which bodies have not.

We may here observe, that among the ancients Zeno, and among the moderns Leibnitz, held, that the first principles of matter are inextended points. But both held this opinion with the inconfidency, that they maintained the continued extension of bodies, without ever being able to shew how continued extension could arise from inextended elements.

It has been objected likewise, that our repulsive and attractive forces are no better than the occult qualities of the Peripatetics. The like objection has been made to Newton's attraction: but the answer is easy. We observe the effects, and take notice of them: for them we must admit an adequate cause, without being able to determine, whether that cause is an immediate law of the Creator, or some mediate instrument that he makes use of for that purpose.

Some are unwilling to give up the idea of motion occasioned by immediate impulse: but can they show a good reason why some distance may not occasion motion as well as no distance? These are the principal objections that have been made against the Boscovichian

IV. Before we proceed to the explication of pheno-Olfervamena by means of our theory, we must advert, that in tions with the curve expressing this theory, the abscisses denote the curve. the distances between the atoms that are under confideration; the ordinates give the prefent force, and the area between any two of these ordinates gives the square of the velocity generated between them: the arches are either repulfive or attractive, according as they fall upon the fame fide with the afymptotic curve EG, or on the opposite side.

We must, in the next place, consider the passages from one fide of the axis to the other. Sometimes the passage is from repulsion to attraction, at other times from attraction to repulsion. The first are called limits Limits of of cohesion, because a particle removed from that limit cohesion, returns back to it; because if it is removed to a greater &c. distance it is attracted back, and if it is removed nearer it is repelled back The fecond are called limits of noncohesion; because a particle removed thence to a greater distance is repelled still further, and if removed nearer it is attracted still nearer. Of the first kind are E, I, N; of the fecond are G, L. Likewise, when the curve touches the axis, it may either be an attractive part of the curve, or a repullive part. These limits may be nearer one another, or farther away; and the limits of cohesion may be stronger or weaker, according as the forces near them are greater or lefs.

Bolcovich considers minutely the effects of these varieties of limits and forces; first with regard to two points, then with regard to three and four, demonstra-

(A) If a particle of matter is not extended, in what respect does it differ from a point of space? Says Boscovich, it is endowed with attractive and repulsive forces: What is this it before it is thus endowed? Does it then differ from a point of space? We can form no notion of any such difference. But a point of space, considered as an individual, is diftinguished from another individual only by its situation; it is therefore immoveable, but matter is moveable. Have these forces, then, which make matter an object of sense, any substratum, any thing in which they are inherent as qualities? What are the things which these qualities distinguish from each other as individuals?

Philefophy.

Befeovich's ting the great variety of forces that may arise from System of these various combinations, and shewing how from sim-Philosophy, ple atoms a great variety of bodies may be formed. He particularly proves, that, from the various position of

the atoms, they may either always repel or always at-Composi. tract other atoms, or do neither. Four atoms may tion of bo-form a pyramid, eight may form a cube, and so on, in regular or irregular figures. Particles of the lowest order may compose particles of a second order, these of a third, and so on. This he exemplifies by a library, in which the letters of the books should be composed of fmall points, placed fo near one another as that their distance could not be perceived without the help of a microscope. Here the letters will be composed of points, the words of letters, and all the variety of books on different subjects, and in different languages, would be composed of words. In like manner, he fays, his atoms may compose particles, these may compose others of different orders, of which may be formed various bodies, animal, vegetable, air, fire, water, earth, whole planets, central bodies, the whole universe.

The fystem But to be more particular, our author proceeds to apply his fystem to mechanics, and demonstrates, with his usual accuracy and originality, what regards the centre of gravity, action and reaction, the collision of bodies, the centre of equilibrium, and of oscillation. Of these subjects he treats in the second part of his Theoria; to which we must refer our learned readers, as

it cannot be eafily abridged.

In the third part of the same work he proceeds to account for the general properties of matter, beginning Impenetra- with impenetrability. This naturally flows from the interior repulfive forces, which prevent the compenetration of any two points. Besides, as the least part of space is divisible in infinitum, it is infinitely improbable that any two points should ever meet, seeing they have an infinite number of other lines in which they can move, besides the one that would join them. But an apparent compenetration might take place, if one body should meet another with so great a velocity as not to give time to the repulsive forces to exert their action. Thus an iron ball may pass swiftly near a strong magnet, without being fenfibly attracted by it, which it would be if it moved more flowly. Thus a ball from a gun passes through a piece of wood so quickly as to make only a passage for itself, without breaking the neighbouring parts, which it would do were its motion more flow. Of this kind of compenetration we have a refemblance in light passing through pellucid bo-

Cohefion has never been well accounted for by any philosopher before Boscovich. From his system it follows naturally, as we have feen in speaking of the limits of cohefion; for when two atoms are placed in a limit of that kind, they necessarily cohere more or less strongly, according as that limit is stronger or weaker. From the cohesion of the atoms arises the cohesion of compounded particles, and confequently of fensible bodies.

From the cohesion of particles arises the extension of bodies; because there must always be space between the particles. However, it is evident that this extension is not formed of a continuity of matter; though it may appear to be fo to our fenses, which cannot perceive the small intermediate distance between the parts of

fome bodies, and much less the distances between the Bosevie , fimple elements of which they are composed.

Extension of bodies involves figurability; because eve- Philosog ry extended body must be surrounded by some supersicies of a certain figure; but the superficies of bodies can never be accurately determined, upon account of Figur, the inequalities in all furfaces. We take, however, that figure for the true one which the body appears to come nearest. Thus we call the earth a globe, notwithstanding the hills and valleys that are on it.

Under the same figure, and of the same magnitude, there may be contained very different quantities of matter. Hence we come to the consideration of density. That body is most dense which contains in the same space the greatest number of atoms, and vice versa.

This denfity may be increased beyond any given li- Denlin. mits by the nearer approach of the atoms to one another. Hence a body of any given magnitude, however fmall, may come to be divifible beyond any given li-

Mobility, which is likewise reckoned among the ge- Mobil neral properties of body, is effential to our fystem, feeing an effential part of it confifts in forces, which are determinations to motion, at least in certain distances.

Universal gravity in sensible distances is likewise a Gravit branch of our theory. On which subject it may be obferved, that perhaps our curve, after it has extended beyond the sphere of the comets most distant from the fun, may depart from its asymptotical nature, and approach to the axis, interfect it, and pals to repulsion. This would effectually answer the objection made by some against Newton's attraction, when they allege, that, from his opinion, it would follow, that the fixed flars, and all matter, would be drawn together into one mass. If such a repulsion takes place, it may soon pass again into attraction, and form limits of cohelion; fo that our fun may be in such a limit with regard to the fixed stars, and our planetary system make only a small part of the whole universe. And this may suffice concerning the general properties of matter.

Let us now descend to some particular classes of bo. Fluid dies, of which some are fluid, others folid. The parts of fluid bodies are eafily separated, and eafily moved round one another, because they are spherical and very homogeneous; and hence their forces are directed more to their centres than to one another, and their motions through one another are less obstructed. Between the particles of fome of them there is very little attraction, as in fine fand or small grains of feed, which approach much to fluidity. The paticles of some others of them attract one another fenfibly, as do those of water, and still more those of mercury. This variety arises from the various combinations of the particles themfelves, of which we have already taken notice. But in air the particles repel one another very strongly; and hence comes that great rarefaction, when it is not compressed by an external force. Its particles must be placed in ample limits of repulsion.

Solid bodies are formed of parallelopipeds, fibres, and Solid of irregular figures. This occasions a greater cohefion than in fluids, and prevents the motion of the parts round one another; fo that when one part is moved all the rest follow. Of these bodies some are harder, whose particles are placed in limits which have flrong repul-

applied, to

account for

18 Cohelion,

Extension,

De wich's five arches within them; others are fofter, whose partithe limits of cohesion. They may even occupy less Boscovich's flexible, the particles of which are placed in limits that forhy have weak arches of repullion and attraction on each fide; and if those arches are short, the paticles may come to new limits of cohefion, and remain bent: but if the arches are longer, the former repulsion and attracelastition will continue to act, and bring back the body to its former position; nay, in doing this with an accelerated velocity, the parts will pass their former limits, and vibrate backwards and forwards, as may be feen in a bended spring. Thus elasticity is accounted for.

Viscous bodies stand in the middle between solid and Their particles have less cohesion than the first, and more than the second: they stick to other bodies by an attraction which their particles have from their composition. In like manner water itself sticks to some bodies, and is repelled by others. All which ariles from the different composition of the particles, which

gives a variety of respective forces.

efs,

Or niza-

What appears very wonderful in nature, is the composition of organic bodies. But if we consider that particles may be fo formed, that they may repel fome and attract others, the whole of vegetation, nutrition, and fecretion, may be understood, and follows from our fystem. And as one particle may attract another in one part only, and repel it in every other fituation, hence may be gathered the orderly fituation of the particles in many crystallizations. The great variety of repulfive and attractive forces, or limits of cohefion, of the position of atoms, and of combinations of particles, will account for all these phenomena.

The chemical operations, which are fo curious in themselves, and so uteful to society, are well explained by Boscovich's system, and serve as a confirmation of its truth. Of this we shall give some instances. When fome solide are thrown into some liquids, there happens to be a greater attraction between the particles of the folid and of the liquid than there is between the particles of the folid itself. Hence the particles of the folid are detached and furrounded by the fluid; this mixture retaining the form of globules, and therefore continuing to be fluid This is called folution. But when the folid particles are covered to a certain depth, the attractive forces cease on account of the different distances, and no more of the solid is detached. Then the fluid is faid to be faturated. If into this mixture another folid be put, the particles of which attract the fluid more firongly, and perhaps at greater diffances than the particles of the former; then the fluid will abandon the former and cleave to the latter, diffolving them, and the particles of the former will fall to the bottom in the form of powder, into which they had been reduced by the folution. This separation is called precipitation. Perhaps rain arifes from a precipitation of this kind, when the aqueous particles are left by the air, which is more strongly attracted by some other particles floating in the atmosphere.

Fluids of the same specific gravity are easily mixed; and even though the specific gravity be different, the particles of the one attract those of the other, in fuch a manner that they feem to form one fluid by a kind of folution Nay, it happens, that two fluids mixed toge-

SUPPL. VOL. I. Part I.

cles have those arches of repulsion weaker. Some are space than they did before, by being attracted into less System of distances between their parts. Philosophy.

Fermentation is a necessary consequence of our system. For when bodies, whose particles, by the variety of their composition, are endued with different forces, come to be mixed, there mult arise an agitation of the parts, and an ofcillation among them; fometimes greater, fometimes lefs, according to the nature of the particles. This agitation is stopped by the expulsion of some particles, by the intrusion of others into vacant spaces, and by the impression of external bodies; but always there is a change in what remains, because there is a new disposition of particles.

Fire consists in a violent fermentation of sulphure. Fire and fus ous matter, especially when it meets with the matter sion, &c. of light in any quantity. This fermentation agitates strongly the parts of other bodies, separates them from one another, and often throws them into a state of fufion; the cohefion between their parts being broken, and they being thrown into a circular motion. In this flate they may be often mixed together, fo as to form one body; they may be again separated by the action of the fame fire, which evaporates some of them sooner, fome later. Hence the art of fmelting metals.

When, in the agitation occasioned by fire, some of the particles are thrown out into an arch of repullion, they may fly off and evaporate. Sometimes the whole body may be thrown into a strong repulsion and volatilization, or a fudden explosion take place; when, before the particles are near an equilibrium, a small force may occasion a great change; as the foot of a bird may occasion the fall of a great rock, which was before almost detached from a mountain. In evaporation, the bodies that remain assume a particular figure, as all falts do; and this upon account of their particles having certain parts only that attract one another, and confequently occasion a particular disposition. All these chemical operations evidently prove that there are in nature repulfive and attractive forces between the particles of bodies at small distances; which greatly confirms our whole fystem.

Boscovich holds, that light is an effluvium, emitted Light. with great velocity from the luminous bodies by a strong repulsion. He explains all the most remarkable properties of this extraordinary matter according to his own principles, and that with great acuteness. On this subject it is observable, that Newton saw the necessity of admitting repulfive forces for the reflexion of light, which extend at some distance from the reflecting furface, and therefore refemble the repulfive forces of our

Our author gives likewife a probable explication of Electricity electricity, according to Franklin's ingenious hypothe-and magfis, and likewife of magnetism, deducing the whole of netism. the appearances from various attractions and repulfions. He supposes that fire and the electrical fluid differ only in this, that fire is in actual fermentation, and not to the electrical fluid.

Finally, he explains our bodily fensations, in which sensation. he agrees pretty much with other philosophers; excepting in this, that what they attribute to the immediate contact of bodies, or of certain particles emitted from ther form a folid, because their particles come to be in them, he ascribes to attractions and repulsions; which 0

System of our nerves, which is supposed to take place in the or-Philosophy, gans of fenfation, and to be thence communicated to

It is to be observed, that although Boscovich maintains, that the very first elements of matter are void of extension; yet he allows, that of these elements, combined in a certain manner, may be formed extended particles of various figures, the parts of which may be so coherent as to be inseparable by any power in na-Reconciliature. By these means the opinion of those philosophers, tion of this who are so fond of extended particles, may be in so far with other gratified. Nay, the Peripatetics may, if they pleafe, adopt Boscovich's inextended atoms for their Materia Prima without any inconfishency; and his repulsive and attractive forces may serve for their substantial forms. And as God can make impressions on our senses independently of the atoms, their absolute accidents may in some sense be admitted. Nor would some such extraordinary exertions of Divine Power favour idealism

in the ordinary course of nature.

But what is of more confequence, it is more than probable, that had Newton lived to be acquainted with the Boscovichian theory, he would have paid to it a very great regard. This we may conjecture from what he fays in his last question of optics; where, after having mentioned those things which might be explained by an attractive force, succeeded by a repullive one on a change of the distances, he adds, " And if all these things are fo, then all nature will be very fimple, and confishent with itself, effecting all the great motions of the heavenly bodies by the attraction of gravity, which is mutual between all those bodies, and almost all the less motions of its particles by another certain attractive and repulfive force, which is mutual between those particles." And a little after, treating of the elementary particles, he fays: " Now it feems that thefe elementary particles not only have in themselves the vis inertia, and those passive laws of motion which necessarily arise from that force, but that they likewise perpetually receive a motion from certain active principles; fuch as gravity, and the cause of fermentation, and of the cohesion of bodies. And I consider these principles, not as occult qualities, which are feigned to flow from the specific forms of things, but as universal laws of nature, by which the things themselves were formed. For that truly fuch principles exist, the phenomena of nature shew, although what may be their causes has not as yet been explained. To affirm that every species of things is endued with specific occult qualities, by which they have a certain power, is indeed to fay nothing; but to deduce two or three general principles of motion from the phenomena of nature, and then to explain how the properties and action of all corporeal things follow from those principles, this truly would be to have made a great advancement in philosophy, although the causes of those principles were not as yet known. Wherefore I do not hesitate to maintain the above said principles of motion, feeing they extend widely through all nature." From this passage we may safely conclude, that the great British philosopher would have been highly pleafed, had he feen all nature fo well explained by the one simple law of forces proposed by the Raguthe key of fan.

Boscovich's indeed are particularly fit for causing that motion in of his system, that he was wont to make use of the fol-Boscovich lowing comparison: When a letter has been written in System. occult characters, and we are endeavouring to decypher philosophi it, we make various suppositions of alphabets; and when we have found one according to which the whole letter comes to have a reasonable meaning, agreeable to all the circumstances of time, place, persons, and things, we can entertain no doubt of our having discovered the true key of the cypher-fo, faid he, my tyftem explains fo well all the phenomena to which it has been properly applied, that I must flatter myself that I have discovered the true key of nature.

The being accustomed to contemplate so deeply the Exidence universe and the materials of which it is composed, made of God. Boscovich see most clearly the evident necessity of admitting an all-powerful, intelligent, self-existent Being, for the creation of those materials, and for the arrangement of them into their present beautiful form. He was at a loss to find words strong enough to express his furprife, that there should be any man, not to say any one pretending to the name of philosopher, who could be fo deaf as not to hear the voice of nature loudly proclaiming its Author from all, even the least of its parts. He gives us his fentiments on this, the most important of all fubjects, in the appendix to his Theoria, in which

he treats of God and of the foul of man.

There, in the first place, he shows the absurdity of The wa their opinion, who maintain that this world may have cannot been the work of chance, the effect of a jumble of felf the effect existent, felf moving atoms; because chance is an empty chance; word without a real meaning. Whatever exists has its determinate cause, and can only be called fortuitous by us on account of our ignorance of that caule. Befides this, though the number of atoms composing this world is finite, yet their possible combinations are many times infinitely infinite: for they may be placed in infinite places of an infinite line; of these lines there is an infinite number in every plane, and of these planes there is an infinite number in space. Again, these points may have an infinite number of velocities in an infinite number of directions. From all this it is evident, that the combinations in which the points of matter may be, is in anite in a high degree, whereas duration can be infinite in only one dimension. Hence it is infinitely improbable that ever the present combination of things could come out by chance. And this is so much the more infinitely improbable, because the disorderly, chaotic combinations, are infinitely more than the regular ones. The whole of matter might roll about in a blind motion for a boundless eternity, without ever being capable to produce one fingle mushrom.

Moreover, had matter been in motion from all eternity, every atom would have described an infinite line, and then a part of that line would be affignable at an infinite distance from the point of space in which the atom is at present: but an infinite line can never be run over; therefore the atom could never have come to its present place; and therefore the supposition is absurd. Nothing successive can be eternal with a past eternity, though it can continue without end. God alone can be eternal and actually infinite; but his eternity and

infinity are beyond our comprehension.

Neither can the world have existed of itself in any Nor have thing like to its present form from all eternity; for exilted Boscovich himself was so fully convinced of the truth matter is perfectly indifferent to numberless states, and from et

Especially that of Newton.

Compari-

fon of this

fystem to

a cypher.

ovich's to its present state it must be determined. This present tem of state is perfectly incapable of determining itself, because this determination must be previous to its existence. It must be determined by the preceding state, which is alfo incapable of determining itself, and for its determination we must have recourse to the state before. Thus, though we go back to eternity, we shall still find a nullity of determination: now an infinite fum of nothing is nothing; and therefore as the present state of things could have no determination, it could not possibly exist.

It is therefore evident that there must be a Determiner extrinsic to the material world. This Determiner must have an infinite knowledge of all the possible combinations, and an infinite elective creative power to chuse and create freely the combination he pleased, in that point of eternity that he chose, with all the numberless circumstances that are agreeable to him.

And here what a vast field of contemplation is laid butes open to a philosophic mind! What a truly infinite ch apknowledge was requifite to foresee so many ends, and in the so many means requilite for obtaining those ends, as are contained in the creation! Let us confider light, for example, which was to be emitted for so many ages from fo many luminous bodies, with fo great velocity, fo as to penetrate fo many mediums with different degrees of reflectibility and refrangibility, with fo many other wonderful qualities; at the fame time, fo many bodies were to be perfectly fitted for reflecting this light in a certain manner, and the animal eye was to be so formed as to have a picture of visible objects painted on the bottom of it.-How many particular combinations were necessary for all this? What shall we say of the so many herbs, flowers, trees, and animal bodies, as there are on this our earth? All their kinds and species, all the feries of their individuals, all their parts and particles, were foreseen, intended, and contrived, by one act of the Divine Mind. Again, how wouderful are the heavenly bodies, of what furprifing magnitude, moving in the most beautiful order, at an immense distance from one another? To fay nothing of the numberless creatures that are beyond the reach of the best telescope, or below that of the microscope. He who restects ever so little on these things, must necessarily see the most evident proofs of an infinite power, wisdom, and providence; and he must be filled with admiration and awrul respect for the Creator and Ruler of the universe.

Nor are we unconcerned spectators of this grand scene. God has been pleased to make us enter deeply into his great plan of creation. He fingled us out among an infinite number of possible human beings, in order to call us into existence at a fixed period; and he has made a vast number of his creatures contribute to the formation of these wonderful machines, our bodies, as likewise to our nourishment, to our preservation, to our necessities, conveniences, and gratifications. Every moment that we exist we are enjoying a great number of benefits, expressly defigned for us by that Supreme Being. This evidently demands from us the highest degree of gratitude, love, and obedience.

Let us go a step still farther: Is it not very reasonable to suppose, that our God, who affords us so many instances of his beneficence towards us in the natural order, will also, out of compassion to our weakness and ignorance, have favoured us with a more full and explicit manisestation of himself, of our duties towards him,

and of his intentions concerning us? According to Bof- Bofhmen, covich and all true philosophers, reason itself alone, and Boswell. true philosophy, point out to us the probability at least of God's having given us a still better and surer guide, by whose direction we may attain to that perfect happiness which we naturally thirst after, and to which we must have been defigned by our Maker. This is probable from reason alone; and of this great fact we are ascertained by unquestionable authority.

BOSHMEN have been generally described as a distinct race of Hottentots, who are enemies to the paltoral life, (see Boshies-Men, Encycl.) This M Vaillant affirms to be a mistake; and we think he has completely proved that it is fo. "These infamous wretches (fays he) do not form a particular nation, nor are they a people who have had their origin in the places where they are now found. Boshmen is a name composed of two Dutch words, which fignity bufh men, or men of the woods; and it is under this appellation that the inhabitants of the Cape, and all the Dutch in general, whether in Africa or America, distinguish those malefactors or affasfins who defert from the colonies, in order to escape punishment. In a word, they are what in the British and French West India islands are called Maroon Negroes. These Boshmen, therefore, far from being a distinct species, are only a promiscuous assemblage of mulattoes, negroes, and mastizos, of every species, and fometimes of Hottentots and bafters (fee BASTER, Supplement), who all differing in colour, refemble each other in nothing but in villany. They are land pirates, who live without laws and without discipline, abandoned to the utmost mifery and despair; base deserters, who have no other refources but plundering and crimes. They retire to the steepest rocks and the most inaccessible caverns, and there they pass their lives. From these elevated places they command an extensive prospect over the furrounding plains, lie in wait for the unwary traveller and the scattered flocks, pour down upon them with the velocity of an arrow, and fuddenly falling upon the inhabitants and their cattle, flaughter them without diffinction. Loaded with booty, and whatever they can carry with them, they then repair to their gloomy caves, which they never quit till, like the lions, hunger again impels them to fresh massacres. But as treachery always marches with a trembling step, and as the prefence of one resolute person is sufficient to overawe whole troops of these banditti, they carefully shun those plantations where they are certain that the owners themselves refide. Artifice and cunning, the usual resources of timid fouls, are the only means which they employ, and the only guides that accompany them in their expeditions." - Vaillant's Travels into the Interior Parts of Africa.

BOSWELL (James), known to the learned world as the author of a life of Dr Johnson and of several other valuable works, was born, we believe, at Auchinleck in Ayrshire, in 1740. The family from which he sprung was ancient and honourable. At the time of his birth his father was a well employed lawyer at the Scotch bar; but was afterwards raifed to the dignity of Judge, and filled that important station with acknowledged learning, probity, and honour. His title was Lord Auchinleck, taken from his family inheritance; and he died in 1782: on which occasion Dr Johnson wrote an elegant and instructive letter to the subject of this brief not happen in vain, fince they gave rife to fuch falutary

"Your father's death had every circumstance that could enable you to bear it. It was at a mature age, and it was expected; and as his general life had been pious, his thoughts had, doubtless. for many years past, been turned upon eternity. That you did not find him sensible must doubtless grieve you; his disposition towards you was undoubtedly that of a kind, though not of a fond, father. Kindness, at least actual, is in our own power, but fondness is not; and if, by negligence or imprudence, you had extinguished his fondness, he could not at will rekindle it. Nothing then remained between you but mutual forgiveness of each other's faults, and mutual defire of each other's happiness."

The occasion of this family diffention is unknown to us. It might originate in the difference of their political principles, Mr Boswell being a zealous Fory, and his father, as he represents him, a rancorous Whig; or it may have arisen from the celebrated Douglas cause, which fet many friends at variance in Scotland, and in which Lord Auchinleck and his fon took opposite sides. The Judge gave his vote on the bench for the Duke of Hamilton; and the advocate (for Mr Boswell was then at the bar) was so keen a partizan of Douglas, that when the cause was finally decided by the House of Peers, he got possession of a Chinese gong, and, at the head of a number of young men and boys patrolled the ftreets of Edinburgh, and made a loud and exulting noise at the windows of his father's house, where there was no fymptom displayed of the general joy.

In 1762 Mr Boswell made his first journey to London; where, under the autpices of Dodsley the bookfeller, he published, "The Cub at Newmarket, a Tale." By the title of Cub he meant to characterize himself, as the reader will perceive in the following lines, which we shall give as a specimen of the poem:

> Lord Eglintoune, who loves, you know, A little dash of whim, or fo, By chance a curious CuB had got, On Scotia's mountains newly caught.

During his flay in London, Mr Boswell was introduced to Dr Johnson, with whom it is well known he continued to live in intimacy from that time till Johnfon's death in 1784; and this intimacy procured him the friendship of Burke, Goldsmith, Sir Joshua Reynolds, and many other men of eminence, who composed what was called The Literary Club. In the latter end of 1765 he became acquainted with General Paoli when on his travels; and after his return he published, in 1768 or 1769, his account of Cortica, with the "Journal of a Tour to that Island."

Of this work, which gained him fome distinction in the world, his great friend Johnson writes thus: "Your history is like all other histories, but your journal is in a very high degree curious and delightful. There is between the history and the journal that difference which there will always be found between notions borrowed from without and notions generated within. Your hiflory was copied from books; your journal rose out of your own experience and observation. You express images which operated strongly upon youself, and you

Boswell. memorial; of which we shall transcribe a passage that have impressed them with great force upon your read. Boswell. alludes to some slight domestic differences, which did ers. I know not whether I could name any narrative by which curiofity is better excited or better gratified."

> In 1770 Mr Boswell, who was then in good practice at the Scotch bar, married an amiable woman, by whom he had two fons and three daughters, who furvived him. In 1773 he was chosen a member of the LITERARY CLUB; and in the autumn of the same year he vilited the Hebrides in company with his illustrious triend Johnson; after whose death he published a very entertaining account of their tour, the places they faw, the characters with whom they converfed, and their own remarks on the different conversations. To many persons, both in England and Scotland, this book gave great offence, as it brought before the public the unguarded talk of private locial circles; but it furely furnished much entertainment, as it exhibited a more faithful picture of Hebridian manners than the British public had ever before feen.

In 1784, when Mr Fox's famous India bill was before Parliament, M1 Boswell published a "Letter to the People of Scotland on the Present State of the Nation;" in which he contends, that no charter would be fafe if that bill should pass into a law; and more than infinuates, that the principle of it was equally inimical to the liberties of the subject and to the prerogative of the king. Dr Johnson seems to have thought of that bill as he did; for having read the letter, he writes to the author his approbation of it in the following words: "I am very much of your opinion; and, like you, feel great indignation at the indecency with which the king is every day treated. Your paper contains very confiderable knowledge of the history and of the constitution, very properly produced and applied."

In 1785 Mr Boswell quitted the Scotch bar, and went to refide in London, where he continued till the day of his death. Having entered himself in one of the inns of court, and studied the English law, he became a barrister in England: but we have reason to believe that his practice there was not fo successful as it had been in his own country. He enjoyed, however, more completely than he could do in Edinburgh, the converfation of the great, the wife, the witty, and the good; and fuch conversation he always valued above wealth. He frequently vifited his native country, and especially Auchinleck, the feat of his ancestors; and foon after his return from one of those visits he was feized with a disorder which proved fatal, on Tuesday the 19th of May 1795.

Such were the principal events in the life of Mr Bofwell. Of his character, it would be difficult to fay much more than he has faid himself in his " Journal of a Tour to the Hebrides;" and which may, with some propriety, be copied here:

"I have given a sketch of Dr Johnson. My readers may wish to know a little of his fellow-traveller. Think, then, of a gentleman of ancient blood; the pride of which was his predominant passion. He was then in his 33d year, and had been about four years happily married. His inclination was to be a foldier; but his father, a respectable Judge, had pressed him into the profession of the law. He had travelled a good deal, and feen many varieties of human life. He had thought more than any body supposed, and had a pretty good

itock

fwell flock of general learning and knowledge. He had all Dr Johnson's principles, with some degree of relaxation. He had rather too little than too much prudence; and his imagination being lively, he often faid things of which the effect was very different from the intention. He resembled sometimes

"The best good man, with the worst-natur'd muse."

"He cannot deny himfelf the vanity of finishing with the encomium of Dr Johnson, whose triendly partiality to the companion of this tour represents him as one whose acuteness would help my inquiry, and whose gaiety of conversation, and civility of manners, are sufficient to counteract the inconveniences of travel, in countries less hospitable than we have passed."

Few of Mr Boswell's friends, we believe, could add much to this candid confession. His enemies, if he had any, might dwell upon his failings; but his failings were few, and injurious to no person. In his character good nature was predominant. He appeared to entertain fentiments of benevolence to all mankind, and to be incapable of intentionally injuring a human being. His conversation talents were always pleasing, and often fascinating. But can we wonder at this in him who, with a capacity to learn, had been the companion of Johnson for more than 20 years? His attachment to the Doctor for fo long a period was a meritorious perseverance in the defire of knowledge. To it the world is indebted for the most finished picture of an eminent man that ever was executed. We know there are objections to the mode of giving the life of Johnson. It has been thought that ignorance has been wantonly exposed, and the privacy of focial life endangered. We shall not onter deeply into this question. All that we can certainly affirm is, that the work has been read with avidity and pleafure; and that he who does not wish to read it again may be suspected to be deficient in taste and in

Mr Bofwell has been accused of vanity; but when this accufation is brought against him, it should not be forgotten that he enjoyed advantages which rendered that conspicuous in him from which no man can claim an exemption. We know not the man who would not have been vain to possess so much of Dr Johnson's conversation, and proud to give it to the world, in hopes that he who venerated Johnson would not be unthankful to his biographer. From the Doctor, however, he appeared to his friends to have imbibed a portion of mclancholy, of which indeed he complained himself during the last two or three years of his life; and he slew for relief where perhaps it is best to be found, to the society of the learned and the gay. Here, as he confesses, he had rather too little than too much prudence;" and, with more attachment to the activity of rural life, he might, probably, have lengthened his days. But as his "beliet in revelation was unshaken," and his religious impressions deep, and recurring frequently, let us hope that he has now attained that flate from which imperfection and calamity are alike excluded.

New South WALES in this Supplement.

BOUGUER (Peter), an eminent mathematician and mechanical philosopher, was born at Croisic, in Lower Bretagne, on the 10th of February 1698. His father John Bouguer, who was likewife a confiderable mathematician, was then professor royal of hydrography at Bouguer. that port; and under him young Bouguer studied mathematics, and the application of them to ship-building, almost from the period when he began to speak; fo that he was a proficient in these sciences before he had reached beyond the years of childhood. He was, liowever, removed from Croific to the Jesuits college at Vannes, where, at 13 years of age, he triumphed, in a public contest, over a professor of mathematics, who had advanced a mathematical proposition erroneously. Two years after this he loft his father, whom he was appointed to succeed in the office of hydrographer, after being publicly examined, and giving the most complete proof of his being duly qualified to fill the vacant chair. He was indeed qualified by prudence as well as by science; for however furprifing it may be, he filled it both with dignity and with abilities, though then not more than 15 years of age.

In the years 1727, 1729, and 1731, he gained the prizes successively proposed by the Academy of Sciences for essays on the best way of equipping ships with masts, on the best method of observing at sea the height of the stars, and on the most advantageous way of observing the declination of the magnetic needle or the variation of the compass. In 1729 he published an Optical Essay upon the Gradation of Light, in which he examined the intensity of light, and determined its degrees of diminution in passing through different pellucid mediums, and particularly in traverling the earth's atmosphere Of this effay, which was written upon a subject that till then had not attracted the attention of philosophers, the reader will find some account in the Encyclopadia Britan-

nica, under the title Optics, no 32, &c.

In 1730 Bouguer was removed from the port of Croisic to that of Havre. In 1731 he obtained, in the Academy of Sciences, the place of affociate geometrician, vacant by the promotion of Maupertuis to that of pensioner; and in 1735 he was promoted to the office of pensioner-astronomer. The fame year he was fent on the commission to South America, along with Mcsfrs Godin, Condamine, and Jeusseu, to determine the meafure of the degrees of the meridian, and the figure of the earth. In this painful and troublesome bufiness of ten years duration, chiefly among the lofty Cordelier mountains, our author, belides attending to the object of the voyage, made many scientific observations, viz. on the effect of the Cordeliers on the polarity of the magnetic needle; on the expansion and contraction of metals and other fubstances, by the fudden and alternate changes of heat and cold among those mountains; and on the refraction of the atmosphere from the tops of the fame, with the fingular phenomenon of the sudden increafe of the refraction, when the star can be observed below the line of the level. He likewise ascertained the laws of the denfity of the air at different heights, from observations made at different points of those enormous mountains; he discovered that the mountains have an effect upon a plummet, though he did not affign the quantity of that effect; he found out a method of effimating the errors committed by navigators in determiuing their route; gave a new construction of the log for measuring a ship's way; and made several other useful improvements. M. Bouguer made at different times fome important experiments on the famous reciprocation of the pendulum; he invented in 1747 the HELIO-

Bonguer. METER (fee that article Encycl.); and made many difcoveries relating to the intensity of light (for which see OPTICS-Index, Encycl.) His unremitting application to study undermined his health, and he died on the 15th

of August 1758, in the 61st year of his age.

Of his works which have been published, the chief are, 1. The Figure of the Earth, determined by the Observations made in South America, 1749, in 4to. 2. Treatife on Navigation and Pilotage, Paris, 1752, in 4to. This work has been abridged by M. La Caille, in one volume 8vo, 1768. 3. Treatife on Ships, their Construction and Motions, in 4to, 1756. 4. Optical Treatife on the Gradation of Light, first in 1729, then

a new edition in 1760, in 4to.

His papers that were inserted in the Memoirs of the Academy are very numerous and important: as, in the Memoirs for 1726, comparison of the sorce of the solar and lunar light with that of candles; 1731, observations on the curvilinear motion of bodies in mediums; 1732, upon the new curves called the lines of pursuit; 1733, to determine the species of conoid, to be conftructed upon a given base which is exposed to the shock of a fluid, fo that the impulse may be the least possible; determination of the orbit of comets; 1734, comparifon of the two laws which the earth and the other planets must observe in the figure which gravity causes them to take; on the curve lines proper to form the arches in domes; 1735, observations on the equinoxes; on the length of the pendulum; 1736, on the length of the pendulum in the torrid zone; on the manner of determining the figure of the earth by the measure of the degrees of latitude and longitude; 1739, on the astronomical refractions in the torrid zone; of servations on the lunar eclipse of the 8th September 1737, made at Quito; 1744, fhort account of the voyage to Peru by the members of the Royal Academy of Sciences, to measure the degrees of the meridian near the equator, and from thence to determine the figure of the earth; 1745, experiments made at Quito and divers other places in the torrid zone, on the expansion and contraction of metals by heat and cold; on the problem of the mailing of ships; 1746, treatise on ships, their structure and motions; on the impulse of fluids upon the fore parts of pyramidoids, having their base a trapezium; continuation of the short account given in 1744 of the voyage to Peru for measuring the earth; 1747, on a new construction of the log, and other inftruments for measuring the run of a ship; 1748, of the diameters of the larger planets; the new instrument called a heliometer, proper for determining them, with observations of the fun; observation of the eclipse of the moon the 8th of August 1748; 1749, fecond memoir on aftronomical refractions, obferved in the torrid zone, with remarks on the manner of constructing the tables of them; figure of the earth determined by MM. Bouguer and Condamine, with an abridgment of the expedition to Peru; 1750, observation of the lunar eclipse of the 13th December 1750; 1751, on the form of hodies most proper to turn about themselves, when they are pushed by one of their extiemities, or any other point; on the moon's parallax, with the estimation of the changes caused in the parallaxes by the figure of the earth; observation of the lunar eclipse the 2d of December 1751; 1752, on the operations made by seamen, called corrections; 1753, observation of the passage of Mercury over the sun the

6th of May 1753; on the dilatations of the air in the Bread, atmosphere; new treatife of navigation, containing the theory and practice of pilotage, or working of ships; 1754, operations, &c. for diffinguishing, among the different determinations of the degree of the meridian near Paris, that which ought to be preferred; on the direction which the string of a plummet takes; folution of the chief problems in the working of ships; 1755, on the apparent magnitude of objects; fecond memoir on the chief problems in the working of ships; 1757, account of the treatife on the working of ships; on the means of meafuring the light.

BREAD is so effential an article of food that every useful method of making it should be generally known. Much has accordingly been faid on that subject (Encycl.) under the titles Baking Barm, Bread, and YEAST; but, fince the last of these articles was published, we have feen, in Dr Townson's Travels in Hungary, a method of making bread at Debretzen; of which, as it may fometimes be adopted with advantage in this country, an account may, with propriety, be inferted here.

In the baking of this bread, a substitute is used for yeast, which is thus made: Two good handfuls of hops are boiled in four quarts of water: this is poured upon as much wheaten bran as can be well moistened by it: to this are added four or eve pounds of leaven; when this is only warm, the mass is well worked together to mix the different parts. This mass is then put in a warm place for 24 hours; and after that it is divided into small pieces, about the fize of a hen's egg, or a small orange, which are dried by being placed upon a board, and expoled to a dry air, but not to the fun; when dry, they are laid by for use, and may be kept half a year. This is the ferment; and it may be used in the following manner: For a baking of fix large loaves, fix good handfuls of these balls, broken into fragments, are taken and diffolved in feven or eight quarts of warm water. This is poured through a fieve into one end of the bread trough, and three quarts more of warm water are poured through the fieve after it, and what remains in the fieve is well pressed out. This liquor is mixed up with fo much flour as to form a mais of the fize of a large loaf: this is strewed over, with flour; the fieve, with its contents, is put upon it, and then the whole is covered up warm, and left till it has rifen enough, and its furface has begun to crack: this forms the leaven. Then 15 quarts of warm water, in which fix handfuls of falt have been diffolved, are poured through the fieve upon it, and the necessary quantity of flour is added, and mixed and kneaded with the leaven: this is covered up warm, and left for about an hour. It is then formed into loaves, which are kept in a warm room half an hour; and after that they are put in the oven, where they remain two or three hours, according to the fize. The great advantage of this ferment is, that it may be made in great quantities at a time, and kept for use. Might it not on this account be useful on board of ships, and likewise for armies when in the field?

Bread, in whatever way it is made, is a dear article; and it may be a defirable object to many of our readers to know at what price the baker can afford to fell it. This depends upon the price of wheat, the quantity of flour which the wheat may give, the loss at the mill, the expence of grinding, and the expence of baking.

Of the price of wheat we can fay nothing with pre- led before the police officers. They admitted the fact, Bread. of wheat will yield, exclusive of the loss in grinding and dreffing, 45% lb. of that kind of flour which is called feconds; which alone is used, through the greatest part of England, for bread, and which makes, indeed, the best of all bread, though not the whitest. A peck of this flour, weighing 14 lb. will take up between fix and feven pints of water, and give 18lb. of excellent bread; or a bushel of flour, weighing 56 lb. will yield 72 lb. of bread. The expence of baking a bushel of fuch flour is, in Effex and some other English counties, about ninepence; viz. yeaft, on an average, twopence; falt, before the late tax, one halfpenny; and baking, fixpence.

But seconds is not all that is got from wheat. A bushel of 60 lb. of wheat gives, besides 45% lb. of seconds, 13 lb. of offal, i. e. of pollards and bran; for the utmost loss in grinding and dressing a bushel of wheat should not exceed 1 pound 8 ounces. The millers, indeed, usually reckon on two pounds of loss; but we can fay, with the utmost confidence, that the actual loss is rather less than we have stated it. A correspondent of ours, on whose accuracy we can depend, weighed, in 1795, two bushels. Winchester measure, the one of white and the other of red wheat, and found the weight of them both to be 122 lb. This wheat was ground by his own fervants, and it yielded 1217 pounds of meal, so that there was here but $\frac{1}{2}$ lb. lost of two bushels, or of 122 lb. in grinding. He admits that he suffered the stones to turn too close, and that the loss should therefore have been somewhat greater. The meal was dreffed, as the wheat had been ground, under his own eye; and every possible precaution being taken to prevent his being deceived in the refult, he had of flour, or feconds, 931 lb. and of bran and pollard 251 lb.; fo that he loft, of two bushels, but 21 lb. both in grinding and dreffing. The offal, or bran and pollard, being dreffed in a bolting mill, yielded as follows:

6 lb. 0 oz. Sharps Fine pollard 5 8 Coarle pollard 8 Broad bran

8 Altogether 24 There was loft, therefore, in bolting, only one pound; and of the sharps, about three pounds, if sifted, would have been good flour. Indeed were the tharps and fine pollard to be added to the flour, the bread would, perhaps, be better, and more wholesome, than without fuch addition. From these data, which we believe to be very accurate, it will be eafy to calculate, if the price of wheat be given, what should be the price of flour per bushel and peck, the price of bread per pound, and the quantity of bread that should be sold for a shilling.

It is a fact, however, which should be attended to, that loaves are not always of the same weight, though made of equal quantities of the very same dough. This was fully afcertained fome years ago at Paris. On a violent complaint that the bread was not always of the same standard weight, the bakers of the city were cal-

cifion, because it varies according to the goodness or that loaves, baked at the same time, and in the same badness of the crop, and other circumstances; but a oven, were seldom, if ever, of the same weight; but bushel of Essex wheat, Winchester measure, may be they insisted, that they contained, each, the standard taken, on an average, as weighing 60 lb. Sixty pounds quantity of double and that the variety of weight among them must proceed from some cause, which they did not pretend to ascertain. The matter was referred to the Royal Academy of Sciences, which appointed one of its members to superintend. for some days, the whole process of baking. This being done it was found, that, of loaves baked in a large oven, those were always heaviest which occupied the centre of the oven, and that the bakers were innocent of the crime with which they were charged. The fact, we think, may eafily be accounted for. Even in an oven there mult be fome condensation of steam; and, from the very shape of the oven, the greatest quantity must be condensed towards the centre. Hence the loaves in the centre are necessarily wetter and heavier than those round the circumference, if the plain of the oven has been equally heated.

> BREAD of Rise might occasionally be of great use in many countries during a scarcity of wheat; but the method of making it is not generally known. It is indeed impossible to make bread of the flour of rice, which is harsh and dry like sand or ashes, by treating it in the manner in which wheat-flour is commonly treated; and therefore it has been proposed to mix it with an equal quantity of the flour of rye. But this method of uting the flour of rice is a very uncertain remedy in case of want; since we can have no rice-bread if we have not rye. We are taught, however, in the Journal des Sciences, des Lettres, et des Arts, how to make excellent bread from rice alone, by a method which the author of the memoir fays he learned from the natives of America.

According to this method of making the wished-for bread, the first thing to be done to the rice is, to reduce it to flour, by grinding it in a mill, or, if we have not a mill, it may be done in the following manner: Let a certain quantity of water be heated in a faucepan or caldron; when the water is near boiling, let the rice we mean to reduce into flour be thrown into it: the vessel is then to be taken off the fire, and the rice left to foak till the next morning. It will then be found at the bottom of the water, which is to be poured off, and the rice put to drain upon a table placed in an inclined position. When it is dry, it must be beat to powder, and passed through the finest sieve that can be procured.

When we have brought the rice into flour, we must take as much of it as may be thought necessary, and put it into the kneading-trough in which bread is generally made. At the same time we must heat some water in a faucepan or other veffel, and, having thrown into it some handfuls of rice, we must let them boil together for fome time: the quantity of rice must befuch as to render the water very thick and glutinous. When this glutinous matter is a little cooled, it must be poured upon the rice-flour, and the whole must be well kneaded together, adding thereto a little falt, and a proper quantity of leaven. We are then to cover the dough with warm cloths, and to let it stand that it may rife. During the fermentation, this paste (which, when kneaded, must have such a proportion of flour as

Bread, to render it pretty firm) becomes fo foft and liquid for home consumption and exportation. For this in- Brewing, Brew g. that it feems impossible it should be formed into bread. It is now to be treated as follows:

While the dough is rifing, the oven must be heated; and, when it is of a proper degree of heat, we must take a flewpan of tin, or copper tinned, to which is fixed a handle of tufficient length to reach to the end of the oven. A little water must be put into this stewpan, which must then be filled with the fermented paste, and covered with cabbage or any other large leaves or with a sheet of paper. When this is done, the stewpan is to be put into the oven, and pushed forward to the part where it is intended the bread shall be baked; heat of the oven acts upon the paste in such a way as to prevent its spreading, and keeps it in the form the flewpan has given it.

In this manner pure rice-bread may be made; it comes out of the oven of a fine yellow colour, like paftry which has yolk of eggs over it. It is as agreeable to the taste as to the fight; and may be made use of, like wheat bread, to put into broth, &c. It must, however, be observed, that it loses its goodness very much

as it becomes stale.

It may be here remarked, that the manner in which Indian corn is used in some countries, for making bread, can only produce (and does in fact produce) very bad dough, and of course very bad bread. To employ it advantageously, it should be treated like rice; and it may then be used, not only for making bread, but

BREWING is an art of vast importance, and has accordingly been explained in the Encyclopædia Britannica. A few improvements, however, have been made in the art, which, though not noticed in that Work, feem to be worthy of general attention, and, therefore, to deferve a place in this Supplement. The first, of which we shall give an account, is an invention of Mr WILLIAM KER of Kerfield, in the county of Tweedale, for the faving of hops, and, at the fame time, giving to the liquor, whether ale, beer, or porter,

a superior flavour and quality.

The steam which arises from the boiling copper is known to be strongly impregnated with the essential oil of the hops, in which their flavour confifts. Inflead, therefore, of allowing it to escape and evaporate, as it does in the common mode of brewing, Mr Ker contrives to preserve and condense it, by means of a winding-pipe fixed to the copper, fimilar to the worm of a still, or by a straight pipe passing through cold water, or any other cooling medium. The oil and water, thus obtained, are returned into the worts when boiled, or the oil, after being separated from the water, along with which it had been exhaled, is returned into the worts after they are boiled; and the watery part, which, after the oil is separated, still continues impregnated with the aromatic tafte and bitter of the hop, is returned into the next copper or boiling-veffel; and fo on from one copper or boiling-veffel into another. By this process a confiderable part of the hop and flavour, which is lost in the ordinary mode of brewing, is preferved: the flavour of the liquor is improved by the prefervation of the finer parts of the aromatic oil; and the ale and beer are better fecured from any tendency to acidity or putrefaction, and therefore must be fitter

vention, which is certainly simple, and we think rational, Mr Ker obtained a patent, dated March 4. 1788.

On the 4th of June 1700, Mr JOHN LONG of Long. wille, in the county of Dublin, Ireland. obtained a patent for an improvement in brewing, refembling, in one particular, this invention of Mr Ker's. To his invention, however, he gives the name of an entire new method, in all the effential parts, of brewing good malt-liquor; and therefore, as it comprehends the whole process of brewing, we shall lay it before our readers in

the words of its author.

" 1. For the better extracting from malt, place near a it must then be quickly turned upside down. The mash tun a shallow copper or other vessel that will readily heat; the curb of which to be on a level with the tun, and to contain from two to fix hogsheads, according to the dimension of the tun, more or less; and, at the lower end of the copper, have a cock from two to five inches diameter, more or less, to conduct the heated liquor from the copper into a tube which pafses down the external part of the tun, and enters it through an aperture about fix inches from the bottom; then forming two revolutions, more or less, through the body of the tun, and communicating its heat to the wort as it passes through the tube; and then, at a convenient distance from the place it first entered, it runs from the tun into a ciftern or tub, situate as near as convenient to the copper or heating veffel. In the tub or ciftern is to be placed a pump, for the purpose of conveying the cooler liquor back to the copper or heating-vessel again; there to receive the heat of 208 degrees, more or less (which it will require after the first half hour), and then convey it through the mashing tun as before, and in the same manner, as long as the working brewer or distiller may think necessary, to raise the mashing-tun to any degree of heat required. By adhering to the foregoing process, the first liquor may, with the greatest safety, be let upon the malt from 20 to 30 degrees lower than the present practice; by which means it operates with gentlenefs, opens and expands the male and raw corn, and prepares it for the reception of sharper or warmer liquor, so as to extract the whole of the faccharine quality from the malt and raw coin. By the foregoing method, the mashing tun, instead of losing its first heat (which it does by the present practice), continues to increase in heat every moment, by conveying the heated liquor through the tube into the tun; by which means, at the end of two hours, the working brewer or diffiller can have the tun brought to any degree of heat he shall think best suited to the different qualities of the malt or raw corn. Perfons who would wish to save expence, may heat their mashing-tun at the side or bottom by a large piece of metallic substance made fire-proof, and fixed therein; which, in some degree, will answer the end proposed, but with great trouble and delay.

" 2. To prevent the wort from receiving a dilagreeable flavour while in the under back, a tube must be placed at the cock of the mashing-tun, to receive the wort as it comes off, and convey it to a great ciftern or refrigeratory, which is supplied with a stream of water. The wort, passing through that medium in a spiral tube, soon loses that heat which so often proves prejudicial to the brewer and distiller in warm weather: then pass it from the tube into a vessel in which pumps

B ving, are placed, to return the worts into the copper for the done by the present practice; by which means I can Brideale purpose of boiling off. All vessels for receiving the cold wort must be placed lower than the source whence the wort comes.

"3. As the great object of long boiling the wort is remedied, by my invention of taking the extract from the hops in a separate manner from the worts, I boil my worts no longer than from 15 to 20 minutes; and, by purfuing that method, I fave much time and fuel,

and regulate my lengths accordingly.

" 4. I steep my hops, the preceding day to which they are to be used, in a copper or other vessel, with as much fluid, blood-warm, as will cover the liops, where it is to remain over a flow fire at least 14 hours, close covered; the copper at the tenth hour not to be of a greater heat than 175 degrees, continuing flow until the last hour. Then I bring the copper gradually to a simmer or slow boil; in which state I let it remain about 10 minutes, and then run off the fluid; and this I do at the same time the first wort is boiled off, that they may both pass together through the refrigeratory into the fermentation or working-tun. After the foregoing operation, I cover the hops again with other liquor, and bring the copper to boil as foon as convenient, and let it remain in that state a considerable time, until the fecond worts are boiled off: Then I pass the hop-fluid with the wort, the same as in the first instance; and, if there is a third wort, I boil my hops a third time with small worts, and pass it off as before; by which means I gradually obtain the whole of the essential oil and pleasing bitter from the hops. which is effectually preserved in the beer.

" 5. To cool worts. When the wort is boiled off, it is conducted from the cock of the copper or boiler into a tube of a proper dimension, which passes the wort from the cock to the large ciftern or refrigerato. ry, and there performs feveral revolutions, in a spiral manner, through the same tube; which is immersed in constant supply of cold water, where it loses the greatest part of its heat in a short time, and thence continues a ftraight course through the tube, a little elevated and of a fuitable length, placed in brick-work, until it meets a small refrigeratory, supplied with colder water from a refervoir made for that purpose at the head of the works; whence a continual stream runs on the surface of the tube down to the great refrigeratory, cooling the wort as it passes, in order to enable the working brewer or distiller to fend it into the backs or workingtuns at whatever degree of heat he shall think proper. There is no other difference between brewer and diffiller in this process, but that the distiller immediately passes the strong wort from the mashing-tun to the back, through the same machinery above inserted, and the tubes may be made of lead, or any other metallic substance.

"6. To enable me to brew in the warm fummer months, I fink my backs or working-tuns at least to a level with the ground, but if deeper the better, and cover them closely by an arclı made of bricks, or other materials, that will totally exclude the atmospheric air from them. I place them as near as possible to a spring or fand-drain, as their depth will naturally draw the water thence, which must be so contrived as to pass or flow round the backs or tuns. I then introduce a large tube, which passes through the tuns, and keeps the wort feveral degrees lower than can possibly be

SUPPL. VOL. I. Part I.

produce a complete fermentation even in the dog-days. Brind'ey.

" 7. In cold or frosty weather, if the tun and backs should lose the first heat, intended to carry it through the process by the foregoing method, you may convey a fupply of warm or boiling water by the tube, which passes through the body of the backs or tun, communicating its heat, which rifes to any degree the working brewer shall think proper: by pursuing this method, in the coldest season, I never want a fermentation."

We regret that we cannot with propriety flate to our readers, under this article, a fummary of Mr Richardson of Hull's Philosophical Principles of Brewing; for as the author has a new edition of his work in the press, it is our duty rather to refer to it, than to quote from a former edition, which contains not his last improvements. See FERMENTATION and MALT, in this Supplement.

BRIDEALE. See Scotale in this Supplement. BRIDGE. See that article (Encycl.), and ARCH in this Supplement. A wooden bridge, of large span, should be constructed on the principles explained under the title Roof (Encycl.) See also CRNTRE (Suppl.)

BRINDLEY (James), was born at Tunfled, in the parish of Wormhill, Derbyshire, in 1716. His father was a fmall freeholder, who diffipated his property in company and field amusements, and neglected his family. In confequence, young Brindley was left destitute of even the common rudiments of education, and till the age of 17 was cafually employed in rustic labours. At that period he bound himself apprentice to one Bennet, a mill-wright at Macclesfield, in Cheshire, where his mechanical genius prefently developed itself. The mafter being frequently absent, the apprentice was often left for weeks together to finish pieces of works concerning which he had received no instruction; and Bennet, on his return, was often greatly aftonished to fee improvements in various parts of mechanisin, of which he had no previous conception. It was not long before the millers discovered Brindley's merits, and preferred him in the execution of their orders to the mafter or any other workman. At the expiration of his fervitude, Bennet being grown into years, he took the management of the business upon himself, and by his skill and industry contributed to support his old master and his family in a comfortable manuer.

In process of time Brindley set up as a mill-wright on his own account; and by a number of new and ingenious contrivances greatly improved that branch of mechanics, and acquired a high reputation in the neighbourhood. His fame extending to a wider circle, he was employed, in 1752, to erect a water engine at Clifton, in Lancashire, for the purpose of draining some coal mines. Here he gave an effay of his abilities in a kind of work for which he was afterwards fo much diftinguished, driving a tunnel under ground through a rock nearly 600 yards in length, by which water was brought out of the Irwell for the purpose of turning a wheel fixed 30 feet below the furface of the earth. In 1755 he was employed to execute the larger wheels for a filk mill at Congleton; and another person, who was engaged to make other parts of the machinery, and to fuperintend the whole, proving incapable of completing the work, the business was entirely committed to Brindley; who not only executed the original plan in a maf-

Brindley. terly manner, but made the addition of many curious anti valuable improvements, as well in the construction of the engine itself, as in the method of making the wheels and pinions belonging to it. About this time, too, the mills for grinding flints in the Staffordshire potteries received various ufeful improvements from his

In the year 1756 lie undertook to erect a steam engine, upon a new plan, at Newcastle under-Line; and he was, for a time, very intent upon a variety of contrivances for improving this useful piece of mechanism. But from these designs he was, happily for the public, called away to take the lead in what the event has proved to be a national concern of capital importance—the projecting the fystem of canal navigation. The Duke of Bridgewater, who had formed his delign of carrying a canal from his coal-works at Worsley to Manchester, was induced by the reputation of Mr Brindley to confult him on the execution of it; and having the fagacity to perceive, and ftrength of mind to confide in, the original and commanding abilities of this felf taught genius, he committed to him the management of the arduous undertaking. The nature of this enterprise has already been described (Encycl. vol. IV. p 80); it is enough here to mention, that Mr Brindley, from the very first, adopted those leading principles, in the projecting of these works, which he ever after adhered to, and in which he has been imitated by all fucceeding artifts. To preferve as much as possible the level of his canals, and to avoid the mixture and interference of all natural streams, were objects at which he constantly aimed. To accomplish these, no labour or expence was spared; and his genius seemed to delight in overcoming all obflacles by the discovery of new and extraordinary contrivances.

The most experienced engineers upon former fystems were amazed and confounded at his projects of aqueduct bridges over navigable rivers, mounds across deep valleys, and subterraneous tunnels; nor could they believe in the practicability of some of these schemes till they saw them effected. In the execution, the ideas he followed were all his own; and the minutest, as well as the greatest, of the expedients he employed, bore the flamp of originality. Every man of genius is an enthusiast. Mr Brindley was an enthusiast in favour of the fuperiority of canal navigations above those of rivers; and this triumph of art over nature led him to view with a fort of contempt the winding stream, in which the lover of rural beauty fo much delights. This fentiment he is faid to have expressed in a striking manper at an examination before a committee of the House of Commons, when, on being asked, after having made conceived they were created for? he answered, "to feed navigable canals." A direct rivalry with the navigation of the Irwell and Mersey was the bold enterprize of his first great canal; and fince the success of that defign, it has become common, all over the kingdom, to tee canals accompanying, with infulting parallel, the courle of navigable rivers.

After the fuccessful execution of the Duke of Bridgewater's canal to the Mersey, Mr Brindley was employed in the revived defign of carrying a canal from that river to the Trent, through the counties of Chester and Stafford. This undertaking commenced in the year

1766; and from the great ideas it opened to the mind Brindler of its conductor, of a scheme of inland navigation which should connect all the internal parts of England with each other, and with the principal fea-ports, by means of branches from this main stem, he gave it the emphatical name of the grand trunk. In executing this, he was called upon to employ all the refources of his invention, on account of the inequality and various nature of the ground to be cut through: in particular, the hill of Harecastle, which was only to be passed by a tunnel of great length, bored through strata of different confiftency, and some of them mere quickfand, proved to be a most difficult, as well as expensive, obstacle, which, however, he completely surmounted. While this was carrying on, a branch from the grand trunk, to join the Severn near Bewdley, was committed to his management, and was finished in 1772. He alsoexecuted a canal from Droitwich to the Severn; and he planned the Coventry canal, and for some time superintended its execution; but on account of some difference in opinion he refigned that office. The Chefterfield canal was the last undertaking of the kind which he conducted, but he only lived to finish some miles of it. There was, however, fcarcely any defign of canalnavigation fet on foot in the kingdom, during the latter years of his life, in which he was not confulted, and the plan of which he did not either entirely form, or revise and improve. All these it is needless to enumerate; but, as an instance of the vastness of his ideas, it may be mentioned, that, on planning a canal from Liverpool to join that of the duke of Bridgewater at Runcorn, it was part of his intention to carry it, by an aqueduct bridge, across the Mersey, at Runcorn Gap, a place where a tide, sometimes rising sourteen feet, rushes with great rapidity through a fudden contraction of the channel. As a mechanic and engineer, he was likewife consulted on other occasions; as with respect to the draining of the low lands in different parts of Lincolnshire and the Isle of Ely, and to the cleansing of the docks of Liverpool from mud. He pointed out a method, which has been fuccefsfully practifed, of building fea-walls without mortar; and he was the author of a very ingenious improvement of the machine for drawing water out of mines by the contrivance of a lofing and a gaining bucket.

The intensity of application which all his various and complicated employments required, probably shortened his days; as the number of his undertakings, in some degree, impaired his usefulness. He fell into a kind chronic fever, which, after continuing some years, with little intermission, at length wore out his trame, and put a period to his life on September 27. 1772, in the some contemptuous remarks relative to rivers, what he , 56th year of his age. He died at Tunhurst, in Staffordshire, and was buried at New Chapel in the same

In appearance and manners, as well as in acquirement, Mr Brindley was a mere peafant. Unlettered, and rude of speech, it was easier for him to devise means for executing a defign than to communicate his ideas concerning it to others. Formed by nature for the profession he assumed, it was there alone that he was in his proper element; and fo occupied was his mind with his bufiness, that he was incapable of relaxing in any of the common amusements of life. As he had not the ideas of other men to affift him, whenever

alloy, a point of difficulty in contrivance occurred, it was his means refulting from them to give to his numerous fa- Briffot. custom to retire to his bed, where, in perfect folitude, he would lie for one, two, or three days, pondering the matter in his mind till the requilite expedient had prefented itself. This is that true inspiration which poets have almost exclusively arrogated to themselves, but which men of original genius in every walk are actuated by, when, from the operation of the mind acting upon itself, without the intrusion of foreign notions,

they create and invent. A remarkably retentive memory was one of the effential qualities which Mr Brindley brought to his mental operations. This enabled him to execute all the parts of the most complex machine in due order, without any help of models or drawings, provided he had once accurately fettled the whole plan in his mind. In his calculations of the powers of machines, he followed a plan peculiar to himself; but, indeed, the only one he could follow without instruction in the rules of art. He would work the question some time in his head, and then fet down the refult in figures. Then taking it up in this stage, he would again proceed by a mental operation to another result; and thus he would go on by stages till the whole was finished, only making use of figures to mark the feveral refults of his operations. But though, by the wonderful powers of native genius, he was thus enabled to get over his want of artificial method to a certain degree, yet there is no doubt that when his concerns became extremely complicated, with accounts of various kinds to keep, and calculations of all forts to form, he could not avoid that perplexity and embarrassment which a readiness in the processes carried on by pen and paper can alone obviate. His estimates of expence have generally proved wide of reality; and he seems to have been better qualified to be the contriver, than the manager, of a great design. His moral qualities were, however, highly respectable. He was far above envy and jealoufy, and freely communicated his improvements to persons capable of receiving and executing them; taking a liberal fatisfaction in forming a new generation of engineers able to proceed with the great plans in the fuccess of which he was so deeply interested. His integrity and regard to the advantage of his employers were unimpeachable. In fine, the name of Brindley will ever keep a place among that small number of mankind who form eras in the art or science to which they devote themselves, by a large and

durable extension of its limits. BRISSOT (J. P.), acted to conspicuous a part in the French revolution, that a fair detail of the principal events of his life would undoubtedly be acceptable to all our readers. A fair detail, however, of such a life, we believe it impossible at present to give; for characters like Briffot's are almost always misrepresented both by their friends and by their enemies; and till the troubles which they have excited, or in which they have been engaged, have long fubfided, the impartial truth is nowhere to be found.

In a fullome panegyric, under the denomination of The Life of J. P. Briffot, said to be written by himself, we are told, that he was born January 14. 1754; and that his father was a traiteur, or "the keeper of an eating-house," but in what place we are not informed. Our author, however, assures us, that the old man was in eafy circumstances, and that he employed all the

mily a good education. The subject of this memoir was intended for the bar; but not relishing the studies necessary to fit him for the profession of the law, or if we choose to believe him, having a mind too pure and upright for the study of chicane, he relinquished the purfuit after five years of drudgery!

To relieve his weariness and disgust, he applied himfelf, he fays, to literature and the iciences of the languages was above all others his favourite purfuit. Chance brought him acquainted with two Englishmen on their travels through France: he learned their language; and this circumstance, he tells us, decided his fate.

66 It was at the commencement of my passion for that language (continues he) that I made the metamorphofis of a diphthong in my name, which has fince been imputed to me as fo heinous a crime. Born the thirteenth child of my family, and the second of my brothers in it, I bore, for the sake of distinction, according to the custom of Beauce, the name of a village in which my father possessed fome landed property. This village was called Ouarville, and Ouarville became the name by which I was known in my own country. A fancy struck me that I would cast an English air upon my name; and accordingly I substituted, in the place of the French diphthong ou, the w of the English, which has precifely the fame found" For this puerile affectation, which was certainly not criminal, he justifies himself by the example of the literati of the 16th and 17th centuries, who made no scruple of Grecifing and Latinifing their appellatives.

Having profecuted his Itudies for two years, he had an application from the English proprietor of a poper then much in circulation, and intitled Le Courier de l'Europe. This man having drawn upon himself an attack from government, felt and yielded to the necessity of printing his paper at Boulogne fur-mer. It was his wish to render it interesting to the French in the department of miscellaneous intelligence; which he therefore wished to submit to the superintendency and arrangement of Briffot, who represents himself as for some moments hesitating. The profession of a journalist, subject to a licenter, was repugnant to his principles; yet it secured his independence, and put into his power the means of profecuting an investigation of constitutions and of the sciences. After some ridiculous reasoning from the original stations of Bayle, Poslel, and Rousseau, he at last accepted of the employment, and became enamoured of it, "because (fays he) it enabled me to serve talents and virtue, and, as it were, to inoculate the French with the principles of the English constitution.

This employment, however, did not last for any length of time. The plan of the proprietor of the Courier was overthrown by administration, and Brisfot quitted Boulogne to return to his first studies. Having informed us of this fact, he makes an extravagant pretence to unfullied virtue, and calls upon the inhabitants of the city which he had left to bear witness, not only that he had no vices, but that he had not even the feeds of any one of the vices which his adverfaries, it reems, had laid to his charge.

"Doubtless (says he), too eager to publish my ideas, I conceived that the proper moment had arrived, and I felt an inclination to commence with an important work.

Revelting.

Briffot. Revolting, from the very instant of my beginning to re- he constantly cultivated with ardour; but acknowledges Briffot. protested, that thenceforward I would consecrate my whole life to their extirpation. Religious tyranny had taire, of Diderot, and of D'Alembert. It became neceffary to attack the fecond;" and this was a task which the vanity of Briffot led him to confider as referved for him.

What Voltaire and his friends meant by religious tyranny, and how they conducted their attacks against it, are matters, alas! too well known to all Europe; and as our author chose these philosophers for his guides, we might infer, without much degree of miftake, what he understood by political tyranny, and by what means he meditated its extirpation. But he has not left us

to make this discovery by inference.

"It became necessary (fays he) to break in pieces the political idol, which, under the name of monarchy, practifed the most violent despotism; but to attack it openly, was to expose the affailant without the poffibility of ferving mankind. It was by a fide blow that it was to be wounded most effectually;" and therefore he resolved to begin his operations by attacking some of those abuses which might be reformed without apparent-

ly shaking the authority of the prince.

Our readers, at least the sober part of them, will probably think, that this mode of attack is not peculiar to Brissot, but that it has been practised, or attempted to be put in practice, by aspiring demagogues in all ages and countries, who have uniformly begun their career of innovation by exciting the public mind against those abuses in government, of which the existence cannot wholly be denied. The subject to which our author thought fit to call the attention of his countrymen, was the criminal jurisprudence: a subject, says he, which, with the exception of fome particulars that had been fuccessfully investigated by Beccaria and Servan, no writer had thoroughly confidered in a philosophical point of view. Thinking himself fully equal to this task, he drew up a general plan; and in the year 1780 publish ed his Theory of Criminal Laws, in two vols 8vo. This work, favourably received by foreigners, applauded by fome journalists, and pulled to pieces by others, procured him the friendship of the warmest advocates for human liberty, in whose opinion the defects of his plan were highly pardonable, on account of the energy conspicuous in his remarks. This publication was foon followed by two discourses which gained the prize in 1782 at the academy of Chalons-fur-Marne; the one upon the reform of the criminal laws, and the other on the reparation due to innocent persons unjustly accused.

It is natural to suppose that the government beheld with an evil eye thefe writings, which, under pretext of dragging into light the abules of the criminal laws, infinuated dangerous principles on the nature of govern-

ment in general.

His next work was intitled, A Philosophical Library of the Criminal Laws, in 10 vols; the true object of which was to differinate in France those principles of liberty which guided the English and the Americans in framing and expounding their laws.

But the study of legislation and politics had not entirely drawn him off from that of other sciences; such as chemistry, physics, anatomy, theology, &c. These

flect, against religious and political tyranny, I solemnly that in each he met with obscurities, and that in every quarter truth escaped from his researches. He therefore fat down to investigate the nature of truth, and fallen under the redoubled strokes of Rousseau, of Vol- the proper method of attaining to it in every department of research; and the result of his labours was a kind of novum organum, by which he feems to have expected that Bacon's work would be buried in oblivion; and to this important volume he gave the title of Concerning Truth; or, Thoughts on the Means of attaining Truth in all the Branches of Human Knowledge. This volume was meant as nothing more than the introduction to a greater work, in which he proposed to investigate what is certain in knowledge and what doubtful. and then to strike the balance of the account.

He was prevented, however, from completing his plan, which he regrets exceedingly; for, as he affirms, with becoming modesty, his work would certainly have amended its readers! But the French government happened to think otherwise; his aim, which, he fays, was to lead mankind to reflect on their rights, was perceived, and he was accused to the minister as a seditious writer. The career of genius was hopped by the dread of the Bastile; and he was obliged to take refuge in London. There it was his wish to create a universal confederation of the friends of liberty and truth, and to establish a centre of correspondence and union with the learned and the politicians of Europe. This dark defign, however, was frustrated by the treachery, as it would appear, of his affociates, who had bound themselves, he fays, by the most facred oaths, to assist him, and had offered to

fign articles even with their own blood.

Finding himself unable to proceed directly to the object which he had in view, he resolved to enlighten his. countrymen gradually, and to begin with exciting their love and admiration of the English constitution. That constitution, which he had investigated on the spot, appeared to him a model for those societies which were desirous of changing their form of government. It was but little known, he fays, in France (the work of De Lolme being at that time only in the hands of the learned); and to make it known was to make it beloved, was to render it defired. But the French ministers stood upon their guard, and it became necessary to deceive them. He refolved therefore to bring forward a journal, written actually in London, and professing to contain only a description of the sciences and arts of England, whilft the greater part of it was to be occupied in reality by an investigation of the English constitution.

After many difficulties, the ministry granted a privilege for this journal, being published in London, to be reprinted in Paris; and it first appeared in 1784. " In the twelve numbers which have been published (fays the author), the friends of liberty must have perceived, that if, on the one fide, I endeavoured to inculcate more just ideas than had hitherto been entertained concerning this celebrated island; fo, on the other, I resolutely. made my advances toward that important end which has perpetually prefided over all my labours, the universal

emancipation of men."

His affairs calling him at this time to Paris, he was arrested and conveyed to the Bastile on the 12th of July 1784. In this conduct of the government we cannot perceive any thing very tyrannical or arbitrary. fince he confesses, that, in the 16th page of the first

fot. number of his Journal, he had fuffered the fecret and favourite aim, which always guided his pen, to become discernible. He was, however, discharged from prison on the 5th of September, and returned with increased

zeal to his former employments.

"This perfecution (fays he), far from extinguishing the ardour of my wishes to inculcate the principles of freedom, ferved only to inflame it the more." Accordingly, in 1785, he published two letters to the Emperor Joseph II. concerning the right of emigration, and the right of people to revolt. The first of these letters, suppressed by the police, was occasioned by what the author calls the ridiculous and barbarous edict against emigration; and the second by the punishment of Horiab the chief of the Walachian infurgents. In this last letter he lays it down as a maxim, that all people under fuch a government as that of the Walachians, have from nature a facred right to revolt, a right which they can and ought to exercise. In the same spirit he brought out, in 1786, his Philosophical Letters on the History of England, in 2 vols, and A Critical Examination of the Travels of the Marquis de Chatelleux in North America.

The French revolution appearing to him extremely diftant, notwithstanding all his efforts to hasten it, he resolved to leave France for the purpose of settling in America. His project received the approbation of feveral, whose fentiments were congenial with his own. But as it was thought imprudent to transport numerous families to a country fo far off, without thoroughly knowing it, Briffot was engaged to proceed thither, to examine the different places, to observe the inhabitants, and to discover where and in what manner the establishment they had proposed might be most advantageously fixed. He had some time before instituted a society at Paris for accomplishing the abolition of the negro trade, and for foftening the condition of the flaves. At the period of his departure, this fociety confifted of a confiderable number of diftinguished members, and he was commissioned to carry the first fruits of their labours to America. His stay there, however, was not so long as he was defirous of making it. In the beginning of 1789 he was recalled by the news of the French revolution, which he conceived might probably produce a change in his own measures and in those of his friends. This idea, added to other circumstances, accelerated his return. The fire had blazed forth in his native country. " Hope (fays he) animated every heart; the most distinguished champions had engaged in the contest; I too became desirous to break a lance, and I published my Plan of Conduct for the Deputies of the People."

This, and other works of a fimilar kind, of which he loudly boasts the merits, raised him high in the favour of the republican part of the nation, and he became prefident of his diffrict; where he acted, according to his own account, with great uprightness in the municipality in the first committee of enquiries, and as an elector. At last he became a member, first of the National Affembly, and, after its dissolution, of the Sanguinary Convention; and by some means or other got to be the leader of a party called sometimes the Girondists, and sometimes the Brissotines. From that period the principal events of his life were involved with the puban account in the Encyclopadia under the title REVO- Brown. LUTION (fee that article, no 101-182.) The Girondist faction was denounced by the Mountain, and Brisfot inffered by the guillotine on the 30th of November 1793. He fell indeed by a very unjust sentence; but his fall was the natural consequence of that anarchical tyranny under which no man had contributed more than he to subject his native country.

BROWN (Dr John), author of the Elementa Medicine, &c. was born in the village of Dunse, or, as some fay, Lintlaws, in the county of Berwick, in the year which, though well known in Germany, were in France 1735 6. His parents were of mean condition, but much respected in the neighbourhood for the integrity of their lives. His father gained his livelihood in the humble capacity of a day-labourer; while his mother contributed her share towards the support of the fami-

ly by the profits arising from a milch cow

Such were the persons who, in an obscure part of the country, gave birth to a fon destined, at a future period, to make a diftinguished figure in the republic of letters; and from whom originated a system of the animal economy, which, whatever be its real merits, has. undoubtedly produced a confiderable revolution in the

practice of medicine.

At the age of three or four years, young Brown wasput to a reading school in Dunse, which he himself commemorates as the place rather of his education than of his nativity. Here, under the tuition of an old woman, he very early began to exhibit marks of that ftrength of mind for which he was afterwards fo eminently distinguished. In the short period of a year he became able to read with facility any part of the Bible, and acquired over his class-fellows that superiority which he ever after maintained both at school and college.

It was almost immediately after his entrance into this fchool, that his infatiable defire of reading commenced; and to unremitting was his application, that he is faid never to have been found, even at those hours which children much more advanced in life devote to amuse-

ment, without a book in his hand.

While he was making this rapid progress in the rudiments of literature, he fuffered what must have appeared to be a very heavy loss in the death of his father; but his mother foon afterwards married a worthy man of the same name, whose care and attention supplied the place of a father to her fon. This man being a weaver, defigned to educate his fon-in law to the same business, and began to instruct him in his art when he was about nine years of age: but the tafte which young Brown had already acquired for letters, made him look. with diffust on the infipid employment of a weaver. His step-father was no tyrant, and his mother was affectionate. They were both proud of the talents which at fo early a period of life had appeared in their fon, and they felt no inclination to struggle with the invincible averfion which he expressed to the business for which they intended him.

Another circumstance however, contributed in no fmall degree to make them recal their original refolution They were both of that feet of religionists which in Scotland are called Seceders (fee Seceders, Encycl.); and it was fuggested to them by some persons of their own perfuafion, who had remarked the uncommon abilities of the boy, that he might one day prove an able he transactions of the nation, of which we have given support and promoter of their tenets as a preacher. He

scioes.

from the buliness to which he had conceived such a distaste, and sent to the grammar-school of Dunse, which was taught at that time by a gentleman of the name of Cruickshank, eminent for his grammatical knowledge. Here he appears to have frent fome years with uncommon advantage and happiness; during which he was esteemed by all the country round as a kind of prodigy. Like Johnson, and many other men of the highest celebrity, he united in the same person uncommon powers of mind, with no less strength of body, as indeed his appearance indicated; and in his youth he infured his own personal importance among his schoolfellows, by excelling them not less in athletic exercises than in the tasks prescribed by their master. He was particularly fond, when a boy, of practifing the pugiliftic art; and indeed until the last period of his life he was observed by his friends always to view an exhibition of that kind with peculiar relish. He also prided himself much in being a flout walker; and mentions his having, in one day, accomplished, when but fifteen years of age, a journey of fifty miles between Berwick upon-Tweed and Morpeth in Northumberland. When farther advanced in life, he travelled on foot from four in the afternoon of one day to two in the afternoon of next day, with the fhort interval of one hour's reft! But as one of his biographers very justly observes, "we have feen that he could make a more rational use of his strength than merely to stake it against time and Dr Beda fpace **

His early years while at school were marked by the most rigid attachment to his sect. So strict indeed were his religious fentiments, if a boy of ten or eleven can be faid to have any fentiments deferving to be called religious, that he would have conceived the holding of any communion with the chablished church as a kind of profanation. An event, however, happened, some time between the eleventh and thirteenth years of his age, which produced a total and unexpected revolution in his religious opinions. At a meeting of the provincial fynod of Merie and Teviotdale, he was prevailed upon, though not without manifesting much reluctance, to accompany a party of his school fellows to the parish church of Dunle. The consequence of this transgreffion, as he had dreaded, was an immediate fummons to appear before the fession of the Seceding congregation; to which, through pride, not choosing to attend, in order to preclude a formal expulsion, he voluntarily abjured their tenets, and openly avowed his apostacy to the

All changes in religion which are not the confequence of candid investigation are dangerous. He who leaves one fect he knows not why, will quickly abandon, with as little reason, that to which in a fit of passion he had halfily joined himself. From the moment of his quitting the communion of the Seceders, Brown's religious ardour suffered a gradual abatement; and though, to please his mother, he continued to prosecute his studies with a view to the office of a clergyman in the church of Scotland, his opinions became daily more and more lax, and his life of course less and less regular. It was, however, a confiderable time before he admitted, in their full extent, those principles of irreligion which he afterwards avowed; for upon his first perusing the Ef-

Brown. was accordingly, much to his fatisfaction, taken away cooled, he expressed great indignation at their danger. Brown ous tendency.

At the age of twelve years he had been employed by Mr Cruickshank as a kind of usher in the school of Dunse; and that gentleman having declared that his knowledge of the Latin language was equal to his own, his fame as a scholar was so spread over the country, that at the age of thirteen he was entrufted with the education of a gentleman's fon in the neighbourhood, when he quitted the school and his beloved matter. In his new situation, however, he remained not long. Dr Beddoes conjectures, that to the stiffness of pedantry he added the fourness of a bigot, and was therefore a disagreeable inmate of the family. That a boy of thirteen, proud of his talents, and prouder of his learning, should have the fliffness of a pedant, is indeed extremely probable; it was the natural consequence of the praise with which he had been honoured by Mr Cruickshank: but there is reason to believe that of his original bigotry few traces now remained. The real cause of his dismission from the family, we are affured, was his pride; and as it must have been the pride of parts, it confirms the first part of Dr Beddoes's conjecture.

It feems he was much displeased that, when company were at dinner, he was not defired to remain after the cloth was removed; and yet if he was then only thirteen years of age, it is not easy to conceive for what purpose he should have staid. He could not possibly know much of the world, or of any thing likely to employ the conversation of country-gentlemen; and we cannot help thinking, that the mafter of the house would have treated his guests with rudeness had he detained among them a raw boy to liften to every unguarded expression which might escape them over their wine. It would appear, however, that he was not unwilling to give the tutor of his fon an opportunity of ditplaying his abilities, when fuch subjects were introduced as he knew him to have studied; for a dispute having arisen, one day after Brown had retired to his own room, concerning the decrees of Providence, he fent to request his opinions on that abstruse subject. By the messenger Brown returned a verbal answer, that "the decrees of Providence are very unjust, for having made blockheads lairds."

Mr Cruickshank had some time before requested him to return to the fituation which he had formerly held in the school of Dunse; and we cannot wonder that, immediately after making this infolent answer, he found it convenient to comply with his request. He was now about fifteen, and he continued in the school till the 20th year of his age; during which time, from the constant habit of teaching the Latin and Greek languages, he acquired a wonderful facility in reading both these languages, and in writing the former, though he wrote not with tafte.

About this time it occurred to him that he might turn his claffical acquirements to more account, by becoming a private teacher of languages in Edinburgh. To that city he accordingly repaired, where, while he obtained a livelihood as a teacher, he proposed at the fame time to purfue his theological studies at the univerfity. But an accident happened to him here which made him altogether change the plan he had come upon; and the death of his mother, after a refidence of some time in fays of Mr. Hume, though his own zeal was then much. Edinburgh, abfolved him, as he thought, from the promife

brown, which he had made to her of appearing one day in the pulpit. Shortly after an unfuccessful competition for one of the chairs then vacant in the high-school, an application was made to a friend of his for a proper perfon to turn a medical thesis into Latin. Brown was recommended. He was limited to a certain time; within which it appeared scarce practicable to perform the talk. He accomplished it, however, and in such a style of grammatical correctness and purity as far exceeded the general run of such productions. On this being remarked to him by his friends, he observed, "that he now knew his strength, and was ambitious of riding in his carriage as a physician." He therefore determined to apply himself with ardonr to the study of medicine, to which this accidental circumstance alone directed his attention. Accordingly, at the commencement of the next winter session, he addressed a Latin letter to each of the medical professors, and by them was presented with tickets of admittance to their feveral classes.

From fuch a favourable beginning, being of a very fanguine disposition, he conceived the most flattering expectations of his future success; and indeed for some time he feems to have lived in affluent circumstances. His attainments were fo various, and in fuch request in Edinburgh, that as a fingle man he could fcarcely fail to gain a competent living; for during the last five years of his residence under Mr Cruickshank, to a thorough acquaintance with ancient history, he had added a very confiderable knowledge of mathematics; in which, among other branches of science, he never had any objection to give instructions. In the acquisition of that variety of knowledge which he possessed, he was greatly affifted by a most tenacious memory; to the retentivenefs of which an old school-sellow bears testimony, by affirming, that " after once reading over the lesson, confifting of two octavo pages in Latin, he would lay afide the book, and prelect the whole over without mistaking a fingle word'

Brown, already in eafy circumstances for an individual, faw, or thought he faw, in the establishment of a boarding:house for students a resource which would enable him to maintain a family; and in expectation of realifing this prospect, he married, in 1765, the daughter of a respectable tradesman in Edinburgh. The distinguished attention at that time paid him by Dr Cullen, in whose family he had become a necessary person, contributed in all probability to strengthen his hopes that his house would be filled with proper boarders through the Doctor's recommendation. His fuccess in this way for fome time answered his most fanguine expectations; and his circumstances at one period were so flourishing, that he is faid to have kept a one-horse

It was, perhaps, the greatest misfortune that could have befallen Brown, that he possessed, in a high degree, those talents which make a man's company fought after by the gay and the diffipated: He was capa-ble of "fetting the table in a roar." We need not therefore wonder at his frequently neglecting more necessary pursuits to enjoy the conviviality of the numerous friends who courted his company; or that drinking and diffipation became habitual to him. He was as deficient in point of prudence as he excelled in genius. His house was filled with respectable boarders; but as he lived too splendidly for an income at best but precarious, he became gradually involved in debt, and his into Latin all the terms used in malonry.

affairs were still more embarrassed by the burden of a nu- Brown, merous family. Soon after he began to be involved in these difficulties, he suffered an additional loss in being deprived of the patronage of Dr Cullen, in confequence of a difagreement that had taken place between them. This enmity, which had for some time before secretly fubfifted, probably from mutual jealoufy. was at length excited into an open rupture; first, by Dr Cullen's not exerting his interest in procuring for Brown the theoretical chair of medicine, then vacant in consequence either of the death or refignation of Dr Alexander Monro Drummond; and, fecondly, by his rejecting, some time after, Brown's petition for admittance into the Edinburgh Philosophical Society.

In 1776 Brown was elected prefident of the Medical Society; and the same honour was again conferred on him in 1780. He was led on, in the gradual manner he himself describes in his masterly preface to the Elementa Medicina, to the discovery of his new doctrine; which, on dropping all correspondence with his former friend and benefactor, he now, for the first time, began to illustrate in a course of public lectures; and in these he disolayed equal ingenuity and philosophical profun-Much about the time of which we now speak, he published the first edition of the Elementa Medicina; a work which certainly proves its author to have been a man of uncommon genius and originality of thought. The circumstances in which this work was composed reslect great honour on his abilities. He never retired to his study; but, totally absorbed in his own ideas. wrote with the greatest tranquillity amidst the noise of ten children, occasionally settling their childish differences.

In the year 1779, though he had studied medicine ten or twelve years at the univerfity of Edinburgh, he was prevailed upon by his friends to take a degree at St Andrews, where he gave a confpicuous proof of his facility in Latin composition. He wrote a thesis, or inaugural differtation, in the tavern while the cloth was laying for dinner; and one of his companions, who was finging befide him, having uttered a false note, or sung out of time, Mr Brown, in the middle of his writing, stopped to shew him how the fong ought to be fung, and then instantly proceeded in his thesis.

His family having now become fo numerous as to render keeping a boarding houle inconvenient, he had already for tome time given it up, and depended for support entirely on his practice as a physician and his public lectures. At this time, the disputes between the Cullenians and the Brunonians (as the young men now styled themselves) were carried on with such acrimony on both fides, in the different focieties, that it was not unufual for them to terminate in duels; and there exists at this day, on the records of the Medical Society, a law which it was thought expedient to enact, by which a member who challenges another for any thing faid in public debate incurs the penalty of expulsion.

Observing the students of medicine frequently to feek initiation into the mysteries of free-maloney, Dr Brown thought their youthful curiofity afforded him a chance of profelytes. In 1784, he instituted a meeting of that fraternity, and intitled it the Lodge of the Roman Eagle. The bufiness was conducted in the Latin language, which he spoke with the same sluency as Scotch; and he displayed much ingenuity in turning

Brown.

of the faculty were fuch that he obstinately avoided meeting them even in confultation, we may conclude that his own private practice was but limited. His friends affirmed, perhaps without sufficient proof, that cabals were formed against him, and every advantage taken of the errors he was led to commit by his own imprudence. After a long feries of struggles, therefore, hoping to meet with that encouragement among the English of which he had been disappointed in his own country, he put in practice a plan upon which he had long meditated, and removed in 1786 with part of his family to London. Immediately on his arrival, an incident befel him, which Dr Beddoes fays he has heard the late Mr Murray, bookseller in Fleet-street, relate as a proof of his fimplicity. The peculiarity of his appearance, as he moved along (a short square figure, with an air of dignity, in a black fuit, which heightened the scarlet of his cheeks and nose) fixed the attention of some gentlemen in the street. They addressed him in the dialect of his country. His heart, heavy as it must have been, from the precariousness of his fituation, and distance from his accustomed haunts, expanded at these agreeable sounds. A conversation ensued; and the parties, by common confent, adjourned to a tavern. Here the stranger was kindly welcomed to town; and, after the glass had circulated for a time, something was proposed by way of sober amusement-a game at cards, or whatever the Doctor might prefer. The Doctor had been too civilly treated to demur; but his purse was scantily furnished, and it was necessary to quit his new friends in fearch of a fupply. Mr Murray was the person to whom he had recourse: the reader will not wonder that his interference should have spoiled the adventure.

A London sharper, of another denomination, afterwards tried to make advantage by the Doctor. This was an ingenious speculator in public medicines. He thought a composition of the most powerful stimulants might have a run, under the title of Dr Brown's exciting pill; and, for the privilege of his name, offered him a fum in hand by no means contemptible, as well as a share of the contingent profits. Poor Brown,

needy as he was, fourned at the propofal.

After this period, his life affords little variety of incident. Like Avicenna, his time feems to have been fpent between his literary pursuits and his pleasures. A fplendid manner of living, without an income to support it, had become habitual to him: The confequence was, that, from inability to discharge certain debts he had contracted, he was thrown into the king's bench prison; from which, however, he was, not long afterwards, released by the exertions of a few firm friends, particularly Mr Maddison of Charing-cross, a gentleman univerfally respected for his well-known benevolence. As a proof of the activity he was still capable of exerting, it will be fufficient to mention, that he accomplished the translation of his Elementa, with the addition of the supplementary notes, within 23 days, having been informed that a translation of the same was about to be published by another person.

Shortly before his death, the ambaffador of the in just measure. king of Prussia, in the name of his master. made Dr Brown an offer of a fettlement in the court of Berlin;

As the terms on which he lived with his brethren cut off by an apoplexy early in the morning of the 7th Brown. of October 1788, the day fucceeding that on which he had delivered to a company of thirteen gentlemen the greater part of the introductory lecture to his fecond courfe. At his death, he was between 52 and 53 years of age. His remains were interred in the church yard of St James's, Picadilly; and the only monument left behind him to transmit his name to posterity is his own works; which, when perfonal prejudice no longer shall prevail against their ingenious author, cannot fail to procure him all that deserved celebrity which they have already, in part, obtained in the different countries of Europe.

> In 1787, he published his "Observations," without his name, which he afterwards, however, refers to in the Elements as his own. The "Enquiry," faid to be written by Dr Jones, and which was composed in as short a time as the generality of men would transcribe a work of its extent, we can affirm, from undoubted

authority, to be his production.

This sketch of the life of the unfortunate Dr Brown would be of very little value, if not followed by a view of his system; but to give a complete view of that systtem would far exceed the limits within which, in a work like this, fuch articles must be confined. We trust, therefore, that our readers will be satisfied with an abstract; and as we are neither the partisans nor opponents of the Doctor, and not very partial to any medical fystem whatever, we shall content ourselves with inferting, in this place, the view which Dr Beddoes has given of Dr Brown's fundamental propositions in the valuable observations which he has prefixed to his edition of the Elements of Medicine.

" The varied structure of organized beings (fays Dr Beddoes), it is the business of anatomy to explain. Consciousness, assisted by common observation, will distinguish animated from inanimate bodies with precision more than fufficient for all the ends of medicine. The cause of gravitation has been left unexplored by all prudent philosophers; and Brown, avoiding all useless disquisition concerning the cause of vitality, confines himfelf to the phenomena which this great moving principle in nature may be observed to produce. His most general propositions are easy of comprehension.

" 1. To every animated being is allotted a certain portion only of the quality or principle on which the phenomena of life depend. This principle is denomi-

nated excitability.

" 2. The excitability varies in different animals, and in the fame animal at different times. As it is more intense, the animal is more vivacious or more susceptible of the action of exciting powers.

" 3. Exciting powers may be referred to two classes. 1. External; as heat, food, wine, poilons, contagions, the blood, fecreted fluids, and air. 2. Internal; as the functions of the body itself, muscular exertion, thinking, emotion, and paffion.

"4. Life is a forced state; if the exciting powers are withdrawn, death enfues as certainly as when the excitability is gone.

"5 The excitement may be too great, too finall, or

" 6. By too great excitement, weakness is induced, because the excitability become defective; this is indiduring the negociation of which, he was unexpectedly rect debility: when the exciting powers or stimulants I we, are withheld, weakness is induced; and this is direct debility. Here the excitability is in excess.

"7. Every power that acts on the living frame is Aimulant, or produces excitement by expending excitability. Thus, although a person, accustomed to animal food, may grow weak if he lives upon vegetables, still the vegetable diet can only be considered as producing an effect, the fame in kind with animals, though inferior in degree. Whatever powers, therefore, we imagine, and however they vary from fuch as are habitually applied to produce due excitement, they can only weaken the fystern by urging it into too much motion, or suffering it to fink into languor.

" 8. Excitability is feated in the medullary portion of the nerves, and in the muscles. As soon as it is anywhere affected, it is immediately affected everywhere; nor is the excitement ever increased in a part, while it is generally diminished in the system; in other words, different parts can never be in opposite states of excitement.

"I have already spoken of an illustration, drawn up by Mr Christie from a familiar operation, to facilitate the conception of Brown's fundamental positions. I introduce it here as more likely to answer its purpose than if separately placed at the end of my preliminary observations. 'Suppose a fire to be made in a grate, filled with a kind of fuel not very combustible, and which could only be kept burning by means of a machine containing feveral tubes, placed before it, and confiantly pouring streams of air into it. Suppose also a pipe to be fixed in the back of the chimney, through which a constant supply of fresh fuel was gradually let down into the grate, to repair the waste occasioned by the flame, kept up by the air machine.

'The grate will represent the human frame; the fuel in it, the matter of life-the excitability of Dr Brown, and the fenforial power of Dr Darwin; the tube behind, supplying fresh fuel, will denote the power of all living fystems, constantly to regenerate or reproduce excitability; while the air machine, of feveral tubes, denotes the various stimuli applied to the excitability of the body; and the flame drawn forth in contequence of that application represents life, the product of the

exciting powers acting upon the excitability.

'As De Brown has defined life to be a forced state, it is fitly represented by a flame forcibly drawn forth from fuel little disposed to combustion, by the constant application of streams of air poured into it from the different tubes of a machine. If some of these tubes are supposed to convey pure or dephlogisticated air, they will denote the highest class of exciting powers, opium, musk, camphor, spirits, wine, tobacco, &c. the diffusible stimuli of Dr Brown, which bring forth for a time a greater quantity of life than usual, as the blowing in of pure air into a fire will temporarily draw forth an uncommon quantity of flame. If others of the tubes be supposed to convey common or atmospheric air, they will represent the ordinary exciting powers, or stimuli, applied to the human frame, fuch as heat, light, air, food, drink, &c. while fuch as convey impure and inflammable air may be used to denote what have formerly been termed fedative powers, fuch as poisons, contagious miasmata, foul air, &c.

The reader will now probably be at no loss to understand the seeming paradox of the Brunonian system;

SUPPL. VOL. I. Part I.

dy, though they support life, yet consume it; for he Brown. will fee, that the application of these powers, though it brings forth life, yet at the same time it wastes the excitability or matter of life, just as the air blown into the fire brings forth more flame, but wastes the fuel or matter of fire. This is conformable to the common faying, "the more a spark is blown, the brighter it burns, and the sooner it is spent." A Roman poet has given us, without intending it, an excellent illustration of the Brunonian system, when he says,

" Balnea, vina, Venus, consumunt corpora nostra;

" Sed vitam faciunt balnea, vina, Venus.

"Wine, warmth, and love, our vigour drain; "Yet wine, warmth, love, our life fustain."

Or to translate it more literally,

" Baths, women, wine, exhaust our frame;

" But life itself is drawn from them."

Equally easy will it be to illustrate the two kinds of debility, termed direct and indirect, which, according to Brown, are the cause of all diseases. If the quantity of stimulus, or exciting power, is proportioned to the quantity of excitability, that is, if no more excitement is drawn forth than is equal to the quantity of excitability produced, the human frame will be in a stare of health, just as the fire will be in a vigorous state when no more air is blown in than is sufficient to confume the fresh fupply of tuel constantly poured down by the tube behind. If a fufficient quantity of stimulus is not applied, or air not blown in, the excitability in the man, and the fuel in the fire, will accumulate, producing direct debility; for the man will become weak, and the fire low. Carried to a certain degree, they will occasion death to the first, and extinction to the last. If, again, an over proportion of stimulus be applied, or too much air blown in, the excitability will foon be wasted, and the matter of fuel almost spent. Hence will arise indirect debility, producing the same weakness in the man, and lowness in the fire, as before, and equally terminating, when carried to a certain degree, in death and extinction.

' As all the diseases of the body, according to Dr Brown, are occasioned by direct or indirect debility, in confequence of too much or too little stimuli, so all the defects of the fire must arise from direct or indirect lownels, in consequence of too much or too little air blown into it. As Brown taught that one debility was never to be cured by another, but both by the more judicious application of stimuli, so will be found the case in treating the defects of the fire. If the fire has become low, or the man weak, by the want of the needful quantity of stimulus, more must be applied, but very gently at first, and increased by degrees, lest a strong stimulus applied to the accumulated excitability should produce death; as in the case of a limb benumbed with cold (that is, weakened by the accumulation of its excitability in consequence of the abstraction of the usual stimulus of heat), and fuddenly held to the fire, which we know from experience is in danger of mortification, or as in the case of the fire becoming very low by the accumulation of the matter of fuel, when the feeble flame, affailed by a fudden and ftrong blaft of air, would be overpowered and put out, instead of being nourished that food, drink, and all the powers applied to the bo- and increased. Again, if the man or the fire have been

much stimulus, we are not suddenly to withdraw the whole, or even a great quantity of the exciting powers much upon the dependence of life on external causes, or air, for then the weakened life and diminished flame might fink entirely; but we are by little and little to diminish the overplus of stimulus, so as to enable the excitability, or matter of fuel, gradually to recover its proper proportion. Thus a man who has injured his constitution by the abuse of spirituous liquors is not fuddenly to be reduced to water alone, as is the practice of some physicians, but he is to be treated as the judicious Dr Pitcairn of Edinburgh is said to have treated a Highland chieftain, who applied to him for advice in this fituation. The Doctor gave him no medicines, and only exacted a promife of him, that he would every day put in as much wax into the wooden queich, out of which he drank his whisky, as would receive the impression of his arms. The wax thus gradually accumulating, diminished daily the quantity of the whisky, till the whole queich was filled with wax; and the chieftain was thus gradually, and without injury to his constitution, cured of the habit of drinking spirits.

'These analogies might be pursued farther; but my object is folely to furnish some general ideas, to prepare the reader for entering more easily into the Brunonian theory, which I think he will be enabled to do after perufing what I have faid. The great excellence of that theory, as applied, not only to the practice of physic, but to the general conduct of the health, is, that it impresses on the mind a sense of the impropriety and danger of going from one extreme to another. The human frame is capable of enduring great varieties, if time be given it, to accommodate itself to different flates. All the mischief is done in the transition from one state to another. In a flate of low excitement we are not rashly to induce a state of high excitement, nor when elevated to the latter, are we fuddenly to descend to the former, but step by step, and as one who from the top of a high tower descends to the ground. From hasty and violent changes, the human frame always fuffers; its particles are torn afunder, its organs injured, the vital principle impaired, and difease, often death, is the

inevitable consequence.

I have only to add, that though in this illustration of the Brunonian fystem (written several years ago), I have spoken of a tube constantly pouring in fresh fuel, because I could not otherwise convey to the reader a familiar idea of the power possessed by all living systems, to renew their excitability when exhausted; yet it may be proper to inform the student, that Dr Brown supposed every living system to have received at the beginning its determinate portion of excitability; and, therefore, although he spoke of the exhaustion, augmentation, and even renewal of excitability, I do not think it was his intention to induce his pupils to think of it as a kind of fluid substance existing in the animal, and fubject to the law by which fuch fubstances are governed. According to him, excitability was an unknown fomewhat, subject to peculiar laws of its own, and whose different states we were obliged to describe (though inaccurately) by terms borrowed from the qualities of material fubstances.'

"The Brunonian system has frequently been charged with promoting intemperance. The objection is

Brown: rendered indirectly weak, by the application of too ferious; but the view already given of its principles Brown, shews it to be groundless. No writer had infifted so or fo strongly stated the inevitable consequences of excess. And there are no means of promoting morality upon which we can rely, except the knowledge of the true relations between man and other beings or bodies. For by this knowledge we are directly led to shun what is hurtful, and purfue what is falutary: and in what else does moral conduct, as far it regards the individual, confist?, It may be faid that the author's life disproves the justness of this representation: his life, however, only shews the superior power of other causes, and of bad habits in particular; and I am ready to acknowledge the little efficacy of instruction when bad habits are formed. Its great use consists in preventing their formation; for which reason popular intruction in medicine would contribute more to the happiness of the human species, than the complete knowledge of every thing which is attempted to be taught in education, as it is conducted at present. But though the principles of the system in question did not correct the propensities of its inventor, it does not follow that they tend to produce the same propensities in others."

BRUCE (James, Efq; F. R. S.), the celebrated Abyssinian traveller, was born, 1730, at Kinnaird house, in the parish of Larbert and county of Stirling. His descent by both parents was ancient and honourable; and of that descent he was, perhaps, too proud. His grandfather was --- Hay Efq; of Woodcockdale, in the county of Linlithgow, who, marrying Miss Bruce, the heiress of Kinnaird, gave the name of Bruce to all

his descendants.

Perhaps this change of name may have taken place in obedience to the deed by which the estate of Kinnaird was settled on Mrs Hay's children; but it is a change which, in a country like Scotland, where antiquity of defcent is highly valued, any man would voluntarily have adopted, who had married the heiress of fuch a family. The Bruces of Kinnaird had been in possession of that estate for three centuries: they were descended from a younger son of Robert de Bruce, the competitor with Baliol for the crown of Scotland. It would readily occur, that the knowledge of fuch a defcent would be best preserved by continuing the name of their great ancestor; and we have reason to believe, that the subject of this memoir was not much delighted when put in mind, as he frequently was, that, though the heir of the line, he was not the male heir of that branch of the illustrious family.

As he was allied to royalty by his father and grandmother, through his mother he was related to some of the most respectable families in the kingdom. She was the daughter of James Graham, Esq; of Airth, dean of the faculty of advocates, and judge of the high court of admiralty in Scotland, by Marion daughter of James Hamilton, Esq; of Pencaitland; and to a man of our traveller's turn of mind, there can be no doubt but that it must have afforded much satisfaction to think, that no family ranks higher in Scotland than those of Bruce, Graham, and Hamilton. In him, however, it was weakness to be proud, if indeed he was proud, of family; for the talents bestowed upon him by nature, or, to speak more properly, by nature's God, would have made him great though he had been born on a dunghill. He would indeed have been, in all probability, much greater than he was, had he not been in possession of the phantom of birth to gratify much of his ambition; for the facility with which he mastered every study in which he engaged, would have carried him quickly to the top

of the most honourable profession.

Mr Bruce was instructed in grammatical learning at the school of Harrow on the Hill, in the county of Middlefex, where he gave the most unequivocal proofs of genius, and acquired a very confiderable knowledge of the Greek and Latin languages. It was customary with him to perform, not only his own exercises, but also the exercises of such of his companions as were not equal to the task themselves. Among these was his maternal uncle, who was frequently indebted to his affiltance, and, on one occasion, produced a copy of verses of his composition, which excited, not only the applause, but the admiration of their mafter. Mr Graham, who was but a few months older than Mr Bruce, had, for some transgression (we know not what), been punished, as boys in the great schools in England arc often punished, by having a task fet him, which he foon found bimself unable to perform. His nephew desired him to be under no uneafinefs, promifing to furnish him with the verses before the time at which they were to be given in. He was as good as his word; but the master of the school soon discovering that they were not the performance of Mr Graham, exclaimed, that the author of these verses, whoever he was, might apply to himself the words of Horace,

- Sublimi feriam sidera vertice.

While Mr Bruce was at Harrow, and for a year or two after he had left it, he was of a very delicate frame, and appeared to his friends to be threatened with a confumption. The truth is, that he was uncommonly tall for his age, and felt all the feebleness of joints and other bodily weaknesses to which overgrown boys are generally subject. His father intended him for the protession of the law; and, upon his return from Harrow, he was entered into the university of Edinburgh, where he went through a regular course of fludy to fit him for being inrolled in the body of advocates; but for fome reason, which we do not perfectly know, he relinquished the study of law for the pursuits of trade; and, going to London, entered into partnership with a wine-merchant of the name of Allen, whose daughter he married.

That lady falling into a bad state of health, Mr Bruce took her abroad, in hopes that travelling would be attended with beneficial effects; but in these he was disappointed, as she died within a year after her marriage. He was induced, in order to dispel his grief, to continue his travels; during which his father dying (at Edinburgh, 4th May 1758), the inheritance of his ancestors devolved upon him, and he returned to Britain. Some of his subsequent transactions shall now be

related in his own words.

" Every one will remember that period, fo glorious to Britain, the latter end of the ministry of the late earl of Chatham. I was then returned from a tour thro' the greatest part of Europe, particularly through the whole of Spain and Portugal, between whom there was then the appearance of an approaching war.

"I was about to retire to a small patrimony I had

received from my ancestors, in order to embrace a life Bruce. of fludy and reflection, nothing more active appearing within my power, when chance threw me unexpectedly into a very short and very defultory conversation with Lord Chatham.

" It was a few days after this, that Mr Wood, then under fecretary of state, my zealous and sincere friend, informed me that Lord Chatham intended to employ me upon a particular fervice; that, however, I might go down for a few weeks to my own country to fettle my affairs, but, by all means, to be ready upon a call. Nothing could be more flattering to me than fuch an offer, when fo young; to be thought worthy by Lord Chatham of any employment, was doubly a preference. No time was lost on my side; but just after receiving orders to return to London, his lordship had gone to Bath, and refigned his office.

"This disappointment, which was the more sensible to me that it was the first I had met with in public life, was promifed to be made up to me by Lord Egremont and Mr George Grenville. The former had been long my friend; but unhappily he was then far gone in a lethargic indisposition, which threatened, and did very foon put a period to his existence. With Lord Egremont's death my expectations vanished. Further particulars are unnecessary; but I hope that, at least in part, they remain in that breast where they naturally ought to be, and where I shall ever think, not to be

long forgotten, is to be rewarded.

"Seven or eight months were passed in an expensive and fruitless attendance in London, when Lord Halifax was pleafed, not only to propofe, but to plan for me a journey of confiderable importance, and which was to take up feveral years. His lordship said, that nothing could be more ignoble than, at fuch a time of life, at the height of my reading, health, and activity, I should, as it were, turn peafant, and voluntarily bury mysels in obscurity and idleness; that though war was now drawing fast to an end, full as honourable a competition remained among men of spirit, which should acquit themfelves best in the dangerous line of useful adventure and discovery.

" He observed, that the coast of Barbary, which might be faid to be just at our door, was yet but partially explored by Dr Shaw, who had only illustrated (very judiciously indeed) the geographical labours of Sanson; that neither Dr Shaw nor Sanson had been, or pretended to be, capable of giving the public any detail of the large and magnificent remains of ruined architecture, which they both vouch to have feen in great quantities, and of exquifite elegance and perfection, all over the country. Such had not been their fludy, yet such was really the taste that was required in the present times. He wished, therefore, that I should be the first, in the reign just now beginning, to fet an example of making large additions to the royal collection; and he pledged himself to be my support and patron, and to make good to me, upon this additional merit, the promites which had been held forth to me by former ministers for other services.

"The discovery of the source of the Nile was also a fubject of their conversations, but it was always mentioned to me with a kind of diffidence, as if to be expected from a more experienced traveller. Whetlier this was but another way of exciting me to the atdid me justice to suggest, that this too was either to be atchieved by me, or to remain as it had done for these last 2000 years, a defiance to all travellers, and an opprobrium to geography.

" Fortune seemed to enter into this scheme. At the very instant, Mr Aspinwall, very cruelly and ignominiously treated by the dey of Algiers, had resigned his confulship, and Mr Ford a merchant, formerly the dey's acquaintance, was named in his place. Mr Ford was appointed, and, dying a few days after, the confulship became vacant. Lord Halifax pressed me to accept of this as containing all forts of conveniences for making

the proposed expedition.

"This favourable event finally determined me. I had all my life applied unweariedly, perhaps with more love than talent, to drawing, the practice of mathematics, and especially that part necessary to astronomy. The transit of Venus was at hand. It was certainly known that it would be visible once at Algiers, and there was great reason to expect it might be twice. had furnished myself with a large apparatus of instruments, the completest of their kind, for the observation. In the choice of these, I had been affished by my friend Admiral Campbell, and Mr Ruffel, secretary to the Turkey Company: every other necessary had been provided in proportion. It was a pleafure now to know that it was not from a rock or a wood, but from my own house at Algiers, I could deliberately take measures to place myself in the list of men of science of all nations, who were then preparing for the fame scientific purpose.

"Thus prepared, I fet out for Italy, through France; and though it was in time of war, and some strong objections had been made to particular passports, solicited by our government from the French secretary of state, Monsieur de Choiseul most obligingly waved all such exceptions with regard to me, and most politely affured me, in a letter accompanying my paffport, that those difficulties did not in any shape regard me, but that I was perfectly at liberty to pais through, or remain in, France with those that accompanied me, without limiting their number, as short or as long a

time as should be agreeable to me.

"On my arrival at Rome, I received orders to proceed to Naples, there to await his majefty's further commands. Sir Charles Saunders, then with a fleet before Cadiz, had orders to visit Malta before he returned to England. It was faid that the grand master of that order had behaved so improperly to Mr Harvey (afterwards Lord Bristol) in the beginning of the war, and so partially and unjustly between the two nations in the course of it, that an explanation on our part was become necessary. The grand master no sooner heard of my arrival at Naples, than, guesfing the errand, he fent off Chevalier Mazzini to London, where he at once made his peace and his compliments to his majesty upon his accession to the throne.

" Nothing remained now but to take possession of my confulship. I returned, without loss of time, to Rome, and from thence to Leghorn, where having embarked on board the Montreal man of war, I proceeded

"While at Naples, I received from flaves, redeemed

Bruce. tempt I shall not say; but my heart, in that instant, from the province of Constantine, accounts of magnis. Bruce. cent ruins they had feen while traverfing that country with their master the Bey. I saw the absolute necessity there was for affiftance, without which it was impossible for any one man, however diligent and qualified, to do any thing but bewilder himself. All my endeavours, however, had hitherto been unfuccessful to persuade any Italian to put himself wilfully into the hands of a people constantly looked upon by them in no better light than pirates. At last Mr Lumisden, by accident, heard of a young man who was then fludying architecture at Rome, a native of Bologna, whose name was Luigi Balugani. I can appeal to Mr Lumisden as to the extent of this person's practice and knowledge, and that he knew very little when first fent to me. In the twenty months which he staid with me at Algiers, by affiduous application to proper subjects under my instruction, he became a very confiderable help to me, and was the only one that ever I made use of, or that attended me for a moment, or ever touched one reprefentation of architecture in any part of my journey."

> Our traveller, when in Spain, had endeavoured to find access to that immense collection of Arabic manufcripts which were perishing in the dust of the escurial: but in vain. "All my fuccefs (fays he) in Europe terminated in the acquisition of those few printed Arabic books that I had found in Holland; and these were rather biographers than general historians, and contained little in point of general information. The fludy of thele, however, and of Maracci's Koran, had made me a very tolerable Arab; a great field was opening before me in Africa to complete a collection of manuscripts,

an opportunity which I did not neglect.

" After a year spent at Algiers, constant conversation with the natives while abroad, and with my manufcripts within doors, had qualified me to appear in any part of the continent without the help of an interpreter. Ludolf had affured his readers, that the knowledge of any oriental language would foon enable them to acquire the Ethiopic; and I needed only the same number of books to have made my knowledge of that language go hand in hand with my attainments in the Arabic. My immediate prospect of setting out on my journey to the inland parts of Africa, had made me double my diligence; night and day there was no relaxation from these studies, although the acquiring any fingle language had never been with me either an object of time or difficulty."

At Algiers Mr Bruce was detained longer than he expected, in contequence of a dispute with the Dey concerning Mediterranean paffes. This being adjusted, he proceeded to Mahon, and from Mahon to Carthage. He next vifited Tunis and Tripoli, and travelled over the interior parts of thele states. At Bengazi, a small town on the Mediterranean, he fuffered shipwreck, and with extreme difficulty faved his life, though with the lois of all his baggage. He afterwards failed to the isles of Rhodes and Cyprus, and proceeding to Afia Minor, travelled through a confiderable part of Syria and Palestine, visiting Hassia, Latikea, Aleppo, and Tripoli; near which last city he was again in imminent danger of perishing in a river. The ruins of Palmyra and Baalbec were next carefully furveyed and sketched by him; and his drawings of these places are deposited by a subject to his fovereign."

It is much to be regretted that Mr Bruce published no particular account of these various journeys; from the nature of the places visited, and the abilities of the man, much curious and ufeful information might have been expected. Some manuscript accounts of different parts of them are faid to have been left by him, but whether in tuch a state as to be fit for publication, we have not learned.

In these various travels some years were passed; and Mr Bruce now prepared for the grand expedition, the accomplishment of which had ever been nearest his heart, the discovery of the sources of the Nile. In the profecution of that dangerous object, he left Sidon on the 15th of June 1768, and arrived at Alexandria on the 20th of that month. He proceeded from thence to Cairo, where he continued to the 12th of December following, when he embarked on the Nile; and in a very extraordinary boat, called a canja, of which he fays the main-fail yard was about 200 feet in length, he failed up that river as far as Syene, visiting in the course of his voyage the ruins of Thebes, and the place where Memphis once flood, now known by the name of Metrahenny. Leaving Kenne on the Nile, 16th February 1760, he croffed the defert of the Thebaid to Coffeir on the Red Sea, and arrived at Jidda on the 3d of May. In Arabia Felix he remained, not without making feveral excursions, till the 3d of September, when he sailed from Loheia, and arrived on the 19th at Masuah, where he was detained near two months by the treachery and avarice of the Naybe of that place. It was not till the 15th of November that he was allowed to quit Arkeeko, near Matua; and he arrived on the 15th of February 1770 at Gondar, the capital of Abysfinia, where he ingratiated himfelt with the most considerable persons. of both fexes belonging to the court. This he accomplished by being a physician in the city, a soldier in the field, a courtier everywhere, demeaning himfelf as conscious that he was not unworthy of being a companion to the first of their nobility, and the king's guest, which is there a character, as it was with eastern nations of old, to which a certain fort of consideration is due. "To this I may add (fays he), that, being in the prime

of life, of no ungracious figure, having an accidental Bruce. knack, which is not a trifle, of putting on the drefs, and speaking the language easily and gracefully, I cultivated, with the utmost assiduity, the friendship of the fair fex, by the most modest and respectful distant attendance and obsequiousness in public, abating just as much of that in private as fuited their humours and inclination;" and jealoufy being a passion unknown in Abyffinia, he thus acquired from the ladies great support at court.

Several months were employed in attendance on the king, and in an unsuccessful expedition round the lake of Dambea. Towards the end of October Mr Bruce fet out for the fources of the Nile; at which long defired spot he arrived on the 14th of November; and his feelings on the accomplishment of his wishes cannot bet-

ter be expressed than in his own words:

" It is easier to guess than to describe the situation of my mind at that moment; standing in that spot which had baffled the genius, industry, and inquiry, of ancients and moderns for the course of near 3000 years. Kings had attempted this discovery at the head of armies, and each expedition was distinguished from the last only by the difference of the numbers which had perished, and agreed alone in the disappointment which had uniformly, and without exception, followed them all. Fame, riches, and honour, had been held out for a feries of ages to every individual of those myriads those princes commanded, without having produced one man capable of gratifying the curiofity of his fovereign, or wiping off this stain upon the enterprise and abilities of mankind, or adding this defideratum for the encouragement of geography. Though a mere private Briton, I triumphed here in my own mind over kings and their armies; and every comparison was leading nearer and nearer to the prefumption, when the place itself where I flood, the object of my vain glory, fuggefted what depressed my short-lived triumphs."

If these triumphs were short lived, they were equally ill founded; for if the fource of the Nile was feen by Mr Bruce, there can be no doubt of its having been likewise seen by the Portuguese jesuits. Or this we have elsewhere brought forward sufficient proof; and the candid reader, who shall take the trouble to compare the extract printed at the bottom of this page (A),

with

(A) " In the eastern part of this kingdom, on the declivity of a mountain, whose descent is so easy that it feems a beautiful plain, is that fource of the Nile which has been fought after at fo much expence of labour, and about which such variety of conjectures hath been formed without success. This spring, or rather these two springs, are two holes, each about two feet diameter, a stone's cast distant from each other. The one is about five feet and an half in depth, at least we could not get our plummet farther, perhaps because it was stopped by roots, for the whole place is full of trees: of the other, which is somewhat less, with a line of ten feet we could find no bottom, and were affured by the inhabitants that none ever had been found. It is believed here that these springs are the vents of a great subterraneous lake; and they have this circumstance to avour their opinion, that the ground is always moilt, and fo foft that the water boils up under foot as one walks upon it. Such is the ground sound about these fountains. At a little distance to the south is a village named Guix (the Geest of Mr Bruce), through which the way lies to the top of the mountain, whence the traveller discovers a vast extent of land, which appears like a deep valley, though the mountain rifes fo imperceptibly, that those who go up or down it are scarce sensible of any declivity." - Johnson's Translation of Father Lobo's Voyage to Abyssinia, Chap. X.

The only difference between Lobo's and Bruce's account of these fountains worthy of notice is, that the former found but two, while the latter found three holes; but Bruce fays expressly, that the holes are partly artificial; and Lobo's description of them indicates the same thing. It is therefore not improbable that there may

now be four or five holes.

Beuce. with our traveller's account of these coy fountains, as it stands in his own book or in our article NILE (Encycl.), will be convinced that it was ridiculous in Mr Bruce, and is equally ridiculous in his friends, to pretend that he discovered what had bassled the genius of inquiry for

BRU

the course of near 3000 years.

It was not, however, the consciousness of having been anticipated by the jefuits (for these he without ceremony calls a fet of liars), but the prospect of danger to be encountered on his return to Europe, that cast fuch a damp on his present enjoyment. "I was but a few minutes (fays he) arrived at the fource of the Nile, through numberless dangers and sufferings, the least of which would have overwhelmed me, but for the continual goodness and protection of Providence; I was, however, but then half through my journey, and all those dangers which I had already passed awaited me again on my return. I found a despondency gaining ground fast upon me, which blasted the crown of laurels I had too rashly woven for myself."

When he returned to rest the night of that discovery, repose was fought for in vain. "Melancholy reflections upon my present state, the doubtfulness of my return in fafety, were I permitted to make the attempt, and the fears that even this would be refused, according to the rule observed in Abyssinia with all travellers who have once entered the kingdom; the consciousness of the pain that I was then occasioning to many worthy individuals, expecting daily that information concerning my fituation which it was not in my power to give them; some other thoughts perhaps, still nearer the heart than those, crowded upon my mind, and forbade all approach

of fleep.

" I was, at that very moment, in possession of what had for many years been the principal object of my ambition and wishes; indifference which, from the usual infirmity of human nature, follows, at least for a time, complete enjoyment, had taken place of it. The marsh, and the fountains, upon comparison with the rife of many of our rivers, became now a trifling object in my fight. I remembered that magnificent scene in my own native country, where the Tweed, Clyde, and Annan, rife in one hill; three rivers I now thought not inferior to the Nile in beauty, preferable to it in the cultivation of those countries through which they flow; superior, vastly superior to it in the virtues and qualities of the inhabitants, and in the beauty of its flocks, crowding its pastures in peace, without fear of violence from man or beaft. I had seen the rise of the Rhine and Rhone, and the more magnificent fources of the Soane; I began, in my forrow, to treat the inquiry about the source of the Nile as a violent effort of a diftempered fancy, What's Hecuba to him, or he to Hecuba,

'That he should weep for her?'

sleep, I started from my bed in the utmost agony; I

promote or to interrupt my flumbers, but the coolness Bruce, and ferenity of the night braced my nerves, and chafed away those phantoms that while in bed had oppreffed and tormented me.

"It was true that numerous dangers, haidships, and forrows, had befet me through this half of my excurfion; but it was Itill as true, that another Guide, more powerful than my own courage, health, or understanding, if any of them can be called man's own, had uniformly protected me in all that tedious half. I found my confidence not abated, that fill the fame Guide was able to conduct me to my wished for home. I immediately refumed my former fortitude, confidered the Nile as indeed no more than rifing from iprings as all other rivers do, but widely differing in this, that it was the palm for 3000 years held out to all the nations of the world as a detur dignissimo, which in my cool hours I had thought was worth the attempting at the risk of my life, which I had long either resolved to lose, or lay this discovery a trophy in which I could have no competitor, for the honour of my country, at the feet of

my fovereign, whose fervant I was."

How unworthy is this ranting reflection of the greatness of mind which Mr Bruce on other occasions unquestionably displayed! Had he indeed been the first European who discovered those pitiful holes from which the Nile is faid to flow, his merit would not have confisted in travelling from Gondar to the village Geesh, and viewing the fountains which are at that village the objects of idolatrous adoration, but in the address with which he contrived to make himfelf the favourite of all the factions which agitated a barbarous and almost inhuman nation. In managing those factions, he was indeed great; but he scems to have valued himself more upon looking at three tprings, of which it is far from being certain that they are the fources of the Nile (see NILE, Encycl.), and of which two had certainly been examined more than a century before he was born, by different missionaries from the kingdom of Portugal! This, however, he calls the object of his wifhes; and having now accomplished it, he bent his thoughts on his return to his native country.

He arrived at Gondar on the 19th November 1770; but found, after repeated solicitations, that it was by no means an easy task to obtain permission to quit Abysfinia. A civil war in the mean time breaking out (no uncommon occurrence in that barbarous country), feveral engagements took place between the king's forces and the troops of the rebels, particularly three actions at a place called Serbraxos on the 19th, 20th, and 23d of May 1771. In each of them Mr Bruce acted a confiderable part, and for his valiant conduct in the fecond received, as a reward from the king, a chain of gold, of 184 links, each link weighing 3 to dwts. or somewhat more than 21 lbs. troy in all. At Gondar, after these Grief and despondency now rolling upon me like a tor- , enagements, he again preferred the most earnest entrearent, relaxed, not refreshed, by unquiet and impersect ties to be allowed to return home, intreaties which were long refisted; but his health at last giving way, from went to the door of my tent, every thing was still; the the anxiety of his mind, the king confented to his de-Nile, at whose head I stood, was not capable either to parture, on condition of his engaging by oath (B) to

return

⁽B) With regard to this oath, Mr Bruce fays, that he hopes the difficulty of performing it extinguished the he of breaking it; and that, at any rate, it being merely perional, his engagement to return ceased with the death of the king, of which he received intelligence during his stay at Sennaar.

return to him in the event of his recovery, with as ma- lic and private difpatches. Such was the worthy conny of his kindred as he could engage to accompany

After a residence of nearly two years in that wretched country, Mr Bruce left Gondar on the 16th of December 1771, taking the dangerous way of the defart of Nubia, in place of the more easy road of Masuah, by which he entered Abyssinia. He was induced to take this route from his knowledge and former experience of the cruel and favage temper of the Naybe of Masuah. Arriving at Teawa the 21st March 1772, he had the misfortune to find the Shekh Fidele of Atbara, the counterpart of the Naybe of Masuah, in every bad quality; by his intrepidity and prudence, however, and by making good use of his foreknowledge of an eclipse of the moon, which happened on the 17th of April, he was permitted to depart next day, and he arrived at

Sennaar on the 29th of the same month. Mr Bruce was detained upwards of four months at that miserable and inhospitable place; the inhabitants of which he describes in these expressive words: "War and treason seem to be the only employment of these horrid people, whom heaven has separated by almost impassable deserts from the rest of mankind, confining them to an accurfed fpot, feemingly to give them an earnest in time of the only other worse which he has referved to them for an eternal hereafter." This delay was occasioned by the villany of those who had undertaken to supply him with money; but at last, by dispoling of 178 links of his gold chain, the well-earned

trophy of Serbraxos, he was enabled to make preparation for his dangerous journey through the deferts of

He left Sennaar on the 5th of September, and arrived on the 3d of October at Chendi, which he quitted on the 20th, and travelled through the defert of Gooz, to which village he came on the 26th of October. On the 9th of November he left Gooz, and entered upon the most dreadful and dangerous part of his journey; the perils attending which he has related with a power of pencil not unworthy of the greatest masters. All his camels having perished, Mr Bruce was under the necessity of abandoning his baggage in the defert, and with the greatest difficulty reached Assouan upon the Nile on the 29th of November.

After some days rest, having procured fresh camels, he returned into the defert, and recovered his baggage, among which is particularly to be remarked a quadrant (of three feet radius) supplied by Louis XV. from the Military Academy at Marfeilles; by means of which noble instrument, now deposited in the museum at Kinnaird, Mr Bruce was enabled with precision and accuracy to fix the relative fituations of the feveral remote

places he visited.

On the 1cth of January 1773, after more than four years absence, he arrived at Cairo, where, by his manly and generous behaviour, he fo won the heart of Maho. met Bey, that he obtained a firman, permitting the commanders of English vessels belonging to Bombay and Bengal to bring their ships and merchandise to Suez, a place far preserable in all respects to Jidda, to which they were formerly confined. Of this permiffion, which no European nation could ever before acquire, many English veffels have fince availed themfelves; and it has proved peculiarly useful both in pub-

clusion of his memorable journey through the defeit; a journey which, after many hardships and dangers, terminated in obtaining this great national benefit.

At Cairo Mr Bruce's earthly career had nearly been concluded by a diforder in his leg, occasioned by a worm in the flesh This accident kept him five weeks in extreme agony, and his health was not re-established till a twelvemonth afterwards, at the baths of Poiretta in Italy. On his return to Europe, Mr Bruce was received with all the admiration due to fo exalted a character. After passing some considerable time in France, particularly at Montbard, with his friend the Comte de Buffon, by whom he was received with much hospitality, and is mentioned with great applause, he at last revisited his native country, from which he had been upwards of twelve years absent.

It was now expected that he would take the earliest opportunity of giving to the world a narrative of his travels, in which the public curiofity could not but be deeply interested. But several circumstances contributed to delay the publication; and what these were will

be best related in his own words:

" My friends at home gave me up for dead; and as my death must have happened in circumstances difficult to have been proved, my property became as it were a hareditas jacens, without an owner, abandoned in common to those whose original title extended no further

than temporary possession.

" A number of law-fuits were the inevitable confequences of this upon my return. To these disagreeable avocations, which took up much time, were added others still more unfortunate. The relentless ague, caught at Bengazi, maintained its ground, at times, for a space of more than 16 years, though every remedy had been used, but in vain; and what was worst of all, a lingering diftemper had feriously threatened the life of a most near relation (his fecond wife), which, after nine years constant alarm, where every duty bound me to attention and attendance, conducted her at last, in very early life, to her grave."

Amidst the anxiety and the distress thus occasioned Mr Bruce was by no means neglectful of his private affairs. He confiderably improved his landed property. inclosing and cultivating the waste grounds, and he highly embellished his paternal seat, making many additions to the house, one in particular of a noble museum, filled with the most precious stores of oriental literature, large collections of drawings made, and curious articles obtained, during his far extended peregrinations. An excellent stratum of coal at Kinnaird drew much of his attention; he erected steam engines of the most approved construction, and placed his coalliery on such a sooting that, at the period of his decease, it produced about

2000l. a-year.

The termination of some law-fuits, and of other business, which had occupied much of his time, having at length afforded leifure to Mr Bruce to put his materials in order, his greatly defired and long expected work made its appearance in 17.90, in five large quartovolumes, embellished with plates and charts. It is unnecessary, and night be tedious, to enter at present into any critic or analysis of this celebrated work. It is univerfally allowed to be replete with much curious and useful information; and to abound in narratives which

Bruce. at once excite our admiration and interest our feelings. The very fingular and extraordinary picture which it gives of Abyffinian manners, startled the belief of some; but these manners, though strange in the fight of an European, are little more than might be expected in fuch a barbarous country; and had an enlightened philosopher visited Scotland in the times of our earliest monarchs, he might perhaps have witneffed and related fcenes, different indeed from what Mr Bruce faw in Abysfinia, but which to us would have seemed equally strange.

A more ferious objection to the truth of Mr Bruce's narrative was flarted by an anonymous, but able, cri-* Supposed tic*, in an Edinburgh newspaper, soon after the publication, from the account of two astronomical pheprofessor of nomena, which could not possibly have happened, as Mr natural phi- Bruce afferts. The first of these is the appearance losophy in of the new moon at Furshout, during Mr Bruce's the univer- flay in that place, which he mentions to have been Andrew's from 25th December 1768 to the 7th of January 1769; and on a particular day in that interval afferts. that the new moon was feen by a fakir, and was found by the ephemerides to be three days old; whereas it is certain that the moon change! on the 8th of January 1769. The other phenomenon appears equally impoffible. At Teawa Mr Bruce fays he terrified the Shekh by feretelling that an eclipse of the moon was to take place at four afternoon of the 17th of April 1772; that accordingly, foon after that hour, he faw the eclipfe was begun; and when the shadow was half over, told the Shekh that in a little time the moon would be totally darkened. Now, by calculation, it is certain, that at Teawa this eclipse must have begun at 36 minutes past four, and the moon have been totally covered at 33 minutes past five; while the sun set there a few minutes past fix, before which time the moon, then in opposition, could not have risen: fo that as the moon rose totally eclipsed, Mr Bruce could not see the shadow half over the disk, nor point it out to the Shekh To these objections, which appear unfurmountable, Mr Bruce made no reply, though in conversation he said he would do it in the second edition of his book.

These are mistakes which can hardly be accounted for by attributing them to the inaccuracy of his notes, or indeed to any cause which we are inclined to name; and perhaps he has fallen into a mistake of the same kind in his account of the enormous main-fail yard of the canja, in which he failed up the river Nile. To every man who has but dipped into the science of mechanics, it is known that a beam of wood 200 feet in length, must be of proportional thickness, or it would fall in pieces by its own weight. This thickness must be greatly increased, to enable it to bear the strain oceassoned by a prodigious fail filled with wind; and those only who have been at the Nile, and have feen the can jas, can fay, whether these vessels, or indeed any vesfels which can be employed on that river, would not be overfet by yards,

- To equal which, the tallest pine Hewn on Norwegian hills, to be the mast Of some great admiral, were but a wand.

The language of the work is in general harsh and unpolished, though sometimes animated. Too great a

parent facility with which the traveller gained the most Bruce. familiar access to the courts, and even to the harams of the fovereigns of the countries through which he passed, is apt to create in readers some doubts of the accuracy of the narration. Yet there appears upon the whole fuch an air of manly veracity, and circumstances are mentioned with a minuteness so unlike deceit, that these doubts are overcome by the general impression of truth, which the whole detail irrefiftibly fastens upon the mind. The character of Ras Michael has often struck us, as containing very strong internal evidence of its having been taken from nature; for it is such a character, at once extraordinary and confiftent, as neither Mr Bruce, nor perhaps any writer fince Shakespeare, had genius to feign.

The first impression of the book being almost disposed of, Mr Bruce had slipulated with an eminent bookfeller in London for a second edition to be published, we think in 8vo; and he was bufy in preparing that edition for the press when death removed him from this transitory stage. On the 26th of April 1794 he entertained some company at Kinnaird house with his usual hospitality and elegance. About eight o'clock in the evening, when his quests were ready to depart, he was handing one of the ladies down stairs, when, having reached the feventh or eighth step from the bottom, his foot slipped, and he fell down headlong. He was taken up speechless; his face, particularly the forehead and temples, being feverely cut and bruifed, and the bones of his hands broken. He continued in a state of apparent infensibility for eight or nine hours, and expired on Sunday the 27th, in the 64th year of his age.

Mr Bruce's second wife, whom he married on the 20th May 776, was Mary, eldest daughter of Thomas Dundas, Esq; of Carron-hall, by Lady Janet Maitland, daughter of Charles fixth Earl of Landerdale. By that lady, who, a'ter a fevere and lingering indisposition, died in 1784, he had three children, of whom one

fon and one daughter furvive him.

Mr Bruce's person was large, his height exceeding fix feet, his bulk being in proportion to his height; and at the period when he entered on his dangerous expedition, he was equally remarkable for strength and for agility. To those who never beheld him, the engraved medallion in the title pages of the first and third volumes of his Travels will convey fome idea of his features. He excelled in all manly accomplishments, being trained to exercise and fatigue of every kind. He was a hardy, practifed, and indefatigable swimmer; and his long residence among the Arabs had given him a more than ordinary facility in managing the horse. In the use of fire arms he was fo unerring, that in innumerable inftances he never failed to hit the mark; and his dexterity in handling the spear and lance on horseback was also uncommonly great. He was master of most languages; and was fo well skilled in oriental literature, that he revised the New Testament in the Ethiopic, Samaritan, Hebrew, and Syriac, making many useful notes and remarks on difficult passages. He had applied from early youth to mathematics, drawing, and aftronomy, and had acquired fome knowledge of phylic and furgery. His memory was aftonishingly retentive, and his mind vigorous. He was dexterous in negociation, a master of public business, and animated with the display of vanity runs through the whole, and the ap- warmest zeal for the glory of his king and country.

Buck-

Such, at least, is his own representation of his character; and though an impartial judge would probably make considerable abatement for the natural bias of a man drawing his own portrait, yet it cannot be denied, that in personal accomplishments Mr Bruce equalled, if

not exceeded, most of his contemporaries.

Thus accomplished, he could not but be eminently fitted for an attempt fo full of difficulty and danger as what he called the discovery of the sources of the Nile: no one who peruses his account of the expedition, can fail to pay an unfeigned tribute of admiration to his intrepidity, manliness, and uncommon dexterity, in extricating himself out of situations the most dangerous and alarming, in the course of his long and hazardous journey; not to mention his conduct during his refidence in Abyssinia, his behaviour at Masuah, Teawa, and Sennaar, evinces the uncommon vigour of his mind: but it was chiefly during his passage through the Nubian defert that his fortitude, courage, and prudence; appeared to the greatest advantage. Of his learning and fagacity, his delineation of the course of Solomon's fleet fror . Tarshish to Ophir, his account of the cause of the inundations of the Nile, and his comprehensive view of the Abysinian history, afford ample proofs. It must indeed be confessed, that in his account of the inundations of the Nile, as well as in his delineation of the course of Solomon's fleet, he has not the merit of originality; but on both these occasions he has stated the hypothesis which he maintains with greater clearnefs, and supported it with more plaufible arguments, than any other author whose writings have sallen into our hands; and it was furely to his honour, that as foon as he learned that his hypothesis respecting Ophir and Tarshish had been controverted by Dr Doig of Stirling, he earnestly courted the acquaintance of that eminent scholar.

After his return to his own country, he resided mostly at Kinnaird; and till he became corpulent, spent much of his time in the various sports of the field, in which he engaged with great ardour. Though studious in youth, and at all times a stranger to intemperance and diffipation, he read but little in his later years; and feemed to find his chief pleasure in conversation, especially the conversation of well-informed ladies. In his friendships he sometimes appeared to be capricious, attaching himself to men in whose heads and hearts no other person could perceive a charm for a mind like his. Though in his own dealings he was always just and honourable, he was too ready to apprehend unfairness in others, and to express fuch apprehensions with undue warmth. To strangers he was often arrogant, and sometimes insolent; but in his own family he was an affectionate husband, a kind father an agreeable entertainer, and to his fervants a mafter perhaps too indulgent. In conversation, as well as in his writings, he embraced every opportunity of expressing a deep and lively fense of the care of a superintending Providence, without which he was convinced that there could be no fafety in human strength or human foresight. His belief of the Christian religion rested on the surest grounds; and fuch was his veneration for the facred writings, that for some years before his death they seemed to occupy all the time which he gave to study. He read no sermons, however elegant; and diffuaded others from fuch reading. " Read the Bible (faid he), and you will

SUPPL. VOL. I. Part I.

foon perceive the emptinese of the most applauded fermons."

BUCK-WHEAT, a species of Polyganum (see that article Encycl.), was first introduced into Europe about the end of the 15th or the beginning of the 16th century. According to some botanists, who lived at that period, its native country is the northern parts of Asia, whence it was brought to Germany and France, where, about the year 1587, it was the common food of the poor.

A new species of this grain, or, to speak perhaps more properly, a variety of this species, has been for fome time known under the name of Siberian buckwheat, which appears to have confiderable advantages over the former. It was fent from Tartary to St Petersburgh by the German botanists, who travelled thro' that country in the beginning of the prefent century; and it has thence been dispersed over all Europe. Linnæus received the first feeds of it in 1737 from Garber the botanist, and described the plant in his Hortus Cliffertionus. After this it was mentioned by Ammann in 1739: but it must have been earlier known in Germany; for in 1733 it was growing in the garden of Dr Ehrliart at Memmingen In Siberia this plant fows itfelf for four or five years by the grains that drop; but at the end of that period the land becomes fo full of tares that it is choked, and must be sown afresh. Even in the economical gardens of Germany, it is propagated in the fame manner; and in that country it is in some places found growing wild, though it is nowhere cultivated in the neighbourhood. It is not, however, indigenous, otherwife Ehrhart might have raifed it from German feed, which it feems he could not find in 1733. See much curious information concerning this plant in Professor Beckmann's History of Inventions and Disco-

BULAM, or BULAMA, as it is more usually called, forms part of the Archipelago, or cluster of islands, lying on the western or windward coast of Africa, and known by the name of the Bissass or Bissass, which are supposed to have been celebrated by the ancients under the appellation of the Hesperides. It is situated at the mouth of the Rio Grande, in 11° N. Lat. and 15° W. Long. from the meridian of London; and is between seventeen and eighteen leagues long, and from four to five broad.

This island has become an interesting object to the inhabitants of Great Britain, in consequence of its having been purchased in the year 1792 by a society instituted for the same humane purposes with those which gave rise to the Sierra-Leona company (see Sierra-Leona, Encycl.) The Bulam affociation was formed towards the latter end of the year 1791; and they were induced to pitch upon that is at the most eligible tract for their intended colony, in consequence of the stattering description given of its climate, soil, and harbours, by M. Brue, formerly director-general of the French African companies.

The gentlemen originally appointed as trustees for managing the concerns of the affociation at home were, Paul Le Mesurier, M. P.; James Kirkpatrick, Esq; George Hartwell, Esq; Moses Ximenes, Esq; Sir John Riggs Miller, Bart. and David Scott, Esq; M. P; and for establishing the colony, and conducting the affairs of the society abroad, the following gentlemen were no-

minated,

minated, viz. Messer H. H. Dalrymple, John Young, Sir fon, and are highly beneficial, as they purify the air, Bulan, William Halton, Bart. John King, Philip Beaver, Peter and dispel the noxious vapours with which it would Clutterbuck, Nicholas Bayly, Francis Brodie, Charles otherwise abound. Drake, John Paiba, Richard Hancorne, Robert Dobbins, and Isaac Ximenes.

A sum of L. 9000 being quickly subscribed for the establishment of the intended colony, this committee failed from Spithead in three ships on the 11th of April 1792; and landing in due time at Bulama, they purchased that island from the kings of Canabac, who claimed it as their property. They purchased likewise from the kings of Ghinala the neighbouring island Arcas, and the adjacent land on the continent; and thefe feveral purchases being taken possession of in the usual form, a body of fettlers, confilling of 49 men, 13 women, and 25 children, were left at Bulama under the fuperintendence of Mr Beaver, with a temporary fupply o' provisions, stores, plantation-tools, and merchandite, for trading with the neighbouring natives. It is from the dispatches of thefe fettlers, after having lived some time in Bulama, that the following account of the island was drawn up by Mr Johansen.

"The climate, on the whole, may be deemed falubrious, and will become more fo in proportion to the increate of cultivation. The mornings and evenings are temperate and pleasant; the middle of the day is hot, but the fine fea breeze which then, fets in tends greatly to cool and refresh the air. The heat of the sun is not either so excessive or intolerable as has been generally supposed; indeed nature has most admirably adapted our mechanical and physical qualities to the exigencies of different regions; and man, who is the inhabitant of every climate, may, in tome measure, render himself indigenous to every foil. Here the only danger arises from too fudden an exposure to the operation of the vertical rays of the fun, or an excefs of labour; both of which the first fettlers ought most studiously to avoid.

"It appears from Mr Beaver's observations at noon, between the 20th of July 1792, and the 28th of April 1793, that the thermometer, when lowest, was at 74; the medium heat 85; and that it never exceededed 96, except at one time when it rofe to 100, during a calm that occurred in the interval between the north-east breeze in the morning and the fouth-west in the evening of the 19th of February 1793. The difference between the heat of noon and that of the morning and evening is from 20 to 30 degrees. On the 23d of October 1792, hail of the fize of a pin's head fell during two minutes, although not a cloud was to be feen during this phenomenon. The mercury in the thermometer then stood at 85; the wind was at north-east in the morning and fouth-west in the evening.

"Immediately after fun let a dew constantly begins to fall, which induces fome to light a fire in their houses; they at the same time put on warmer clothing. There is little or no twilight; and night and day are nearly equal: the earth has therefore time to cool during twelve hours absence of the sun.

"None of those terrible and destructive hurricanes so frequently experienced in the West Indies are to be met with here. The tornadoes, which arise chiefly from the eastern point of the compals, are but of short duration, feldom lafting above an hour, and may be readily forefeen some time previously to their commencement. They occur at the beginning and close of the wet fea-

"The rains fet in about the latter end of May or the beginning of June, and discontinue in October or November. They do not fall every day, for there is often a confiderable interval of clear weather, during which the atmosphere is beautifully serene; the showers in the first and last month occur but seldom, and are far from being violent; while, on the other hand, they fometimes refemble torrents, more especially towards the middle of the leafon. During the whole of this period, Europeans should, if possible, confine themselves to their habitations, as the rains prove injurious to health, more especially if those exposed to them neglect to wipe their bodies dry, and to change their clothes immediately on their return home. It is deemed prudent also not to dig the earth until the expiration of a month after the return of fair weather, as this is confidered to be unhealthy.

" During the continuance of the dry feafon, a dew falls during the night, in sufficient quantity to answer all the purpofes of vegetation.

" Every stranger is generally here, as well as in the West Indies, subject to a fever or feafoning on his arrival. This is not infectious; it proceeds perhaps from an increased perspiration and a sudden extension of the pores of the human body, in confequence of the heat, by which means it is rendered more liable to imbibe the abundant exhalations that arise from the animal, vegetable, and mineral kingdoms; but even this, slight as it is, might doubtless be avoided by means of a proper regimen, and a short feclusion from the full action of the open air, more especially at noon, and during the evening, until the climate has been rendered familiar.

"Bulama is admirably adapted for all the purposes of an extensive commerce, being not only happily fituated at the mouth of the Rio Grande, but in the vicinity of feveral other navigable rivers; fo that a trade with the internal parts of Africa is thereby greatly facilitated. The landing is remarkably eafy and fafe, there being no furge; the ebb and flow is regular, and there is an increase of 16 feet of water at spring tide. The bay opposite the Great Bulama is adorned with a number of islands, covered with trees, and forms a most excellent harbour, fufficiently capacious to contain the whole navy of Great Britain, which might ride there in fafety. The fettlement in general is well fupplied with water. A number of springs have been lately difcovered in different places; and befides a draw-well in the fort, which was crected for the defence of the colony, there is a fmall stream, which runs into Elewsis Bay, near the new settlement called Hefper Elewsis: this is admirably situated for the supply of thipping.

"The island is beautifully furrounded, and intersperfed with woods: lofty fruit and forest trees, mostly free from underwood and brambles, form a verdant velt, in fome places two or three miles broad, which entirely eneircles it, in fuch a manner as to represent a plantation artificially formed around a park. Within this the fields are regularly divided by trees, to as to refemble the hedge-rows in England. The beach has in fome places the appearance of gravel walks; it is fringed with mangrove trees, which forming a line with the

im.

high-water mark dip their branches into the fea, and thus afford nourithment to the oysters that often adhere to their extremities.

possessing possessing

Several parts of Bulama have been occasionally cultivated by the neighbouring blacks, though they did not

constantly refide on it.

"The land in general rifes gradually towards the middle of the island, where the highest spot is from 60 to 100 teet above the level of the fea. The small hill on which the fort is situated is nearly of the same altitude.

"The foil is abundantly rich and deep; stones do not here impede the labours of the farmer; and indeed none have hitherto been discovered, but a small fort, resembling pieces of ore, which are to be met with on the shore. There are many savannahs or natural meadows, so extensive that the eye can scarcely descry their boundaries. These are admirably adapted for the rearing of stock and seeding of cattle of every kind.

"Cotton, indigo, rice, and coffee, grow spontaneously on this coast; the sugar-cane is indigenous to
many parts of Africa, and might be cultivated here by
the labour of freemen, in equal perfection, and to much
greater advantage, than in the exhausted islands of the
West Indies. All kinds of tropical productions, such
as pine-apples, limes, oranges, grapes, plums, cassada,
guava, Indian wheat, the papaw, water-melon, muskmelon, the pumpkin, tamarind, banana, and numbers of
other delicious truits, also flourish here. The adjoining territories produce many valuable forts of spices,
gums, and materials for dying: all of which, it is but
fair to suppose, might be readily cultivated in a kindred
climate and a congenial soil.

"The neighbouring feas abound with a variety of fish, highly agreeable to the palate. The lion, tyger, jackall, &c. are natives of the continent; but in Bulama no animals have been discovered, the wolf, some buffaloes, a few elephants, and a species of the deer ex-

cepted.

"The woods abound with doves, guinea fowls, and a variety of birds, celebrated for the beauty of their

plumage.

"The natives of this part of Africa, like all favages, are entirely under the dominion of their passions: hence the violence of their attachment to their friends, and the excess of their refentment against their enemies. Their notions of property are very obscure and consused: they have no idea of any right arising from occupancy or improvement. What they want, they either receive or take wherever they may happen to meet with it, and they permit others to do the same. They have been taught by experience that the Europeans will not agree to this: against them therefore they employ every artifice that it is in the power of cunning to suggests.

"The colonists need not fear any attack on the part of the negroes, provided their own conduct be just and peaceable: for Mr Beaver, who was indeed admirably calculated by nature and habit for the station he occupied, could insure both safety and respect when the settlers under him were reduced to four white men, although the neighbouring nations knew that he was in

possession of commodities, for the acquisition of which many of them had become day-labourers. He often kept from twenty to forty gromittos, or black cultivators in pay, at that very period, at about four or five bars (A) each per month. These are easy to be procured, to almost any number that can possibly be wanted.

"Until a fufficient quantity of flock and provisions can be raised in the company's settlements, the adjacent islands will furnish abundance of cattle, hogs, towls, &c. at a very cheap rate. A horse may be purchased at Goree for 11. 10s. a bullock may be had from 12s. to 18s. sterling: provisions of all kinds are equally reasonable. Honey is also to be procured in great plenty, and bees wax may be rendered an advantageous object

of commercial speculation.

"In fhort, the acquifition of Bulama, Arcas, and the adjacent territories, prefents the faire? opportunity of furnishing Europe with many valuable articles that have hitherto been brought from more remote countries, with much greater hazard, and at an increated expence. The intercourse with England is easy, safe, and expeditious; for the voyage may be performed in the space of three or four weeks: and by the terms of the first subscription, a settler on Bulama might purchase 500 acres of land for L.30 sterling; by the terms of the second, which we suppose are the terms at present, he might purchase on the islands of Bulama and Arcas, or on that part of the adjacent coast which was ceded to the society by the kings of Ghinala, 200 acres for L 50 sterling.

"The colonization of Africa opens a noble and extenfive field to nations and to individuals. To people
those fertile territories, despoiled of their inh bitants by
the flave trade; to rear the productions of the climes
between the tropics, by the affishance of free men; to
give ample scope to the industry and exertions of those
who may be inclined to remove from Great Eritain;
and to extend the commerce and the manufactures of
our native country—these are subjects which have excited the attention of the Bulama affociation, and now
claim the affishance of the ingenious, the support of the
rich, and the concurrence and good wishes of all.

BUNTING, is a bird which has been described under its generic name Emberiza (Encycl.); but there is one species, the orange shouldered bunting of Latham, of which M. Vaillant relates some particulars certainly

not unworthy of notice in this place.

"The female of this beautiful bird (fays he) has the fimple colours of the fky-lark, and a fhort horizontal tail, like that of almost all other birds: the male, on the contrary, is wholly black except at the shoulder of the wing, where there is a large red patch; and his tail is long, ample, and vertical, like that of the common cock. But this brilliant plumage and sine vertical tail subsist only during the season of love, which continues fix months. This period over, he lays aside his iplended habiliments, and assumes the more modelt dress of his mate. The most extraordinary circumstance is, that the vertical tail also changes to a horizontal one, and the male so exactly retembles the female, that it is not possible to distinguish them from each other.

"The female has her turn. When fhe reaches a cer-

(A) A bar is about the value of three shillings and sixpence.

Bunting, tain age, and has loft the faculty of propagating the species, she clothes herself for the remainder of her days in the garb which the male had temporarily affumed; her tail, like his at that period, grows long, and, like his also, from horizontal becomes vertical.

"The birds of this species affociate together, live in a fort of republic, and build their nests near to each other. The fociety usually consists of about fourscore females; but whether, by a particular law of nature, more females are produced than males, or for any other reason of which I am ignorant, there are never more than twelve or fifteen males to this number of females,

who have them in common."

According to our author, this transmutation is by no means confined to this particular species of bunting. Many females of the feathered creation, when they grow so old as to cease laying eggs, assume the more Iplendid colours of the male, which they retain during the remainder of their lives. This fact is strikingly perceptible in those species in which the male and female very much differ in colour, as the golden pheafant of China, for instance. In some species, and those not a few, the male alone regularly changes his colour, and assumes once in a year the plumage of the female; so that at a certain period all the birds of that species appear females. "I have in my possession (says our author) specimens of more than fifty of those changing fpecies, in all their transitions from one hue to another; and the change is sometimes so great, that a person would suppose himself to see individuals totally different. A closet-naturalist, for instance, shewed me four birds as fo many different species, and even as not belonging to the fame genus, with which I was well acquainted, and which I knew to be the fame bird, only of different ages."

Such changes as thefe, could they be proved to take place occasionally among domestic fowls, would in some measure account for strange stories of cocks laying eggs, which we have heard related by persons whose general

veracity was never questioned.

BURKE (Edmund), was born in the city of Dublin on the 1st of January 1730. His father was an attorney of confiderable knowledge in his profession, and of extensive practice; and the family from which he fprung was ancient and honourable. He received the rudiments of his classical education under Abraham Shackleton, a Quaker, who kept a private school or academy, as it has been called, at Bellytore, near Carlow, and is faid to have been a very skilful and successful teacher.

Under the tuition of this master Burke devoted himfelf with great ardour, industry, and perseverance, to his studies; and manifested, even from his boyish days, a distinguished superiority over his contemporaries. He was the pride of his preceptor, who prognosticated every thing great from his genius, and who was, in return, treated by his illustrious pupil, for forty years, with respect and gratitude.

From school Burke was sent to Trinity-college, Dublin, where it was afferted by Goldsmith and others his contemporaries, that he displayed no particular eminence in the performance of his exercises. Like Swift, he despised the logic of the schools; and like him too, he devoted his time and his talents to more useful pursuits.

Johnson, though proud of being an Oxonian, did not Burke. much employ himself in academical exercises; and Dryden and Milton, who studied at Cambridge, were neither of them ambitious or college diffinctions. Let not, however, the example of a Burke, a Johnson, a Dryden, or a Milton, seduce into by-paths the ordinary student; for though great genius either finds or makes its own way, common minds must be content to purfue the beaten track. Shakespeare, with very little learning, was the greatest dramatic poet that ever wrote; but how absurd would it be to infer from this fact, that every illiterate man may excel in dramatic poetry?

Whilst at college Burke applied himself with sufficient diligence to those branches of mathematical and physical science which are most subservient to the purpoies of life; and though he neglected the fyllogistic logic of Aristotle, he cultivated the method of induction pointed out by Bacon. Pneumatology, likewise, and ethics, occupied a confiderable portion of his attention; and whilst attending to the acquisition of knowledge, he did not neglect the means of communicating it He fludied rhetoric and the art of composition, as well as logic, physics, history, and moral philosophy; and had at an early period of his life, fays Dr Biffet, planned a. confutation of the metaphyfical theories of Berkeley

and Hume.

For fuch a task as this, we do not think that nature intended him. Through the ever-active mind of Burke ideas feem to have flowed with too great rapidity to permit him to give that patient attention to minute diflinctions, without which it is vain to attempt a confutation of the subtleties of Berkeley and Hume. The ablest antagonist of these two philosophers was remarkable for patient thinking, and even apparent flowness of apprehension; and we have not a doubt, but that if he had possessed the rapidity of thought which characterised Burke, his consutation of Hume and Berkeley, would have been far from conclusive. It might have been equal to the Essay on the Nature and Immutability of Truth, but would not have been what we find it in The Inquiry into the Human Mind on the Principles of Common Sense, and in The Essays on the Intellectual and! Active Powers of Man.

A task much better suited to Burke's talents than: the writing of metaphylical disquisitions on the substratum of body, presented itself to him in the year 1749, and a task which was likewise more immediately useful. At that period one Lucas, a democratic apothecary, wrote a number of very daring papers against government, and acquired by them as great popularity at Dublin as Mr Wilkes atterwards obtained by his North Briton in London. Buske, though a boy, perceived, almost intuitively, the pernicious tendency of such levelling doctrines, and refolved to counteract it. He wrote several essays in the style of Lucas, imitating it. fo exactly as to deceive the public; pursuing his principles to consequences necessarily resulting from them, and shewing at the same time their absurdity and their danger. Thus was his first literary effort, like his last, calculated to guard his country against anarchical inno-

Whilft employed in treasuring up knowledge, which at a future period was to command the admiration of listening senates, he did not neglect the means necessary

to render himself agreeable in the varied intercourse of private life. To the learning of a scholar he added the manners of a gentleman. His company was fought among the gay and the fashionable, for his pleating converfation and early deportment; as much as among the learned, for the force and brilliancy of his genius, and the extent and depth of his knowledge. But though the object of very general regard in his native country, he had hardly any prospect of obtaining in it an independent settlement. He therefore applied, some time after the publication of his letters exposing the doctrines of Lucas, for the professorship of logic, which had then become vacant in the univerfity of Glafgow: but whether that application was made too late, or that the univerfity was unwilling to receive a stranger, certain it is that the vacant chair was filled by another, and that Burke was disappointed of an office in which he was eminently qualified to excel For many years very little attention has been paid in the universities of Scotland, perhaps even too little, to the Aristotelian logic; and the professors, instead of employing their time in the analyfing of fyllogifms, deliver lectures on rhetoric and the principles of composition-lectures which no man was more capable of giving than the unfuccefsful candidate for the professorship in Glasgow.

Disappointment of early views has frequently been the means of future advancement. Had Johnson become master of the Staffordshire school, talents might have been consumed in the tuition of boys which Providence formed for the instruction of men; and had Burke obtained the professorship of logic in Glasgow, he would have been the most eloquent lecturer in that university, instead of the most brilliant speaker in the British senate; but whether his talents might not have been as usefully employed in the university as in the senate, may perhaps be a question, though there can be no question whether they would have invested himself with

an equal blaze of splendour.

Disappointed in Glasgow, he went to London, where he immediately entered himself of the Temple; and as there is reason to believe that he was in straitened circumstances, he submitted to the drudgery of regularly writing for daily, weekly, and monthly publications, essays on general literature and particular politics. The profits arifing from fuch writings were at first small: but they were so necessary to their author, that the intense application which they required gradually impaired his health, till at last a dangerous illness ensued, when he reforted for medical advice to Dr Nugent, a physician whose skill in his profession was equalled only by the benevolence of his heart. The Doctor, confidering that the noise, and various disturbances incidental to chambers, must retard the recovery of his patient, furnished him with apartments in his own house, where the attention of every member of the family contributed more than medicines to the restoration of his health. It was during this period that the amiable manners of Miss Nugent, the Doctor's daughter, made a deep impression on the heart of Burke; and as she could not be infensible to such merit as his, they felt for each other a mutual attachment, and were married foon after his recovery.

Hitherto his mental powers and acquirements were known in their full extent only to his friends and more intimate companions; but they were now made public in his first acknowledged work, intitled, A Vindication Burke. of Natural Society. The object of this performance was to expose the dangerous tendency of Lord Bolingbroke's philosophy. By the admirers of that nobleman his principles were deemed inimical only to revealed religion and national churches, which they would have been glad to see overturned, provided our civil establishment had been preserved; and to the civil establishment. they perceived no danger in the writings of the author of The Patriot King. Mr Burke thought very differently; and endeavoured to convince them, that if his Lordship's philosophy should become general, it would ultimately destroy their rank, their confequence, and their property, and involve the church and state in one common ruin. In his ironical attack upon artificial fociety, he makes use of the same common-place mode of unfair reasoning which his noble antagonist had employed against religion and religious establishments. He argues, from the incidental abuses of political fociety, that political fociety must itself be evil; he goes over every form of civil polity, pointing out its defects in the most forcible language; and, in perfect imitation of the fceptical philosophy, he pulls them all down, one after another, without proposing any thing in their flead. So complete is the irony, that to many not acquainted with fuch disquisitions, he would appear to be feriously inveighing against civil government; and we have actually heard some of the advocates for modern innovation mention this work as a proof how different Mr Burke's opinions in politics once were from what they appear to have been when he wrote his Reflections: on the French Revolution.

The truth, however, is, that there is no inconfiftency between The Vindication of Natural Society and the latest publications of its illustrious author. At the period when that work was published, insidelity had infected only the higher orders of men, and fuch of the lower as had got the rudiments of a liberal education. Of these we believe a single individual was not then to be found, who supposed that society could subfift both without government and without religion; and therefore whilf they laboured to overturn the church, and to prove that Christianity itself is an imposture, they all pretended to be zealously attached to our civil government as established in king, lords, and commons. Except the clergy of the established church, there was no order of men whom they indifcriminately reviled. Hence it was that not Burke only, but Warburton, and almost every other opponent of Lord Bolingbroke, began their detences of revelation, by shewing the indissoluble connection between our civil and ecclesiastical establishments; and all the difference was, that he did, through the medium of the most refined irony, the very fame thing which they had done by lerious reasoning.

Soon after his Vindication of Natural Society, Burke published A Philosophical Enquiry into the Origin of our Ideas of the Sublime and Beautiful; a work which soon made its author universally known and admired, and which has been studied by every English reader of taste. It is therefore needless for us to hazard any opinion either of its general merit or its particular defects. In one of the literary journals of that day, Mr Murphyurged objections against some of its fundamental principles, which, in our opinion, it would be very difficult to answer; whilst Johnson, who was certainly a severe

judge,

Turke. judge, confidered it as a model of philosophical criticifni. "We have (taid he) an example of true critieism in Burke's Essay on the Sublime and Beautiful. There is no great merit in shewing how many plays have ghosts in them, or how this ghost is better than that; you must shew how terror is impressed on the mind."

In consequence of this manifestation of Burke's intellectual powers. his acquaintance was courted by men of diffinguished talents, and, among others, by Johnson and Sir Joshua Reynolds. The literary club, which has been mentioned (Encycl.) in the life of Johnson, was instituted for their entertainment and instruction, and confished at first of Johnson, Burke, Reynolds, Goldsmith, Dr Nugent, Mr Topham Beauclerc, Sir John Hawkins, Mr Chamier, and Mr Bennet Langton, who were all men of letters and general information, though far above the rest stood Burke and Johnson. Of Burke indeed, Johnson declared, upon all occasions, that he was the greatest man living; whilft Burke, on a very solemn occasion, said of Johnson, "He has made a chasm, which not only nothing can fill up, but which nothing has a tendency to fill up. Johnson is dead. Let us go to the next best—I here is nobody—No man can be faid to put you in mind of Johnson." Nor was the epinion which these two illustrious men held of each other's powers peculiar to themselves alone: all the members of the club observed, that, in colloquial talents, they were nearly matched, and that Johnson never discoursed with such animation and energy as when his powers were called forth by those of Burke.

Some years before the institution of this club, Burke, who had devoted much of his time to the study of hiftory and politics, proposed to Mr Dodsley, an eminent bookseller, a plan of an Annual Register of the civil, political, and literary transactions of the times; and the proposal being acceded to, the work was begun and carried on for many years, either by Burke himself, or under his immediate inspection. It bears indeed internal marks of his genius, his learning, and his candour, being by much the most elegant and impartial periodical history which has perhaps appeared in any age or nation. Even when the heat of opposition made him, in his speeches, sometimes misrepresent the conduct of administration, the Annual Register, under his management, continued to render justice to all parties.

He still continued to write occasionally political effavs for other publications than the Annual Register; and some of these essays in the Public Advertiser having attracted the notice of the Marquis of Rockingham, that nobleman fought the acquaintance of their author. It was in the year 1765 that the first interview took place between them; and the Marquis, who was then at the head of the treasury, offering to make Burke his own fecretary, the offer was readily accepted. On this occasion he gave a remarkable proof of difinterestedness and delicate integrity. Through the influence of Mr Hamilton, known by the appellation of Single-Speech Hamilton, and long suspected to be the author of Junius's Letters, he had some time before obtained a penfion of L. 300 a year on the Irish establishment; but this pension he now thought it incumbent upon him to refign, because he had connected himself with a party opposite in many things to the party whose measures were supported by his friend.

During the Rockingham administration he was cho- Burke, fen member of parliament for the borough of Wendover in the county of Bucks; and he prepared himself for becoming a public speaker, by studying, still more closely than he had yet done, history, poetry, and philosophy; and by floring, his mind with facts, images, reafonings, and tentiments. He paid great attention likewife to parliementary usage; and was at much pains to become acquainted with old records, patents, and precedents, so as to render himself complete master of the bufiness of office. That he might communicate without embarraffment the knowledge which he had thus laboriously acquired, he frequented, with many other men of eminence, the Robin Hood Society, where he practifed the replies and contentions of eloquence; and to acquire a graceful action, with the proper management of his voice, he was a very diligent observer of Garric in Drury Lane theatre. He procured his feat in 1765, and in the ensuing session delivered his maiden speech; which was fuch a display of eloquence as excited the admiration of the House, and drew very high praise from its most distinguished member Mr Pitt, afterwards Earl of Chatham.

The principal objects which engaged the attention of the Rockingham administration were the ferments in America, which was then in a state little short of rebellion, on account of the famous stamp act. Parliament was divided in opinion respecting that measure. Whilft Mr Grenville and his party (under whose aufpices the stamp act had passed into a law) were for enforcing obedience to it by coercive measures, Mr Pitt and his followers denied that the parliament of Great Britain had a right to tax the Americans; and the marquis of Rockingham, who was hardly able to carry any measure in opposition to both these parties, had to confider, on this occasion, whose sentiments he would adopt. By the advice, it is taid, of Mr Burke, he chose a middle course between the two opposite extremes. To gratify the Americans, he repealed the stamp-act; and to vindicate the honour of Britain, he got a law passed declaratory of her right to legislate for America in taxation as in every other cate.

This measure, whoever was its author, was certainly not the offspring either of wisdom or vigour. If the mother country had a right to legislate in all cases for America, obedience to the stamp-act should certainly have been enforced; and the ministry which relinquished an acknowledged right, to gratify the factious difposition of distant colonies, was obviously unfit to guide the helm of a great empire. Lord Rockingham and his friends were accordingly dismissed from office; and a new administration was formed under the auspices of Mr Pitt, now created earl of Chatham.

Burke, in the mean time, wrote in defence of the party with which he was connected; and affumed great credit to it for composing the distractions of the British empire by the repeal of the American stamp act, whilst the constitutional superiority of Great Britain was preferved by the act for fecuring the dependence of the colonies. After defending his friends, he proceeds to attack those who had succeeded them in office. Of Lord Chatham he fays-" He has once more deigned to take the reins of government into his own hand, and will, no doubt, drive with his wonted fpeed, and raife a deal of dust around him. His horses are all Burke. matched to his mind; but as some of them are young anthors, they have been given to Burke, to his brother Burke. and skittish, it is faid he has adopted the new contrivance lately exhibited by Sir Francis Delaval on Westminster bridge: whenever they begin to snort and toss up their heads, he touches the spring, throws them loofe, and away they go, leaving his lordship fafe and fnuz, and as much at his ease as if he sat on a woolpack."

The letter, of which this is an extract, was printed in the Public Advertifer; and is faid to have contributed, in no small degree, to lessen the popularity of the illustrious statesman against whom it was written. The ministry, indeed, which he had formed, confifted of very heterogeneous materials, and was not heartily approved of by the nation. It therefore foon fell in pieces by its own discord, and Lord Chatham retired

The parliament being diffolved in 1768, Burke was re elected for Wendover, and took his feat, when the house met, in November. The duke of Grafton was now prime minister, and was opposed by two powerful parties in parliament; that of the marquis of Rockingham, and that of which Mr Grenville was confidered as the leader. These two parties, however, differed widely between themselves. Mr Grenville had published a pamphlet, intitled, The Present State of the Nation; in which he very ably vindicated his own measures, and of course condemned the measures of those who had succeeded him; and Burke replied to him, with greater eloquence, but, perhaps, with less of argument, in a tract, intitled Observations on the Present State of the Nation, in which he makes a very high panegyric on his own patron, and the connections of the party, and animadverts with cutting severity on their fuccessors in

About this period commenced the national frenzy which was excited by the expulsion of Wilkes from the house of commons, for having printed and published a feditious libel, and three obscene and impious libels. In the controverly to which this transaction gave rife, Burke and Johnson took opposite sides. Johnson, in his False Alarm, contends, with great ability, that the expulsion of a member from the house of commons for the commission of a crime, amounts to a disqualification of that member from fitting in the parliament from which he is expelled; whilft Burke, though he disapproved of the conduct of Wilkes as much as his friend, laboured to prove, that nothing but an act of the legislature can difqualify any person from sitting in parliament who is regularly chosen, by a majority of electors, to fill a vacant feat. It does not appear that this difference of opinion produced the smallest abatement of mutual regard between him and Johnson. They both attended the weekly club, and were as much pleased with each other as formerly.

The proceedings of the Grafton administration, respecting Wilkes and other subjects, gave rise to the celebrated Letters of Junius. That thole compositions were, in clearnels, neatness, and precision of style, infinitely superior to perhaps every other series of newspaper invectives, has never been controverted; and that they display a vast extent of historical and political information, is known to all who are not themselves ftrangers to the hittory of this kingdom. Unclaimed by any author, and superior to the productions of most

Richard, a man likewise of very bright talents, to Mr Hamilton, and to Lord George Germaine. We flould hardly hesitate to adopt the opinion of those who aferibe them to Burke, had he not disavowed them to his friend Johnson. "I should have believed Burke to be Junius (said Johnson), because I know no man but Burke who is capable of writing these letters; but Burke spontaneously denied it to me. The case would have been different had I affeed him if he was the author. A man may think he has a right to deny when fo questioned as to an anonymous publication." The difference between the ftyle of these letters and that of Burke's acknowledged writings, would have had no weight with us; because such was his command of language, that he could affume, and occasionally did as2 fume, any flyle which he chofe to imitate. He had already fo closely imitated the very different styles of Lucas and Bolingbroke as to deceive the public; and what was to hinder him from imitating the flyle of Lord George Germaine, which certainly has a strong refemblance to that of Junius? We think, however, with Johnson, that his Spontaneous disavorwal of these letters ought to be held as sufficient proof that he was not their author.

Burke had now gotten a very pleafant villa near Beaconsfield in Buckinghamshire; and being one of the freeholders of the county, he drew up a petition to the king, complaining of the conduct of the house of commons respecting the Middlefex election, and praying for a diffolution of the parliament. The petition, tho explicit and firm, was temperate and decorous, and as unlike to one on the same subject from the livery of London, as the principles of a moderate Whig are to those of a turbulent democrate.

About this period he stated very clearly his own political principles in a pamphlet intitled, "Thoughts on the Causes of the Present Discontents;" and his plan for removing these discontents had not a grain of democracy in its composition. He proposed to place the government in the hands of an open arithocracy of talents, virtue, property, and rank, combined together on avowed principles, and supported by the approbation and confidence of the people; and the ariffocracy which he thought fitted for this great trust, was a combination of those Whig families which had most powerfully supported the revolution and confequent establishments. He expressed, in strong terms, his disapprobation of any change in the constitution and duration of parliament; and declared himself as averse from an administration which should have no other support than popular favour, as from one brought forward merely by the influence of the court.

In this plan there is not that wisdom or liberality which might have been expected from a man of Burke's cultivated mind and extensive reading. The Whigs, when in power, had been as venal as the Torics; and the imprisonment of Lord Oxford, the banishment of Atterbury bishop of Rochester, and the resolution of the house of commons to fit for seven years, when it had been chosen by its constituents for no more than three, were certainly greater violations of the constitution than the disqualification of Wilkes, or any other measure that had been carried by the court during the administrations of Grenville and the duke of Graftons

Burke

Burke.

no republican; but every fentence of it breathed the

spirit of party.

Lord North was now prime minister; and in order to tranquillize America, he proposed, in the beginning of his administration, to repeal the obnoxious laws of his predecessors in office, and to referve the duty on tea merely to maintain the authority of parliament. The consequences of this conduct we have detailed elsewhere (fee Britain, Encycl.); and they are too well known to all our readers. The part which Burke acted during his administration will not, in our opinion, admit of any plaulible defence. It was not indeed the part of a democrate, but of a man determined to oppose every measure of those in power. In the beginning of the contest, he certainly displayed more wildom and patriotism than the minister; for, without entering directly into the question Whether the mother-country had or had not a right to tax the colonies? he contented himself with warning the house against dangerous innovations. "The Americans (faid he) have been very serviceable to Britain under the old system: do not, therefore, let us enter rashly upon new measures. Our commercial interests have been hitherto greatly promoted by our friendly intercourse with the colonies; do not let us endanger possession for contingency; do not let us substitute untried theories for a system experimentally afcertained to be useful."

This was undoubtedly found reasoning, and everyway becoming a lover of his country: but his continued opposition to government, after all Europe had leagued against Great Britain, was a conduct which will admit of no vindication, and for which the only poslible apology must be found in that ardour of temper which made his friend Hamilton fay, on another occasion, "Whatever opinion Burke, from any motive, supports, fo ductile is his imagination, that he foon conceives it to be right." In his most violent opposition, however, though his expressions were often extravagant and indecent, he never for a moment gave his support to the metaphyfical doctrine of the imprescriptible rights of man, or to the actual innovations which fome meant to introduce on the basis of that doctrine. His upright mind was indeed fufficiently guarded against these novelties by what he had observed in France during the year 1772. Whilst he remained in that country, his literary and political eminence made him courted by all the anti-monarchical and infidel philosophers of the time; and in the religious scepticism and political theories of Voltaire, Helvetius, Rouseau, and D'Alembert, he saw, even at that period, the probable overthrow of religion and government. His fentiments on this subject he took occasion, immediately on his return, to communicate to the house of commons; and to point out the conspiracy of atheism to the watchful policy of every government. He professed, that he was not over fond of calling in the aid of the fecular arm to suppress doctrines and opinions; but he recommended a grand alliance among all believers against those ministers of rebellious darknefs, who were endeavouring to shake all the works of God established in beauty and in order.

The American war proving unsuccessful, though Great Britain never made a more glorious stand, Lord North and his friends retired from office; and, in February 1782, a new ministry was formed, at the head

Burke shewed himself in this publication to be indeed of which was placed the marquis of Rockingham; Lord Shelburne and Mr Fox were the secretaries of state; and Mr Burke, who was appointed pay-master to the forces, exulted, rather childifuly, in the house of commons, on the happiness which was to accrue, both to the king and to the people, from the able and upright conduct of the new ministers. The time in which the greater part of them continued in office was too fhort to permit them to do either much good or much evil.

On the 1st of July the marquis of Rockingham died; and the earl of Shelburne being placed at the head of the treasury, Fox and Burke refigned in difgust, and, to the astonishment of the nation, formed the famous coalition with Lord North, whose measures they had fo long, and fo vehmently, opposed. In the coalition of North and Burke there would have been nothing wonderful. In the intercourse of private life, these two statesmen had always met on terms of friendship and mutual regard; they had the same ideas of the excellence of the constitution, and the same aversion to innovation under the name of reform; even their fludies and amusements were very similar, being both men of taste and classical learning; and though Burke opposed the taxation of America by the British parliament, his opposition proceeded rather from motives of prudence and expediency than from any fettled conviction that the measure was unconstitutional. the political enmity of Fox and North had proceeded, not only to personal abuse, but to professions of mutual abhorrence; and perhaps there was hardly an unprejudiced person in the kingdom who entertained not sufpicions, that the unexpected union of fuch enemies was cemented by a principle less pure than patriotiim.

Mr Pitt was now chancellor of the exchequer; and when he announced to the house of commons the peace which was concluded in January 1783, he found the terms on which it had been made feverely condemned by North, Fox, Burke, and all their friends. The cenfure passed on it by Lord North and his followers was perfectly confiftent with their former conduct, and with the opinions which they had uniformly maintained; but it was with no good grace that Fox and Burke, who had offered an unconditional peace to the Dutch, and so frequently proposed to recognize the independence of America, condemned the peace which had been concluded by Lord Shelburne. On this, as on many other occasions, they acted, not as enlightened politicians, but as the rancorous leaders of a party.

In consequence of a vote of censure passed by the commons, the ministers refigned their employments, and were fucceeded by the duke of Portland, Lord North, Mr Fox, Mr Burke, and their friends. Burke had his former employment of paymafter to the forces; Lord North and Mr Fox were secretaries of state, and the duke of Portland was first lord of the treasury. To many persons this ministry had the appearance of greater strength than any that had governed the kingdom fince the time of Sir Robert Walpole; but its duration was not longer than that of the preceding. On the 18th of November, Mr Fox introduced his famous India-bill, into the merits of which it is foreign from our purpole to enter: fuffice it to fay, that after being strongly supported by Burke, and ably opposed by Pitt and Dundas, it passed the house of commons by a very great majority; but was lost in the house of peers,

arke, and viewed by the king in fuch a light, that he determined on an entire change of administration.

Mr Pitt was now placed at the head of the treafury, where he has remained ever fince, notwithstanding the violent and powerful opposition which he met with at first from North and Fox and their coalesced friends: the voice of the nation has been on his fide; and that voice will always drown the bellowings of patriotism.

The principal events in which Burke fignalized himfelf, fince the year 1784, were the trial of Hastings, the deliberations of the house on the proposed regency during the lamented illuefs of the king, and the French revolution; and on each of these occasions he displayed talents which altonished the nation. He has, indeed, been feverely blamed for the pertinacity with which he profecuted Mr Haftings, and his conduct has been attributed to very unworthy motives; but of this there is neither proof nor probability. The temperament of him mind was fuch, that, into whatever measure he entered, he entered with a degree of ardour of which cooler heads can hardly form a conception. Burke was but one member of a committee which found, or thought it found, evidences of the guilt of Hastings; and, in forming his opinion, it is little likely that he should have been biaffed by interest or resentment, whose delicate sense of rectitude would not permit him to retain a pension when he could no longer support the party of that friend who had obtained it for him.

When the establishment of a regency was thought necessary, he took the part, as it was called, of the prince of Wales, in opposition to the plan proposed by Lord Thurlow and the minister; and we doubt not but he was astuated by the purest principles: but the language which he used in the house was vehement, and fome of his expressions were highly indecent. Our regard for his memory makes us wish to forget them.

Soon after the recovery of the king, the attention of Burke was attracted to the most momentous event of modern times; -an event which has convulfed all Europe, and of which, from the very first, his fagacity forefaw the consequences. Many of his friends in parliament, as well as numbers of wife and good men out of it, augured, from the meeting of the states-general of France, great benefit to that nation, of which the government was confidered as despotic and oppressive: and some were fanguine enough to prognosticate a new and happy order of things to all the nations connected with France, when its government should become more free. Burke thought very differently: He was well acquainted with the genius of the French people, and with the principles of those philosophers, as they called themselves, by whom a total revolution in church and state had long been projected; and from the commencement of their career in the constituent assembly, when they established, as the foundation of all legal government, the metaphyfical doctrine of the rights of man, he predicted that torrent of anarchy and irreligion which they have fince attempted to pour over all Europe. Fox and some of the other leading men in opposition affected to confider this as a vain fear; and a coolness took place between them and Burke, though they still acted together in parliament. At last, perceiving the French doctrines of liberty and equality, and atheifm, spreading through this nation, not only among those who had talents for fuch disquisitions, but in clubs and SUPPL. VOL. I. Part I.

focieties, of which the members could be no judges of Burke. metaphysical reasonings, he expressed his apprehension of the consequences in the house of commons. This brought on a violent altercation between him and Fox, who was supported by Sheridan; and a rupture took place between these old friends which was never healed. He no more attended the meetings of the opposition members; and in 1790 he published his celebrated Reflections on the French Revolution.

By the friends of government this work was admired as the most seasonable, as well as one of the ablest, defences of the British constitution that ever was written; whilft Fox and his friends, with the great body of English diffenters, though they admitted it to be the offfpring of uncommon genius, affected to confider it as declamatory rather than argumentative, and as inconfistent with the principles which its author had hitherto uniformly maintained. Many answers were written to it; of which the most conspicuous were Vindicia Gallica by Mr Mac Intosh, and The Rights of Man by Thomas Paine. To these Burke deigned not to make a direct reply. He vindicated his general principles, as well as some of his particular reasonings, in A Letter to a Member of the National Assembly; and he very completely evinced the confidency of his principles in his Appeal

from the New to the Old Whigs.

Of this great work, for great it undoubtedly is, the merits as well as the demerits have been much exaggerated; and some have made it a question, Whether it has on the whole been productive of good or of harm? By the enemies of the author, it is represented as having given rife to the spirit of discontent, by exciting fuch writers as Paine and his adherents, who, but for the provocation given by The Reflections, might have remained in filence and obscurity. This was from the first a very improbable supposition; for the spirit of democracy has at all times been restless: but since the appearance of Professor Robison's Proofs of a Conspiracy, and Barruel's History of Jacobinism, it must be known to every reader to be a supposition contrary to fact. The conspirators were busy long before Burke wrote his Reflections; and the friends of order and religion are his debtors, for having fo forcibly roused them from their slumber, and put them on their guard. With respect to composition, it is certainly neither so energetic nor fo argumentative as the political tracts of Johnson, to which some have affected to consider it as superior; but it is more poetical, gives scope for a greater display of the knowledge of human nature; and being written on a more interesting subject, it has had a much greater number of readers than those unrivalled pieces of political controversy.

Burke being now affociated with Mr Pitt, continued to write from time to time memorials and remarks on the state of France, and the alliance that was formed against the new order of things in that distracted country, of which some have been published since his death; and having resolved to quit the buffle of public life as foon as the trial of Mr Haftings should be concluded, he vacated his feat when that gentleman was acquitted. and retired to his villa at Beaconsfield, where on the 2d of August 1794 he met with a heavy domestic loss in the death of his only fon. In the beginning of the same year he had lost his brother Richard, whom he tenderly loved: but though this reiterated stroke of

Burke. death deeply affected him, it never relaxed the vigour fion, Johnson alone of all his contemporaries could be Burke, of his mind, nor lessened the interest which he took in

the public weal.

In this retreat, while he was labouring for the good of all around him, he was disturbed by a very unprovoked attack upon his character by some distinguished speakers in the house of peers Soon after the death of his son the king was graciously pleased to bestow a pension on him and Mrs Burke; and this those noble lords were pleased to represent as the reward of what they termed the change of his principles and the defertion of his friends. The injustice of this charge must be obvious to every impartial mind, fince the penfion was given after he had retired from parliament, and could not by his eloquence either support the ministry or gall the opposition. He was not a man to submit tamely to such an insult. He published a letter on the occasion, addressed to a noble lord (Earl Fitzwilliam), in which he repels the attack on his character, and retaliates on those by whom it was made, in terms of fuch eloquent and keen farcasm, as will be read with admiration as long as the language of the letter shall be understood.

Burke having employed every effort which benevolence and wisdom could devise to stimulate civilized governments to unite in opposition to the impiety and anarchy of France, laboured likewise in private to relieve those who had suffered exile and proscription from the direful system. Through his influence a school was established in his neighbourhood for the education of those whose parents, for their adherence to principle, were rendered unable to afford to their children useful instruction; and that school, which on his deathbed he recommended to Mr Pitt, continues to flourish under

his powerful protection.

When the appearance of melioration in the principles and government of France induced our fovereign to make overtures of peace to the French directory, Burke resumed his pen; and in a series of letters, intitled, Thoughts on the Prospect of a Regicide Peace, displayed a force of genius which is certainly not furpaffed, and perhaps not equalled, even in his far famed Reflections on the French Revolution. This was his last work, and was confidered by himself as in its nature testamen-

From the beginning of June 1797 his health rapidly declined; but his understanding exerted itself with undiminished force and uncontracted range; and his difpositions retained all their amiable sweetness. On the 7th of July, when the French revolution was mentioned, he spoke with pleasure of the conscious rectitude of his own intentions in what he had done and written respecting it; intreated those about him to believe, that if any unguarded expression of his on the subject had offended any of his former friends, no offence was by him intended; and he declared his unfeigned forgiveness of all who had on account of his writings, or for any other cause, endeavoured to do him an injury. On the day following he defired to be carried to another room; and whilst one of his friends, assisted by some servants, was complying with his request, Mr Burke faintly uttering, "God bless you," fell back and expired in the 68th year of his age.

From this detail, we trust that our readers are already sufficiently acquainted with his general character. In mon for them to make their children get by heart the

confidered as his rival; and, like that great man, he took every opportunity, especially during his last illness, to declare his unshaken belief of the Christian religion, his veneration for fincere Christians of all perfuations, and his own preference of the church of England. On the worship of that church he had indeed through the whole of his life been a regular and devout attendant; and the tears which the poor, in the neighbourhood of his villa, shed at his funeral, gave sufficient evidence that his faith had been productive of charity. In his public conduct, the irritability of his temper, and the ardour of his imagination, fometimes hurried him into the exceffes of a mere party-man; but we believe that his great religious and political principles never varied. He has himself characterised his public conduct in the conclusion of his Reslections on the French Revolution, when he fays, that "they come from one who has been no tool of power, no flatterer of greatness, and who in his last acts does not wish to belie the tenor of his life; from one who wishes to preserve confistency, but who would preserve consistency by varying his means to secure the unity of his end; and when the equipoise of the veffel in which he fails may be endangered by overloading it upon one fide, is defirous of carrying the fmall weight of his reasons to that which may preserve the equipoife."

BURNS (Robert), was a native of Ayrfhire, one of the western counties of Scotland. He was the son of humble parents; and his father paffed through life in the condition of a hired labourer, or of a small farmer. Even in this fituation, however, it was not hard for him to fend his children to the parish school, to receive the ordinary instruction in reading, writing, arithmetic, and the principles of religion. By this course of education young Robert profited to a degree that might have encouraged his friends to destine him to one of the liberal professions, had not his father's poverty made it necessary to remove him from school, as soon as he had grown up, to earn for himfelf the means of support

as a hired ploughboy or shepherd.

The expence of education in the parish-schools of Scotland is fo fmall, that hardly any parents who are able to labour want the means of giving to their children at least such education as young Burns received. From the spring labours of a ploughboy, from the fummer employment of a shepherd, the peasant-youth often returns for a few months, eagerly to purfue his

education at the parish-school.

It was so with Burns; he returned from labour to learning, and from learning went again to labour, till his mind began to open to the charms of tafte and knowledge; till he began to feel a paffion for books, and for the subjects of books, which was to give a colour to the whole thread of his future life. On nature he foon began to gaze with new difcernment and with new enthuliasm: his mind's eye opened to perceive affeeting beauty and fublimity, where, by the mere groß peasant, there was nought to be seen but water, earth, and fky-but animals, plants, and foil.

What might perhaps first contribute to dispose his mind to poetical efforts, is one particular in the devotional piety of the Scottish peasantry; it is still comgenius, variety of knowledge, and readiness of expres. Pfalms of David, in that version of homely rhymes

which is used in their churches. In the morning and were known to him; contemplating the aspect of na-Burns. in the evening of every day, or at least on the evening of every Saturday and Sunday, these Pfalms are sung in folemn family devotion, a chapter of the Bible is read, and extemporary prayer is fervently uttered. The whole books of the Sacred Scriptures are thus continually in the hands of almost every peafant. And it is impossible that there should not be occasionally some fouls among them, awakened to the divine emotions of genius by that rich affemblage which those books prelent, of almost all that is interesting in incidents, or picturesque in imagery, or affectingly sublime or tender in fentiments and character. It is impossible that those rude thymes, and the simple artless music with which they are accompanied, should not occasionally excite some ear to a fond perception of the melody of verse. That Burns had felt these impulses, will appear undeniably certain to whoever shall carefully peruse his Cottar's Saturday's Night; or shall remark, with nice obfervation, the various fragments of Scripture fentiment, of Scripture imagery, of Scripture language, which are fcattered throughout his works.

Still more interesting to the young peafantry are those ancient ballads of love and war, of which a great number are, in the fouth of Scotland, yet popularly known, and often fung by the rustic maid or matron at her spinning wheel. They are listened to with ravished ears by old and young. Their rude melody; that mingled curiofity and awe which are naturally excited by the very idea of their antiquity; the exquifitely tender and natural complaints fometimes poured forth in them; the gallant deeds of knightly heroifm, which they fometimes celebrate; their wild tales of demons, ghosts, and fairies, in whose existence superstition alone has believed; the manners which they represent; the obsolete, yet picturesque and expressive, language in which they are often clothed-give them wonderful power to transport every imagination, and to agitate every heart. To the foul of Burns they were like a happy breeze touching the wires of an Æolian harp, and calling forth the most ravishing melody.

Beside all this, the Gentle Shepherd, and the other poems of Allan Ramfay, have long been highly popular in Scotland. They fell early into the hands of Burns; and while the fond applause which they received drew his emulation, they presented to him likewife treasures of phraseology and models of versification. He got acquainted at the fame time with the poetry of Robert Ferguson, written chiefly in the Scottish dialect, and exhibiting many specimens of uncommon poetical excellence. The Seasons of Thomson too, the Grave of Blair, the far-famed Elegy of Gray, the Paradife Loft of Milton, perhaps the Minstrel of Beattie, were fo commonly read, even among those with whom Burns would naturally affociate, that poetical curiosity, although even less ardent than his, could in fuch circumstances have little difficulty in procuring

With fuch means to give his imagination a poetical Burns gradually became a poet. He was not, however, one of those forward children who, from a mistaken impulse, begin prematurely to write and to rhyme, and hence never attain to excellence. Converting familiarly for a long while with the works of those poets who

ture in a district which exhibits an uncommon affemblage of the beautiful and the ruggedly grand, of the cultivated and the wild; looking upon human life with an eye quick and keen, to remark as well the stronger and leading, as the nicer and fubordinate, features of character; to discriminate the generous, the honourable, the manly, in conduct, from the ridiculous, the base, and the mean-he was distinguished among his fellows for extraordinary intelligence, good fenfe, and penetration, long before others, or perhaps even himtelf, suspected him to be capable of writing verses. His mind was mature, and well stored with such knowledge as lay within his fearch: he had made himfelf mafter of powers of language, fuperior to those of almost any former writer in the Scottish dialect, before he conceived the idea of furpassing Ramsay and Ferguson.

Hitherto he had converfed intimately only with peafants on his own level; but having got admission into the fraternity of free masons, he had the fortune, whether good or bad, to attract in the lodges the notice of gentlemen better qualified than his more youthful companions to call forth the powers of his mind, and to show him that he was indeed a poet. A masonic fong, a fatirical epigram, a rhyming epiftle to a friend, attempted with fuccefs, taught him to know his own powers, and gave him confidence to try talks more arduous, and which should command still higher bursts of applause.

The annual celebration of the facrament of the Lord's Supper, in the rural parishes of Scotland, has much in it of those old popish festivals, in which superstition, traffic, and amusement, used to be frangely intermingled. Burns faw, and feized in it one of the happiest of all subjects, to afford fcope for the display of that strong and piercing fagacity by which he could almost intuitively diflinguish the reasonable from the absurd, and the becoming from the ridiculous; of that picturelque power of fancy, which enabled him to represent scenes, and perfons, and groupes, and looks, attitude, and gestures, in a manner almost as lively and impressive, even in words, as if all the artifices and energies of the pencil had been employed; of that knowledge which he had necessarily acquired of the manners, passions, and prejudices of the ruftics around him, of whatever was ridiculous, no lefs than of whatever was affectingly beautiful in rural

A thousand prejudices of Popish, and perhaps too of ruder Pagan fuperflition, have from time immemorial been connected in the minds of the Scottish peasantry, with the annual recurrence of the Eve of the Festival of all the Saints or Halloween. 'Thefe were all intimate. ly known to Burns, and had made a powerful impreffion upon his imagination and feelings. He chose them for the fubject of a poem, and produced a piece which is almost to frenzy the delight of those who are best acquainted with its fubject; and which will not fail to preserve the memory of the prejudices and usages which it describes, when they shall perhaps have ceased to give bias, and to favour the culture of his tafte and genius, one merry evening in the year to the cottage fire-

> The fimple joys, the honest love, the fincere friendthip, the ardent devotion of the cottage; whatever in the more solemn part of the rustic's life is humble and artless, without being mean or unfeemly -or tender and dignified,

unnatural, buskined pathos, had deeply impressed the imagination of the rifing poet; had, in fome fort, wrought itself into the very texture of the fibres of his foul. He tried to express in verse what he most tenderly felt, what he most enthusiastically imagined; and

produced the Cottar's Saturday's Night.

These pieces, the true effusions of genius, informed by reading and observation, and prompted by its own native ardour, as well as by friendly applause, were foon handed about among the most discerning of Burns's acquaintance; and were by every new reader perufed and reperused, with an eagerness of delight and approbation which would not fuffer their author long to withhold them from the press. A subscription was proposed, was earnestly promoted by some gentlemen, who were glad to interest themselves in behalf of such signal poetical merit; was foon crowded with the names of a confiderable number of the inhabitants of Ayrshire, who in the proffered purchase sought not less to gratify their own passion for Scottish poefy, than to encourage the wonderful ploughman. At Kilmarnock were the poems of Burns for the first time printed. The whole edition was quickly distributed over the country.

It is hardly possible to express with what eager admiration and delight they were everywhere received .-They eminently possessed all those qualities which the most invariably contribute to render any literary work quickly and permanently popular. They were written in a phraseology, of which all the powers were univerfally felt; and which being at once antique, familiar, and now rarely written, was hence fitted to ferve all the dignified and picturesque uses of poetry, without making it unintelligible. The imagery, the fentiments, were at once faithfully natural, and irrefiltibly impressive and interesting. Those topics of fatire and scandal in which the ruftic delights; that humorous imitation of character, and that witty affociation of ideas familiar and striking, yet not naturally allied to one another, which has force to shake his sides with laughter; those fancies of fuperstition, at which he still wonders and trembles; those affecting sentiments and images of true religion, which are at once dear and awful to his heart, were all represented by Burns with all a poet's magic power. Old and young, high and low, grave and gay, learned or ignorant, all were alike delighted, agitated, transported.

In the mean time, some few copies of these fascinating poems found their way to Edinburgh; and having been read to Dr Blacklock, they obtained his warmest approbation. In the beginning of the winter 1786-7 Burns went to Edinburgh, where he was received by Dr Blacklock with the most flattering kindness, and introduced to every man of generofity and tafte among that good man's friends. Multitudes now vied with each other in patronizing the rustic poet. Those who possessed at once true taste and ardent philanthropy were foon earnestly united in his praise: they who were disposed to favour any good thing belonging to Scotland, purely because it was Scottish, gladly joined the cry; those who had hearts and understanding to be charmed, without knowing why, when they faw their native customs, manners, and language, made the sub-

dignified, without aspiring to slilted grandeur-or to voice of feeling which struggled to declare itself for Burns. Burns: for the diffipated, the licentious, the malignant wits, and the freethinkers, he was fo unfortunate as to have fatire, and obscenity, and ridicule of things facred, fufficient to captivate their fancies; even for the pious he had passages in which the inspired language of devotion might feem to come mended from his pen.

Thus did Burns, ere he had been many weeks in Edinburgh, find himself the object of universal curiofity, favour, admiration, and fondness. He was fought after, courted with attentions the most respectful and assiduous, feasted, flattered, careffed, treated by all ranks as the first boast of his country, whom it was scarcely posfible to honour and reward to a degree equal to his merits. In comparison with the general favour which now promifed to more than crown his most fanguine hopes, it could hardly be called praise at all which he

had obtained in Ayrshire.

In this posture of our poet's affairs a new edition of his poems was earneftly called for. He fold the copyright for one hundred pounds; but his friends at the fame time fuggested, and actively promoted, a subscription for an edition, to be published for the benefit of the author, ere the bookseller's right should commence. Those gentlemen who had formerly entertained the public of Edinburgh with the periodical publication of the papers of the Mirror, having again combined their talents in producing the Lounger, were at this time about to conclude this last feries of papers; yet before the Lounger relinquished his pen, he dedicated a number to a commendatory criticism of the poems of the Ayıshire

The fubscription papers were rapidly filled; and it was supposed that the poet might derive from the subfcription and the fale of his copy-right a clear profit of

at least 700 pounds.

The conversation of even the most eminent authors is often found to be so unequal to the same of their writings, that he who reads with admiration can liften with none but fentiments of the most profound contempt. But the conversation of Burns was in comparison with the formal and exterior circumstances of his education, perhaps even more wonderful than his poetry. He affected no fost air or graceful motions of politeness, which might have ill accorded with the ruftic plainness of his native manners. Conscious superiority of mind taught him to affociate with the great, the learned, and the gay, without being overawed into any fuch bashfulnels as might have made him confused in thought, or hefitating in elocution. He possessed withal an extraordinary share of plain common sense or mother-wit, which prevented him from obtruding upon persons, of whatever rank with whom he was admitted to converse, any of those effusions of vanity, envy, or self-conceit, in which authors are exceedingly apt to indulge, who have lived remote from the general practice of life, and whose minds have been almost exclusively confined to contemplate their own studies and their own works. In convertation he displayed a fort of intuitive quickness and rectitude of judgment upon every subject that arose. The fenfibility of his heart, and the vivacity of his fancy, gave a rich colouring to whatever reasoning he was disposed to advance; and his language in conversation jects and the materials of poefy, could not suppress that was not at all less happy than in his writings. For these

thefe reasons, those who had met and conversed with him once, were pleafed to meet and to converse with him again and again.

For some time he conversed only with the virtuous, the learned, and the wife; and the purity of his morals remained uncontaminated. But, alas! he fell, as others have fallen in fimilar circumstances. He suffered himfelf to be furrounded by a race of milerable beings, who were proud to tell that they had been in company with Burns, and had feen Burns as loofe and as foolish as themselves. He was not yet irrecoverably lost to temperance and moderation; but he was already almost too much captivated with their wanton rivals, to be ever more won back to a faithful attachment to their more fober charms. He now also began to contract fomething of new arrogance in conversation. Accustomed to be among his favourite affociates what is vulgarly but expressively called the cock of the company, he could scarcely retrain from indulging in fimilar freedom and dictatorial decifion of talk, even in the presence of

persons who could less patiently endure his presump-

tion. The subscription edition of his poems, in the mean time, appeared; and although not enlarged beyond that which came from the Kilmarnock piefs by any new pieces of emineut merit, did not fail to give entire fatistaction to the subscribers. He was now to close accounts with his bookfeller and his printer, to retire to the country with his profits in his pocket, and to fix upon a plan for his future life. He talked loudly of independence of spirit and fimplicity of manners, and boafted his resolution to return to the plough; yet still he lingered in Edinburgh, week after week, and month after month, perhaps expecting that one or other of his noble pations might procure him some permanent and competent annual income, which should fet him above all necessity of future exertions to earn for himself the means of subsistence; perhaps unconsciously reluctant to quit the pleasures of that voluptuous town-life to which he had for some time too willingly accustomed himself. An accidental diflocation or fracture of an arm or a leg confining him for fome weeks to his apartment, left him. during this time leifure for ferious reflection; and he determined to retire from the town without longer delay. None of all his patrons interposed to divert him from his purpose of returning to the plough, by the offer of any small pension, or any finecure place of moderate emolument, fuch as might have given him competence without withdrawing him from his poetical fludies. It feemed to be forgotten that a ploughman thus exalted into a man of letters was unfitted for his former toils, without being regularly qualified to enter the career of any new protession; and that it became incumbent upon those patrons who had called him from the plough, not merely to make him their companion in the hour of riot, not fimply to fill his purfe with gold for a few transient expences, but to secure him as far as was possible from being ever overwhelmed in distress in consequence of the favour which they had shown him, and of the habits of life into which they had feduced him. Perhaps indeed the fame delufion of fancy betrayed both Burns and his patrons into the mistaken idea, that, after all which had passed, it was still possible for him to return in cheerful content to the homely joys and simple toils of undissipated rural life,

In this temper of Burns's mind, in this state of his Burns. fortune, a farm and the excise were the objects upon which his choice ultimately fixed for future employment and fupport. By the furgeon who attended him during his illness, he was recommended with effect to the commissioners of excise; and Patrick Millar, Esq; of Dalfwinton, deceived, like Burns himfelf and Burns's other friends, into an idea that the poet and exciseman might yet be respectable and happy as a farmer, generously proposed to establish him in a sarm, upon conditions of lease which prudence and industry might easily render exceedingly advantageous. Burns eagerly accepted the offers of this benevolent patron. Two of the poet's friends from Ayrshire were invited to survey that farm in Dumfriesshire which Mr Millar offered. A leafe was granted to the poetical farmer at that annual rent which his own friends declared that the due cultivation of his farm might easily enable him to pay. What yet remained of the profits of his publication was laid out in the purchase of farm-stock; and Mr Millar might, for some short time, please himself with the persuasion that he had approved himself the liberal patron of genius; had acquired a good tenant upon his estate; and had placed a deferving man in the very fituation in which alone he himself defired to be placed, in order to be happy to his wishes.

Burns, with his Jane, whom he now married, took up their residence upon his farm. The neighbouring farmers and gentlemen, pleased to obtain for an inmate among them the poet by whose works they had been delighted, kindly fought his company, and invited him to their houses. He found an inexpressible charm in fitting down befide his wife, at his own firefide; in wandering over his own grounds; in once more putting his hand to the spade and the plough; in forming his inclosures, and managing his cattle. For fome months he felt almost all that felicity which fancy had taught him to expect in his new fituation. He had been for a time idle; but his muscles were not yet unbraced for rural toil. He now feemed to find a joy in being the husband of the mistress of his affections, in seeing himfelf the father of her children, fuch as might promife to attach him for ever to that modest, humble, and domestic life, in which alone he could hope to be permanently happy. Even his engagements in the fervice of the

excise did not, at the very first, threaten necessarily to

debase him by affociation with the mean, the gross, and

the profligate, to contaminate the poet, or to ruin the

But it could not be: it was not possible for Burns now to assume that soberness of fancy and passions, that fedateness of feeling, those habits of earnest attention to grofs and vulgar cares, without which fuccess in his new fituation was not to be expected. A thousand difficulties were to be encountered and overcome, much money was to be expended, much weary toil was to be exercifed, before his farm could be brought into a flate of cultivation, in which its produce might enrich the occupier This was not a prospect encouraging to a man who had never loved labour, and who was at this time certainly not at all disposed to enter into agriculture with the enthusiasm of a projector. The business of the excise too, as he began to be more and more employed in it, distracted his mind from the care of his farm, led him into gross and vulgar society, and exposed him to

as he had no longer sufficient fortitude to refist. Amidst the anxieties, diffractions, and feducements which thus arose to him, home became insensibly less and less pleafing; even the endearments of his Jane's affection began to lofe their hold on his heart; he became every day less and less unwilling to forget in riot those gathering forrows which he knew not to fubdue.

Mr Millar and some others of his friends would gladly have exerted an influence over his mind which might have preferved him in this fituation of his affairs, equally from despondency and from dissipation; but Burns's temper spurned all controul from his superiors in fortune. He refented, as an arrogant encroachment upon Millar wished to turn him from dissolute conviviality, to that steady attention to the business of his farm, without which it was impossible to thrive in it. His croffes and disappointments drove him every day more and more into diffipation; and his diffipation tended to enhance whatever was disagreeable and perplexing in the state of his affairs. He sunk, by degrees, into the boon companion of mere excisemen; and almost every drunken fellow, who was willing to spend his money lavishly in the alchouse, could easily command the company of Burns. The care of his farm was thus neglected; waste and losses wholly consumed his little capital; he refigned his leafe into the hands of his landlord; and retired, with his family, to the town of Dumfries, determining to depend entirely for the means of future

Support upon his income as an excise-officer.

Yet during this unfortunate period of his life, which passed between his departure from Edinburgh to settle in Dumfriesshire, and his leaving the country in order to take up his residence in the town of Dumfries, the energy and activity of his intellectual powers appeared to have been not at all impaired. In a collection of Scottifh fongs, which were published (the words with the music) by Mr Johnson, engraver in Edinburgh, in 4 vols 8vo, Burns, in many instances, accommodated new verses to the old tunes with admirable felicity and skill. He assisted in the temporary institution of a small subfcription library, for the use of a number of the welldisposed peasants in his neighbourhood. He readily aided, and by his knowledge of genuine Scottish phrafeology and manners greatly enlightened, the antiquarian refearches of the late ingenious Captain Grofe. He still carried on an epistolary correspondence, sometimes gay, fportive, humorous, but always enlivened by bright flathes of genius, with a number of his old friends, and on a very wide diversity of topics. At times, as it should feem from his writings of this period, he reflected, with inexpressible heart-bitterness, on the high hopes from which he had fallen; on the errors of moral conduct into which he had been hurried by the ardour of his foul, and in fome measure by the very generofity of his nature; on the difgrace and wretchedness into which he faw himself rapidly finking; on the forrow with which his misconduct oppressed the heart of his Jane; on the want and destitute misery in which it feemed probable that he must leave her and their infants; nor amidst these agonizing reslections did he fail to look, with an indignation half invidious, half contemptuous, on those who, with moral habits not more

Burns, many unavoidable temptations to drunken excess, fuch yet basked in the fun-shine of fortune, and were londed Burns, with the wealth and honours of the world, while his follies could not obtain pardon, nor his wants an honourable supply. His wit became from this time more gloomily farcastic; and his conversation and writings began to assume something of a tone of misanthropical malignity, by which they had not been before, in any eminent degree, diftinguished. But with all these failings, he was still that exalted mind which had raifed itself above the depression of its original condition: with all the energy of the lion, pawing to fet free his hinder limbs from the yet encumbering earth, he still appeared not less than archangel ruined!

His morals were not mended by his removal from his independence, that tenor of conduct by which Mr the country. In Dumfries his diffipation became still more deeply habitual; he was here more exposed than in the country to be folicited to share the riot of the diffolute and the idle: foolish young men flocked eagerly about him, and from time to time pressed him to drink with them, that they might enjoy his wicked wit. The Caledonian Club, too, and the Dumfriesshire and Galloway Hunt, had occasional meetings in Dumfries after Burns went to reside there, and the poet was of course invited to share their conviviality, and hesitated

not to accept the invitation.

In the intervals between his different fits of intemperance, he fuffered still the keenest anguish of remorfe, and horribly afflictive forefight. His Jane still behaved with a degree of maternal and conjugal tenderness and prudence, which made him feel more bitterly the evil of his misconduct, although they could not reclaim him. At last crippled, emaciated, having the very power of animation wasted by disease, quite broken-hearted by the fense of his errors, and of the hopeless miseries in which he faw himself and his family depressed; with his foul still tremblingly alive to the sense of shame, and to the love of virtue; yet even in the last feebleness, and amid the last agonies of expiring life, yielding readily to any temptation that offered the femblance of intemperate enjoyment, he died at Dumfries, in the fummer of 1796, while he was yet three or four years under the age of forty, furnishing a melancholy proof of the danger of fuddenly elevating even the greatest mind above its original level.

After his death it quickly appeared that his failings had not effaced from the minds of his more respectable acquaintance either the regard which had once been won by his focial qualities, or the reverence due to his intellectual talents. The circumstances of want in which he left his family were noticed by the gentlemen of Dumfries with earnest commiseration. His funeral was celebrated by the care of his friends with a decent folemnity, and with a numerous attendance of mourners, fufficiently honourable to his memory. Several copies of verfes were inferted in different newspapers upon the occasion of his death. A contribution, by subscription, was proposed, for the purpose of raising a small fund, for the decent support of his widow, and the education

of his infant children.

From the preceding detail of the particulars of this poet's life, the reader will naturally and juffly infer him to have been an honest, proud, warm-hearted man; of high passions and found understanding, and a vigorous and exemplive imagination. He was never known to excellent than his, with powers of intellect far inferior, descend to any act of deliberate meanness. In DumBur n- fries hearetained many respectable friends even to the consumed the lamp was again filled till the desired quan- Butter. r, last; and it may be doubted whether any poet of the present age has exercised a greater power over the minds of his readers. Burns has not failed to command one remarkable fort of homage, fuch as is never paid but to great original genius; a crowd of poetasters started up to imitate him, by writing verses as he had done in the Scottish dialect; but, O imitatores! servum pecus! To write rugged rhimes, in antiquated phrase, is not to imitate the poetry of Burns.

BURRAMPOOTER. See SANDPU, Encycl.

BUTTER is a substance so well known, that it is needless to give here any definition of it. It is one of the three component parts of milk, the other two being whey and cheefe. It is evident from the processes by which butter and cheese are made, that these two parts are not completely diffolved in the ferum or whey, but only diffused through it like an emulsion. They may indeed be separated from it by rest alone, without any

artificial preparation.

Butter, though used at present as food in most countries of Europe, was not known, or known very imperfectly, to the ancients. This, we think, is completely proved by Professor Beckmann in the second vo. lume of his History of Inventions. In our translation of the Hebrew Scripture, there is indeed frequent mention made of butter at very early periods; but, as the Professor well observes, the greatest masters of biblical criticism unanimously agree, that the word so translated fignifies milk or cream, or four thick milk, and cannot possibly mean what we call butter. The word plainly alludes to fomething liquid, which was used for washin, the feet, which was drunk, and which had fometimes the power of intoxicating; and we know that mare's milk may be so prepared as to produce the same effect. See Koumiss, Encycl.

The oldest mention of butter, the Professor thinks, is in the account of the Scythians given by Herodotus (lib. iv. 2.), who fays, that "these people pour the milk of their mares into wooden vessels, cause it to be violent. ly stirred or shaken by their blind slaves, and separate the part which arises to the surface, as they consider it as more valuable and delicions than what is collected below it." That this fubstance must have been a fost kind of butter, is well known; and Hippocrates gives a fimilar account of Scythian butter, and calls it mixigior, which Galen translates by the word Boulugov. The poet Anaxandrides, who lived foon after Hippocrates, deicribing the marriage feast of Iphicrates, who married the daughter of Cotys king of Thrace, fays, that the Thracians ate butter, which the Greeks at that time

confidered as a wonderful kind of food.

Dioscorides says, that good butter was prepared from the fattest milk, such as that of sheep or goats, by shaking it in a vessel till the fat was separated. To this butter he ascribes the same effects, when used externally, as those produced by our butter at present. He adds also, and he is the first writer who makes the observation, that fresh butter might be melted and poured over pulie and vegetables instead of oil, and that it might be employed in pastry in the room of other tat substances. A kind of foot likewife was at that time prepared from butter for external applications, which was used in curing inflammation of the eyes and other diforders. For this purpose the butter was put into a lamp, and when

tity of foot was collected in a veilel placed over it.

Galen, who dillinguishes and confirms in a more accurate manner the healing virtues of butter, expressly remarks, that cow's milk produces the fattest butter; that butter made from sheep's or goat's milk is less rich; and that ass's milk yields the poorest. He expresses his astonishment, therefore, that Dioscorides should fay that butter was made from the milk of sheep and goats. He assures us that he had seen it made from cow's-milk, and that he believes it had thence acquired its name. "Butter (fays he) may be very properly employed for ointments; and when leather is besmeared with it, the same purpose is answered as when it is rubbed over with oil. In cold countries, which do not produce oil, butter is used in the baths; and that it is a real fat, may be readily perceived by its catching fire when poured over burning coals." What has been here faid is sufficient to shew that butter must have been very little known to or used by the Greeks and the Romans in the time of Galen, that is, at the end of the fecond century.

The Professor having collected, in chronological order, every thing which he could find in the works of the ancients respecting butter, concludes, that it is not a Grecian, and much less a Roman, invention, but that the Greeks were made acquainted with it by the Scythians, the Thracians, and the Phrygians, and the Romans by the people of Germany. He is likewise decidedly of opinion, that when thefe two polished nations had learned the art of making it, they used it not as food, but only as an ointment, or fometimes as a medicine. "We never find it (fays he) mentioned by Galen and others as a food, though they have spoken of it as applicable to other purpofes. No notice is taken of it by Apicius; nor is there any thing faid of it in that respect by the authors who treat on agriculture, though they have given us very particular information concern-

ing milk, cheefe, and oil."

The case, however, is now very different. It is, in this country at least, so general an article of food, that the proper methods of making and curing it have engaged the attention of some of our ablest writers on agriculture. In addition to what has been faid on these Subjects under the titles Butter and DAIRY (Encyclopadia), our readers will probably be pleased with the following method of curing it, which is practifed by some farmers in the parish of Udney, in the county of Aberdeen, and gives to their butter a great superiority above that of their neighbours.

Take two parts of the best common salt, one part of fugar, and one part of faltpetre; beat them up together, and blend the whole completely. Take one ounce of this composition for every fixteen ounces of butter, work it well into the mals, and close it up for use.

Dr James Anderson, from whose View of the Agriculture of the County of Aberdeen this receipt is taken, fays, that he knows of no fimple improvement in economics greater than this is, when compared with the ulual mode of curing butter by means of common falt alone. "I have seen (continues he) the experiment fairly made, of one part of the butter made at one time being thus cured, and the other part cured with falt. alone: the difference was inconceivable. I should suppote that, in any open marker, the one would fell for

Butter. 30 per cent. more than the other. The butter eured with the mixture appears of a rich marrowy confiftence and fine colour, and never acquires a brittle hardness nor tastes falt; the other is comparatively hard and brittle, approaching more nearly to the appearance of tallow, and is much falter to the taste. I have ate butter eured with the above composition that had been kept three years, and it was as fweet as at first; but it must be noted, that butter thus cured requires to stand three weeks or a month before it is begun to be used. If it be fooner opened, the falts are not fufficiently blended with it; and fometimes the coolness of the nitre will then be perceived, which totally disappears afterwards."

The following observations respecting the proper method of keeping both milk and butter are by the same author, and we trust may prove useful. Speaking still of the county of Aberdeen, he says, "The pernicious practice of keeping milk in leaden veffels, and falting Butter butter in stone jars, begins to gain ground among some, of the fine ladies in this county, as well as elsewhere, from an idea of cleanliness. The fact is, it is just the reverse of cleanliness; for in the hands of a eareful perfon nothing can be more cleanly than wooden diffies, but under the management of a flattern they discover the feeret which stone dishes indeed do not.

"In return, these latter communicate to the butter and the milk, which has been kept in them, a poifouous quality, which inevitably proves destructive to the human constitution. To the prevalence of this practice I have no doubt we must attribute the frequency of palfies, which begin to prevail fo much in this kingdom; for the well known effect of the poison of lead is bodily debility, palfy-death!"

BYSAK, the first month of the Bengal year, begin-

ning in April.

AFFRES, the inhabitants of Caffrania, are generally confounded with the Hottentots; but, according to M. Vaillant, there is a confiderable difference between the manners, euftoms, and even appearance of these two nations.

The Caffres, fays he, are generally taller than the Hottentots, more robust, more fierce, and much bolder. Their figure is likewise more agreeable, and their countenances have not that narrowness at the bottom, nor their cheeks those prominences, which are so disagreeable among the Hottentots. A round figure, a nose not too flat, a broad forehead, and large eyes, give them an open and lively air; and if prejudice can overlook the colour of the skin, there are some Caffre women who, even in Europe, would be accounted pretty. These people do not make their faces ridiculous, by pulling out their eye-brows like the Hottentots; they tattoo themselves much, and particularly their bodies; their hair, which is frizzled very much, is never greafed, but their bodies are liberally anointed, merely with a view to preferve their vigour and agility.

The men generally bestow more attention on their dress than the women, and are remarkably fond of beads and copper rings. The women wear hardly any of the ornaments in which the other favages in Africa take fuch delight. They do not even wear copper bracelets; but their small aprons, which are still shorter than those of the Hottentots, are bordered with a few rows of glass-beads; and in this all their luxury confists. It would appear that the Caffres are not fo chafte as the Hottentots, because the men do not use a jackal to vail what nature teaches other men, even favages, to eonceal. A fmall cowl, which covers only the glans, inftead of dilplaying modesty, seems to announce the greatest indecency. This small eovering adheres to a

thong, which is fastened round their girdles, merely Castres that it may not be loft; for a Caffre, if he be not afraid of being hurt or flung by infects, eares very little whether his eowl be in its place or not. Our author faw one Caffre, who, instead of a cowl, wore a case made of wood, and ornamented with feulpture. This was a new and ridiculous fashion, which he had borrowed from a nation of black people who lived at a great distance from Caffraria.

In the hot feafon the Caffres go always naked, and retain nothing but their ornaments. In cold weather they wear kroffes made of ealves or oxens hides, which reach down to the ground; but whatever the weather be, both fexes go bare-headed, except that they fometimes, though rarely, fix a plume of feathers in their

The Caffre huts are more spacious and higher than those of the Hottentots, and have also a more regular form. The frames of them are constructed of wooden work, well put together, and very folid, being intended to last for a long time: for the Caffres, applying to agriculture, which the free Hottentots do not, remain fixed to one spot, unless something unexpected interrupt their repose.

A more perceptible industry, an aequaintance with fome of the most necessary arts of life, a little knowledge of agriculture, and a few religious dogmas, feen to announce that the Caffres approach much nearer to civilization than the Hottentots. They entertain a tolerably exalted idea of the Supreme Being and his power; they believe that the good will be rewarded, and the wieked punished, in a future state; but they have no notion of ereation, which indeed was not admitted by the fages of Greece and Rome. They praetise circumcision, but can give no account of its origin

Coffes, among them, or of the purpole for which the practice is

Polygamy is used among the Caffres; and on the death of a father the male children and their mothers share the succession among them. The girls remain with their mothers without property of any kind until they can procure husbands. One very fingular custom of the Caffres is, that they do not, in general, inter their dead, but transport them from the kraal to an open ditch, which is common to the whole horde. At this ditch favage animals feed at their leifure on the multitude of carcafes which are heaped together. Funeral honours are due only to kings and the chiefs of each horde, whose bodies are covered with a heap of stones collected into the form of a dome.

This nation is governed by a general, chief, or king, whose power is very limited. He appoints, however, the subordinate chiefs over the different hordes, and through them communicates his directions or orders. The arms of the Caffre are a club, two feet and a half in length, and where thickest three inches in diameter, and a plain lance or affagey. He despiles poisoned arrows, which are fo much used by some of the neighbouring nations; and with his two fimple weapons feeks always to meet his enemy face to face in the field. The Hottentot, on the contrary, concealed under a rock or behind a bush, deals out destruction, without being expofed to danger. The one is a perfidious tyger, which rushes treacherously on his prey; the other is a gene rous lion, which, having given warning of his approach, makes his attack boldly, and perishes if he prevail not against his antagonist.

CALCULUS, in mathematics, denotes a certain way of performing investigations and resolutions, which occur on many occasions, particularly in mechanical philosophy. Thus we fay, the antecedental calculus, the algebraical calculus, the arithmetical calculus, the differential calculus, the exponential calculus, the fluxional calculus, and the integral calculus. Of by much the greater part of these calculi some account has been given in the Encyclopædia Britannica; but there is one of them, of which no notice has been taken in that work.

The Antecedental CALCULUS, a geometrical method of reasoning, without any confideration of motion or velocity, applicable to every purpose to which the much celebrated doctrine of fluxions of the illustrious Newton has been, or can he, applied. This method was invented by James Glenie, Esq; " in which (he fays) every expression is truly and strictly geometrical, is founded on principles frequently made use of by the ancient geometers, principles admitted into the very first elements of geometry, and repeatedly used by Euclid himself. As it is a branch of general geometrical proportion, or univerfal comparison, and is derived from an examination of the antecedents of ratios, having given confequents and a given standard of comparison in the various degrees of augmentation and diminution they undergo by composition and decomposition, I have called it the antecedental calculus. As it is purely geometrical, and perfectly scientific, I have, since it first occurred to me in 1779, always made use of it instead of the sluxionary and differential calculi, which are merely arithmetical. Its principles are totally unconnected with the ideas of motion and time, which, SUPPL. VOL. I. Part I.

ftrictly speaking, are foreign to pure geometry and ab. Calculus. fract science, though, in mixed mathematics and natural philosophy, they are equally applicable to every investigation, involving the confideration of either with the two numerical methods just mentioned. And as many fuch investigations require compositions and decompositions of ratios, extending greatly beyond the triplicate and fubtriplicate, this calculus in all of them furnishes every expression in a strictly geometrical form. The flandards of comparison in it may be any magnitudes whatever, and are of course indefinite and innumerable; and the consequents of the ratios, compounded or decompounded, may be either equal or unequal, homogeneous or heterogeneous. In the fluxionary and differential methods, on the other hand, I, or unit, is not only the flandard of comparison, but also the consequent of every ratio compounded or decompounded."

This method is deduced immediately from Mr Glenie's Treatise on the Doctrine of Universal Comparison or General Proportion: And as the limits of the prefent work will not allow us to enter upon this subject, we therefore refer our readers to the two above mentioned treatifes, and to the fourth volume of the Trans-

actions of the Royal Society of Edinburgh.

We confess, however, that we do not expect such great advantage from the employment of this calculus as the very acute and ingenious author feems to promife from it. The mathematical world is truly indebted to him for the clear and discriminating view that he has taken of the doctrine of universal comparison, and we believe it to be perfectly accurate, and in some respects new. Notwithstanding the continual occupation of mathematicians with ratios and analogies, their particular objects commonly restricted their manner of conceiving ratio to some prefent modification of it. Hence it feems to have happened that their conceptions of it as a magnitude have not been uniform. But Mr Glenie, by avoiding every peculiarity, has at once attributed to it all the measurable affections of magnitude, addition or fubtraction, multiplication or division, and ratio or proportion. He is perhaps the first who has roundly considered ratio or proportion as an affection of ratio; and it is chiefly by the employment of this undoubted affection of ratio that he has rendered the geometrical analysis so comprehensive.

But when we view this antecedental calculus, not as a method of expressing mathematical science, but as an art, as a calculus in short, and consider the means which it must employ, and the notation which must be used. we become less sanguine in our hopes of advantage from The notation cannot (we think) be more simple than that of the fluxionary method, juftly called arithmetical; and if we infift on carrying clear conceptions along with us, we imagine that the arithmetical exposition of our fymbols will generally be the simpler of the two. The fcience of the antecedental calculus feems to consist in the attainable perception of all the simple ratios, whether of magnitudes, or ratios, or both, which concur to the formation of a compound and complicated ratio. Now this is equally, and more easily, attainable in the fluxionary or other arithmetical method, when the confequent is a simple magnitude. When it is not, the same process is farther necessary in both me-

thods, for getting rid of its complication.

We apprehend that it is a mistake that the geome-

the notions of time and motion. These notions were of ground rising gently to the east, and contained beintroduced by the illustrious inventor for the demonstration, but never occupy the thoughts in the use of his propositions. These are geometrical truths, no matter how demonstrated; and when duly considered, involve nothing that is omitted in the antecedental calculus. We even prefume to fay, that the complication of thought, in the contemplation of the ratios of ratios, is greater than what will generally arise from the additional elements, time and motion.

We do not find that any of our most active mathematicians have availed themselves of the advantages of this calculus, nor do we know any specimen that hasbeen exhibited of its eminent advantages in mathematical discussions. Should it prove more fertile in geometrical expressions of highly compounded or complicated quantities or relations, we should think it a mighty acquisition; being fully convinced that these afford to the memory or imagination an object (we may call it a fenfible picture) which it can contemplate and remember with incomparably greater clearness and steadiness than any algebraical formula. We need only appeal to the geometrical expressions of many fluents, which are to be seen in Newton's lunar theory, in the physical tracts of Dr Matthew Stewart, and others who have shewn a partiality for this method.

It would be very prefumptuous, however, for us to fay, that the accurate geometer and metaphyfician may not derive great advantages from profecuting the very ingenious and recondite speculations of Mr Glenie, in his doctrine of universal comparison.

CALENDAR, in chronology. See (Encycl.) Ka-LENDAR; and REVOLUTION, nº 184.

CALIPPIC PERIOD, in chronology, a period of 76 years, continually recurring; at every repetition of which, it was supposed by its inventor Calippus, an Athenian astronomer, that the mean new and full moons would always return to the fame day and hour.

About a century before, the golden number, or cycle of 19 years, had been invented by Meton; which Calippus finding to contain 19 of Nabonassar's year, 4 days, and 33 to avoid fractions he quadrupled it, and fo produced his period of 76 years, or 4 times 19; after which he supposed all the lunations, &cc. would regularly return to the fame hour. But neither is this exact, as it brings them too late by a whole day in 225

CALLAO, as it is called by its inhabitants, but more generally known to Europeans under the name of CAMPELLO, is a fmall island, which was visited by some of Lord Macartney's fuite on their voyage to China. In consequence of that visit, we have the following description of it in Sir George Staunton's Account of

" It lies opposite to, and about eight miles to the eastward of, the mouth of a considerable river on the coast of Cochin china, on the banks of which is situated the town of Fai foo, a place of some note, not far from the harbour of Turon. The bearing of the highest peak of Callao from this harbour is about fouth-east, distance thirty miles I'he extreme points of the island lie in latitude 1,° 53', and 15 57' north; the greatest length is from north-west to south-east, and is somewhat

Calendar trical method is more abstracted than the fluxionary, about five miles, and the mean breadth two miles. The Calland because the latter superadds to the notion of extension only inhabited part is on the south-west coast, on a slip tween the bottom of a semilunar bay and the mountains on each fide of it. Those mountains, at a distance, appear as if they formed two distinct islands. The fouthern mountain is the highest, and is about 1500 feet. The lower grounds contain about 200 acres. This fmall but enchanting fpot is beautifully diverlified with neat houses, temples, clumps of trees, imall hillocks fwelling from the plain, and richly decorated with firubbery and trees of various kinds; among which the elegant areca, rifing like a Corinthian column, is eminently confpicuous. A rill of clear water, oozing from the mountains, is contrived to be carried along the upper ridges of the vale, from whence it is occasionally conveyed through sluices, for the purpose of watering the rice-grounds, and appeared, though then in the dry feafon, fully fufficient for every purpose for which it could be wanted.

"The houses, in general, were clean and decent; a few were built with stone, and covered with tiles. One, probably the mansion of the chief person of the island, was inclosed by a stone wall, and the approach to it was through a gateway between two stone pillars. The house was divided into a number of apartments, of which the arrangement did not feem to want either tafte or convenience. This building flood at the head of the principal village, which confilted of about thirty habitations built of wood, chiefly the bamboo. Behind the village, and on the fide of the hill, was a cave, acceffible only by one way, through an irregular range of rocks. Within the cave, but near its mouth, was a fmall temple, commanding a view of the whole vale. Several other temples were dispersed over the plain, all of which were open in front, with a colonnade before them of round wooden pillars, painted red and varnished. The number of houses on the island scarcely exceeded fixty. Behind every house, not immediately in the principal village, were inclosures of fugar-canes, tobacco, and other vegetables, growing in great luxuriance. The mountains were covered with verdure, and feemed well calculated for rearing goats, of which the island produced a few.

"Beside the principal bay, there were several sandy inlets, with fmall patches of level ground behind them. Boats might easily land in any of these inlets; but a communication between them by land appeared to be exceedingly difficult, if not entirely prevented, by the fteep and rugged ridges which separated them from each other. On this account very flight works, and an e-Itablishment of a few men only, would be requisite for the defence of the island, a great part of its coast being impregnably fortified by nature. The depth of water in the bay and road was sufficient for ships of any burden, and there was perfect shelter from every wind except the fouth-west, to which quarter it was directly open. The short distance, however, from the continent in that direction would always prevent the fea from rifing high, though it might not be fufficiently near to break the force of the wind."

The inhabitants of this island are so exceedingly shy and afraid of strangers, that upon the approach of the English vessel, they all, except a very few, retired on board their galleys. When the British landed, therefore,

they found the doors of all the houses open, with feveral In the Encyclopædia Britannica its invention is given Cameleon domestic animals feeding before them, but neither man. woman, nor child within. After fome time, however, a person was perceived lurking among the neighbouring trees, who, finding he was observed, came forward with reluctance and evident marks of fear. While he was yet at some distance, he fell upon his knees, and touched the ground with his forehead feveral times. On approaching to him, it was noticed that the first joint of every one of his fingers and toes was wanting, and as if twisted off by violence; it was possible that he might have thus been treated by way of punishment for fome crime, and that he was confidered as the fittest person to be exposed to the supposed danger of watching the movements of the strangers coming ashore. In a little time fome others, hidden in the thickets, finding that no mischief was suffered by the first, ventured out. None of them could understand the Chinese interpreter; and not being able to read or write, there was no converfing with them by the medium of the Chinese characters. Recourfe was had to hieroglyphics, and rude figures were drawn of the articles which were proposed to be purchased; and this method succeeded tolerably well; poultry and fruits were brought for fale, for which high prices were given, purposely to conciliate the good will of those islanders. The few that were found grew foon familiar; and one old man preffingly invited the strangers to his house, situated upon an eminence, at a little distance. On arriving there, he introduced them to his wife, an old woman, who, after recovering from her aftonishment at the fight of figures fo different from those she had ever been accustomed to behold, laid, in a neat manner, before them fome fruits, fugar, cakes, and water. On departing from the house, this decent and hospitable couple made figns to testify their defire of seeing them again."

The possession of this island would be of such importance to any European nation who wished to trade fecurely with Tung Quin and Cochin-china, that it is faid the French had formerly fome thoughts of purchafing it. Sir George Staunton, however, is of opinion, that the want of shelter in the south-west monsoon would render it of little value, without a further fettlement near it upon the main land of Cochin-china; and he thinks, that if a folid establishment there could be productive of advantage to any European nation, it would necessarily be so to Great Britain; because, beside the opening which it would make for the fale of British manufactures among the people of the country, the British possessions in Hindostan would be sure of a very

considerable demand for their productions. CAMEL, in navigation, is a machine which has been described with sufficient accuracy in the Encyclopædia; but the following account of its invention, given by Professor Beckmann, is perhaps not unworthy of a

place in this Supplement.

"In the Zuyder-Zee, opposite to the month of the river Y, about fix miles from the city of Amsterdam, there are two fand banks, between which is a passage called the Pampus, which is sufficiently deep for small ships, but not for such as are large or heavy laden. In 1672 the Dutch contrived, however, to carry their numerous fleet through this passage, by means of large empty chefts fastened to the bottom of each ship; and this contrivance gave rife to the invention of the camel."

to the famous De Wit; in the German Cyclopædia to Campbell. Meyer a Dutch engineer of very confiderable eminence; but the Dutch writers, almost unanimously, ascribe the invention of the camel to a citizen of Amsterdam, who calls himself Meeuves Meindertsoon Bakker. " Some make the year of the invention to have been 1688, and others 1690. Much has been faid of the utility of this invention; but however beneficial it may be, we have reason to suppose that such heavy vessels as ships of war cannot be raifed up, in fo violent a manner, without fuftaining injury. A fure proof of this is the well known circumstance mentioned by Muschenbrock (Introduction ad Philosoph. Natur.), that the ports of a ship which had been raifed by the camel could not afterwards be

CAMELEON, one of the confellations of the fouthern hemisphere, near the fouth pole, and invisible in our latitude. There are 10 stars marked in this con-

stellation in Sharp's catalogue.

CAMELOPARDALUS, a new conficllation of the northern hemisphere, formed by Hevelius, consisting of 32 stars, first observed by him. It is situated between Cepheus, Cassiopeia, Perseus, the Two Bears, and Draco; and it contains 58 stars in the British ca-

CAMELLIA, in botany (fee Encycl.), is a plant which the Chinese call Cha-wha, or flower of tea, on account of the refemblance of the one to the other, and because its petals are sometimes mixed among the teas to increase their fragrance. Sir George Staunton, who calls it Gamellia Sefanqua, faw it flourishing on the fides and very high tops of mountains, where the foil confifted of little more than fragments of stone, crumbled into a fort of coarse earth by the joint action of the sun and rain. It yields, he fays, a not, from which is expressed an esculent oil, equal to the best which comes from Florence. On this account, it is cultivated in vast abundance; and is particularly valuable from the facility of its culture in fituations fit for little else.

CAMPBELL (George, D. D.), fo justly admired for his metaphyfical acuteness and various erudition, was, in 1719, born at Aberdeen, where his father, the reverend Colin Campbell, was one of the ministers of the established church. He was educated in his native city; and, after passing through the usual course of accademical learning, he studied divinity under the Rev. J. Chalmers, professor of divinity in Marischal College. -He was, in 1749, an unfuccessful candidate for the church of Fordown, though his competitor Mr Forbes was a man of very flender abilities, and supposed to be attached to the constitution and liturgy of the church of England. It might indeed be that attachment which contributed principally to procure him the living in preference to Mr Campbell.

The living of Fordown is in the gift of the crown; and it has generally been a rule with his majefly's ministers, to give such livings, when they become vacant, to those candidates who are favoured by the majority of land-owners in the parish. At the era of 1749, the land-owners in some of the northern and middle counties of Scotland were more generally attached to the constitution of the church of England than to that of their own establishment; and such was certainly the case in the parish of Ferdown.

T 2

he failed by a very fmall number, and was not long without an establishment. In 1750, he was presented, by Sir Thomas Burnett of Leys, to the living of Banchary Ternan, on the Dee, about twenty miles west from Aberdeen. From this he was translated, or, as the Scotch ecclefiastical phrase is, transported to Aberdeen in 1756, and nominated one of the city ministers, in the room of Mr John Biffet deceafed, a puritan of the old school, whose strictness and peculiarities are yet remembered by many in that place.

In 1759, on the decease of principal Pollock, he was chosen principal of the Marischal college, and succeeded to the divinity chair in 1771, on Dr Alexander Gerard being translated to the professorship of divinity in King's-college. Before his fettling in Aberdeen, he married Miss Grace Farquharson, daughter of Mr Farquharfon of Whitehouse, by whom he had no iffue. This amiable woman died about a year before him. They were an eminent pattern of conjugal affection.

From this time he enjoyed a remarkable share of good health and spirits. He had, all his life, a rooted aversion to medicine. He got the better of every ailment by a total and rigorous abstinence from all kind of fultenance whatever; and it was not till he was attacked by an alarming illness, about two years before his death, that he was perfuaded by his friends to call in medical aid. What nature could do, she had all along performed well; but her day was over, and fomething of art became necessary. Then, for the first time, he owned the utility of medical men, and declared his recantation of the very mean opinion he had formerly entertained of them and their art. A few months before his death, he refigned his offices of principal, professor of divinity, and one of the city ministers, and was in all succeeded by Dr W. L. Brown, late of Utrecht, a man of diftinguished abilities. Dr Campbell retained all his faculties entire to the last, and died on the 6th of April 1796 in the 77th year of his age. His character has been so justly drawn by his successor, that we shall give it to our readers in his words, adding only a circumstance or two, which we have reason to think will contribute to endear his memory to every liberal and en-

"Dr Campbell, as a public teacher, was long admired for the clearness and copiousness with which he illustrated the great doctrines and precepts of religion. and the strength and energy with which he enforced them. Intimately perfuaded of the truth and infinite consequence of what revelation teaches, he was strongly desirous of carrying the same conviction to the minds of his hearers, and delivered his discourses with that zeal which flows from ftrong impressions, and that power of perfuafion which is the refult of fincerity of heart, combined with clearness of understanding. He was fatisfied, that the more the pure dictates of the gospel were studied, the more they would approve themselves to the mind, and bring forth, in the affections and conduct, all the peaceable fruits of righteoufness. The unadulterated dictates of Christianity, he was, therefore, only studious to recommend and inculcate, and knew perfectly to discriminate them from the inventions and traditions of men. His chief study ever was, to direct belief to the great objects of practice: and, without these, he viewed the most orthodox pro-

But whatever was the cause of Mr Campbell's failure, fession as "a sounding brass, and a tinkling cymbal." Campbell But, besides the character of a preacher of righteous. nels, he had also that of a teacher of the science of divinity to fustain. How admirably he discharged this duty, and with what effect he conveyed the foundett and most profitable instruction to the minds of his scholars, let those declare who are now in various congregations of this country, communicating to their fellow Christians the fruits of their studies under so able and judicious a teacher. Discarding all attachment to human fystems, merely confidered as such, he tied his faith to the Word of God alone, possessed the happiest talent in investigating its meaning, and communicated to his hearers the result of his own inquiries, with a precision and perspicuity which brought light out of obfcurity, and rendered clear and fimple what appeared intricate and perplexed. He exposed, without reserve, the corruptions which ignorance, craft, and hypocrity, had introduced into religion, and applied his talent for ridicule to the best of all purposes, to hold up to contempt the absurdities with which the purest and fublimest truths had been loaded.

"Placed at the head of a public feminary of learning, he felt all the importance of fuch a fituation, and uniformly directed his influence to public utility. His enlarged and enlightened mind, justly appreciated the extensive consequence of the education of youth. He anticipated all the effects resulting to the great community of mankind, from numbers of young men iffuing, in regular fuccession, from the university over which he prefided, and occupying the different departments of focial life.

"His benevolent heart delighted to represent to itfelf the fludents under his direction usefully and honourably discharging the respective duties of their disferent professions; and some of them, perhaps, filling the most distinguished stations of civil fociety. With these prospects before him, he constantly directed his public conduct to their attainment. He never suffered his judgment to be warped by prejudice or partiality, or his heart to be seduced by passion or private interest. Those mean and ignoble motives by which many are actuated in the discharge of important trusts, approached not his mind. A certain honourable pride, if pride it may be called, diffused an uniform dignity over the whole of his behaviour. He felt the man degraded by the perversion of public character. His understanding alto clearly shewed him even personal advantage attached to fuch principles and practice, as he adopted from a fense of obligation, and those elevated conceptions of real worth which were fo congenial to his foul. He faw, he experienced, esteem, respect, and influence, following in the train of integrity and beneficence; but contempt, difgrace, aversion, and complete infignificance, closely linked to corruption and felfishness. Little minds are seduced and overpowered by selfish considerations, because they have not the capacity to look beyond the present advantage, and to extend to the misery that stands on the other fide of it. The same circumstance that betrays the perversity of their hearts, also evinces the weakness of their judgments.

" His reputation as a writer, is as extensive as the present intercourse of letters; not confined to his own country, but fpread through every civilized nation. In his literary pursuits, he aimed not, as is very often the shell cafe, with men of diffinguished literary abilities, merely at establishing his own celebrity, or increasing his fortune; but had chiefly at heart the defence of the great cause of Religion, or the elucidation of her dictates.

"At an early period he entered the lifts as a champion for Christianity against one of its acutest opponents. He not only triumphantly refuted his arguments, but even conciliated his respect by the handsome and dexterous manner in which his defence was conducted. While he refuted the infidel, he spared the man, and exhibited the uncommon spectacle of a polemical writer poffessing all the moderation of a Christian. But while he defended Christianity against its enemies, he was defirous of contributing his endeavours to increase, among its profesfors, the knowledge of the facred writings. Accordingly, in the latter part of his life, he favoured the world with a work, the fruit of copious erudition, of unwearied application, for almost thirty years, and of a clear and comprehensive judgment. We have only to regret, that the other writings of the New Testament have not been elucidated by the same pen that translated the Gospels. Nor were his literary merits confined to theology, and the studies more immediately connected with it. Philosophy, and the fine arts, are also indebted to his genius and labours; and in him the polite scholar was eminently joined to the

deep and liberal divine.

"Political principles will always be much affected by general character. This was also the case with Dr Campbell. In politics, he maintained that moderation which is the furest criterion of truth and rectitude, and was equally distant from those extremes into which men are so ant to run on great political questions. He cherished that patriotism which consists in wishing, and endeavouring to promote, the greatest happiness of his country, and is always subordinate to universal benevolence. Firmly attached to the British constitution, he was animated with that genuine love of liberty which it inspires and invigorates. He was equally averse to despotism and to popular anarchy; the two evils into which political parties are fo frequently hurried, to the destruction of all that is valuable in government. Party-spirit, of whatever description, he considered as having an unhappy tendency to pervert, to the most pernicious purposes, the best principles of the human mind, and to clothe the most iniquitous actions with the most specious appearances. Although tenacious of those sentiments, whether in religion or politics, which he was convinced to be rational and just, he never suffered mere difference of opinion to impair his good-will, to obstruct his good offices, or to cloud the chearfulness of conversation. His own conversation was enlivened by a vein of the most agreeable pleasantry."

So far was he from being influenced by jealoufy, or any portion of that corporation spirit which sometimes incites men of undoubted abilities to detract from the merit of every writer who fills not a station as conspicuous as their own, that he was loud in his praises of those, whom men of meaner minds would have looked upon with difgust, as upon prefumptuous rivals. This generofity was fully experienced by the writer of the article Miracle, in the Encyclopædia Britannica, who, though he had prefumed to treat the fubject differently from Dr Campbell, received from him such a testimony of approbation of what he had done, as he will hardly Campbell, look for from any other man in fimilar circumstances.

Among his other qualities, which fo much endeared him to all who had the honour of his acquaintance, Dr Campbell poffetfed an uncommon facility of paffing from the gravest to the most airy subjects, and from the livelieft to the gravest, without degrading the one or diminishing the pleasure of the other. The infirmities of age abated not the chearculness of his temper, nor did even the persuasion of approaching dissolution impair his ferenity.

We cannot conclude this fhort sketch better than with a list of his works, in the order in which they were published. In 1752, he published a Sermon,

preached before the Synod of Aberdeen.

1761. A Differtation on Miracles, against Mr Hume. This treatife is well known to the learned world. He obtained, and defervedly obtained, a very high reputation, not only from the able manner in which he handled the subject, but from the liberal style in which he addressed his antagonist. It was speedily translated into French, German, and Dutch.

1771. A Sermon before the Society for Propaga-

ting Christian Knowledge, Edinburgh.

before the Synod of Aberdeen.

1776. The Philosophy of Rhetoric, 2 vols 8vo. A work which discovers a clearness of discernment, and accuracy of observation, which justly intitled him to be ranked among the most judicious critics. He entered on this inquiry as early as 1750, when a part of the work was composed. The laws of elegant composition and criticism are laid down with great perspicuity: but the most valuable part of the work is undoubtedly the theory of evidence, to which we know nothing superior, perhaps nothing equal, on the subject, in our own or any other language. His philosophy, in general, is the philotophy of Dr Reid; and where he differs from that acute reasoner respecting alstraction, and some other objects of metaphyfical disquisition, we think it impossible to refuse him the pre-eminence in every thing but style.

1777. A Sernion on the King's Fast-day, on Allegiance, first printed in 4to, and afterwards, at the expence of government, fix thousand copies were printed in 12mo, enlarged with notes, and fent to America, when the unhappy struggle had, however, put on appearances which prevented the effect hoped for from

this fermon.

1780. An Address to the People of Scotland on the Alarms which have been raifed by what is called the Popish Bill. This is a powerful dissuasive from bigotry, and every species of religious persecution.
1793. His Magnum Opus. The translation of the

Gospels, with Preliminary Differtations, 2 vols 4to.

CAMPHOR, or CAMPHIRE (see Encycl.), is, in China, obtained by boiling the branches, twigs, and leaves, of the Laurus-Camphora in water, upon the furface of which it is found swimming in the form of an oil, or adhering, in a glutinous form, to a wooden rod, with which the boiling matter is conftantly stirred. The glutinous mass is then mixed with clay and lime, and put into an earthen veffel, with another of the same fize properly luted over it; the lower veffel being placed over a flow fire, the camphor gradually fublimes through the clay and lime, and adheres to the fides of the upper

Camphor.

Canabac, veffel, forming a cake of a shape corresponding to the Canals. cavity which received it. It is, however, less pure and much weaker than what is discovered in a solid state among the fibres of the trunk, as turpentine is found in different forts of pines. In the great, but ill-peopled, island of Borneo, and also in Japan, the camphor tree is felled for the fole purpose of finding this costly drug in substance among the splinters of the trunk, in the same manner as other trees are selled in Louisiana mcrely for collecting the fruit they bear upon their fummits. The Borneo, or Japan camphoi, is pure, and fo very strong, as readily to communicate much of its odour and its virtues to other inspiffated oils, which thus pass for real camphor; and this adulterated drug is fold by Chinese artists at a vastly lower price than they gave themselves for the genuine substance from which last is placed once its own depth above the level Borneo or Japan.

Sir George Staunton, from whom we have this account, does not inform us whether the camphor-tree of China, if felled and torn into splinters, would not produce as large quantities of the drug, and equally pure, as the trees of Borneo and Japan; but he affures us, that in China it is never fo torn, being there a large and valuable timber-tree. "It is used (says hc) in the best buildings of every kind, as well as for masts of veffels, and bears too high a price to allow of any part, except the branches, being cut up for the fake of the

drug."

CANABAC, an island lying contiguous to BULAM on the western coast of Africa, and inhabited by a sierce people, governed by two kings or chiefs. It would appear that the Canabace had been very troublesome to their neighbours, fince the inhabitants of some other islands in that cluster rejoiced at the settlement of the English in Bulam, hoping to find in them a defence

against the usurpations of the Canabacs.

CANALS of COMMUNICATION may be of fuch advantage in a commercial or agricultural country, that every attempt to render them more convenient, and less expensive in the construction, is intitled to public notice. In the Encyclopædia, an account, fufficiently perspicuous, is given of the common canals with locks; but in many cases it is very difficult to provide a sufficient quantity of water for the confumption of a canal where many boats are to pass. Different attempts have therefore been made, by ingenious men, to fave water in the passing of boats or lighters from one lock of a canal to another; and, among thefe, perhaps none is more deferving of public favour than the following, by the late Mr James Playfair of Rudel-street, architect. We shall state his invention in his own words.

"The nature and principle of this manner of faving water confift in letting the water which has ferved to raife or fall a boat or barge from the lock, pass into refervoirs or cifterns, whose apertures of communication with the lock are upon different levels, and which may be placed or constructed at the side or sides of the lock with which they communicate, or in any other contiguous fituation that circumstances may render eligible; which apertures may be opened or faut at pleasure, so that the water may pass from the lock to each reservoir of the canal, or from each refervoir to the lock, in the following manner: The water which fills the lock, when a boat is to ascend or descend, instead of being paffed immediately into the lower part of the canal, is

let pass into these cisterns or reservoirs, apon different Canals levels; then, their communications with the lock being fhut, they remain full until another veffel is wanted to pass; then, again, the cisterns are emptied into the lock, which is thereby nearly filled, fo that only the remainder which is not filled is supplied from the higher part of the canal. Each of these cisterns must have a furface not less than that of the lock, and must contain half as much water as is meant to be expended for the passing of each vessel. The cistern the most elevated is placed twice its own depth (measuring by the aperture, or communicating opening of the cifterns) under the level of the water in the higher part of the canal. The fecond eiftern is placed once its own depth under the first, and so on are the others, to the lowest; of the water in the lower part of the canal. The apertures of the intermediate cifferns, whatever their number may be, must all be equally divided into different levels; the surface of the water in the one being always on the level of the bottom of the aperture of the ciftern which is immediately above. As an example of the manner and rule for constructing these cisterns, fuppose that a lock is to be constructed twelve feet deep, that is, that the veffel may afcend or descend twelve feet in passing. Suppose the lock fixty feet long and fix feet wide, the quantity of water required to fill the lock, and to pass a boat, is 4320 cubic feet; and suppose that, in calculating the quantity of water that can be procured for supplying the canal, after allowing for waste, it is found (according to the number of boats that may be expected to pass) that there will not be above 800 cubic feet for each; then it will be necesfary to fave five-fixths of the whole quantity that in the common case would be necessary: to do which ten cisterns must be made (the mode of placing which is expressed in the drawing, fig. 1. Plate VII.), each of which must be one foot deep, or deeper at pleasure, and each must have a surface of 360 feet square, equal to the furface of the lock. The bottom of the aperture of the lowest ciftern must be placed one foot above the level of the water in the lower part of the canal, or eleven feet under the level of the high water; the fecond ciftern must be two feet above the level of the low water; the third three feet, and so on of the others; the bottom of the tenth, or uppermost eistern, being ten feet above the low water, and two feet lower than the high water; and, as each eistern must be twelve inches in depth, the furface of the water in the higher ciftern will be one foot under the level of the water in the upper part of the canal. The citterns being thus constructed, when the lock is full, and the boat to be let down, the communications between the lock and the cifterns, which until then have all been shut, are to be opened in the following manner: first, the communication with the higher eitlern is opened, which, being at bottom two feet under the level of the water in the lock, is filled to the depth of one foot, the water in the lock descending one foot also at the same time; that communication is then flut, and the communication between the lock and the fecond ciftern is opened; one foot more of the water then passes into that eistern from the lock, and fills it; the opening is then shut: the fame is done with the third, fourth, fifth, fixth, feventh, eighth, ninth, and tenth, ciflerns, one by one, until they

eistern, is filled, there remains but too feet depth of water in the lock. The communication between the lock and the lower part of the canal is then opened, and the last two feet depth of water is emptied into the lower part of the canal. By this means, it is evident, that, instead of twelve feet depth of water being let descend into the lower part of the canal, there is only two feet. depth that descends, or one-fixth of the whole; therefore, instead of 4320 cubic feet being used, there are only 720 cubic feet used: the remainder of the water in the cifterns being used as follows. When another boat is to mount, the fluices being then flut, and the boat in the lock, the tenth or lowermost eitlern is emptied into the lock, which it fills one foot; the communication being then shut, the next lowest cistern, or the ninth, is emptied into the lock, which is thereby filled another foot; and fo, in like manner, all the other citterns are emptied one after another, until the higher cifern being emptied, which fills the tenth foot of water in the lock, there remains but two feet of water to fill, which is done from the upper part of the canal, by opening the higher fluice to pass the boat; by that means, the same quantity of water descends from the upper part of the canal into the lock, that in the other case descended from the lock into the lower part of the canal; fo that, in both cases, the same quantity of water is faved, that is, five-fixths of what would be necesfary were there no cifterns. Suppose again that, upon the fame canal, and immediately after the twelve feet lock, it would be advantageous to construct one of eighteen feet; then, in order not to use any greater quantity of water, it will be necessary to have fixteen eisterns, upon different levels, communicating with the lock in the same manner. Should, again, a lock of only fix feet be wanted, after that of eighteen, then it will only be necessary to have four cisterns on different levels, and fo of any other height of lock. The rule is this: for finding the number and fize of the cifterns, each cistern being the same in superficies with the lock, its depth must be such as to contain one half the quantity of water meant to be used in the passing of one boat. The depth of the lock, divided by the depth necessary for such a cistern, will give, in all cases, the whole number of cifterns, and two more: deduct the number two, therefore, from the number which you find by dividing the depth of the lock by the depth of one ciftern, and you have always the number of ciflerns required; which are to be placed upon different levels, according to the rule already given. The above is the principle and manner of using the lock, for faving water in canals, and for enabling engineers to construct locks of different depths upon the same canal, without using more water for the deep locks than for the shallow ones. With regard to the manner of difpoling the cifterns, the circumstances of the ground, the declivity, &c. will be the best guide for the en-

But supposing a sufficiency of water, or admitting that this method of Mr Playfair's of faving it, where defective, is adequate to his fondest experiations - still, in passing numerous locks, where the rife is confiderable, the interruption is fo great, that it has often been wished that an eligible method of lowering and elevatmg boats could be devifed, without the affiftance of

nals they are all filled; and, when the tenth, or lowermost water-locks. Though this is evidently at first view Canals, practicable, and feveral different modes of doing it have been fuggested, some of which have actually been carried into effect, yet all of them have been found to be attended with fuch inconvenience as to render an

improvement in this respect still necessary.

In China, where water-carriage is more generally practifed than in any kingdom of Europe, boats are raised and lowered from one canal into another by sliding them along an inclined plane: but the contrivances for effecting that purpose are so awkward, and such a number of hands are required, that it has in general been deemed inexpedient to refort to that mode of practice in Europe. Several devices, that discover considerable ingenuity, however, have been published, with a view to facilitate this operation; either by rendering the motion up the inclined plane more equable, or producing a power fufficient to move these great weights. But none of them have yet been so simple in their conftruction as could be wished, nor have they afforded fatisfaction in practice. For the greater part of them, likewife, patents have been granted; fo that whatever be their value, no engineer could avail himself of them without previously purchasing a licence from the pa-

The following contrivance for this purpole is the invention of James Anderson, LL. D. whose knowledge of economics is well known, and of whose public spirit there cannot be a doubt. Instead of applying for a patent, to fecure to himself the fruits of his ingenuity, he published, for the good of his countrymen in general, his device, in the View of the Agriculture of the County of Aberdeen, which he drew up for the confideration of the board of agriculture. He introduces it to public notice with justly observing, that it possesses at least the merit of simplicity, in as high a degree, perhaps, as could be wished; and, " in the opinion (fays he) of very good judges of matters of this fort, to whom the plan has been shewn, it has been deemed fully adequate to the purpose of raising and lowering boats of a moderate fize, that is, of 20 tons, or downwards; and it is the opinion of mon men with whom I have converfed, who are best acquainted with the inland navigations, that a boat of from 10 to 15 tons is better than those of a larger fize. When feveral are wanted to be fent at once, they may be affixed to one another, as many as the towing-horse can conveniently draw. Were boats of this fize adopted, and were all the boats on one canal to be of the same dimensions, it would prove a great convenience to a country in a flate of beginning improvements; because the expence of fuch a boat would be fo trifling, that every farmer could have one for himself, and might of course make use of it when he pleated by the aid of his own horse, without being obliged to have any dependence on the time that might suit the convenience of his neighbour; and if two or more boats were going from the same neighbourhood, one horse could serve the whole.

"You are to suppose that fig. 2. (Plate VII.) represents a bird's-eye view of this simple apparatus, asfeen from above. A is supposed to be the upper reach of the canal, and B the lower reach, with the apparatusbetween the two. This confifts of three divisions; the middle one, extending from C to D, is a folid piece of mafonry, raifed from a firm foundation below the level

ded into five parts, viz. ddd, where the wall rifes only to the height of the water in the upper reach, and ee, two pillars, raifed high enough to support the pivots of a wheel or pulley g, placed in the polition there

"The fecond division h confilts of a wooden coffer, of the same depth nearly as the water in the upper reach, and of a fize exactly fitted to contain one of the boats. This communicates directly with the upper reach, and being upon the fame plane with it, and fo connected with it as to be water-tight, it is evident, from inspection, that nothing can be more easy than to float a boat into this coffer from the upper reach; the part of the wheel that projects over it being at a fufficient height above it, so as to occasion no fort of

interruption.

"Third division. At i is represented another coffer, precifely of the same dimensions with the first. But here two fluices, which were open in the former, and only reprefented by dotted lines, are supposed to be flut, fo as to cut off all communication between the water in the canal and that in the coffer. As it was impossible to represent this part of the apparatus on so small a scale, for the sake of illustration it is represented more at large in fig. 5. where A, as before, reprefents the upper reach of the canal, and b one of the coffers. The fluice k goes into two cheeks of wood, joined to the masonry of the dam of the canal, so as to fit perfectly close; and the sluice f fits, equally close, into cheeks made in the fide of the coffer for that purpose; between these two sluices is a small space o. The coffer, and this division o, are to be supposed full of water, and it will be easy to see that these sluices may be let down, or drawn up at pleasure, with much

" Fig. 6. represents a perpendicular section of these parts in the same direction as in fig. 5. and in which

the same letters represent the same parts.

"Things being thus arranged, you are to suppose the coffer b to be suspended, by means of a chain passed over the pulley, and balanced by a weight that is fufficient to counterpoise it, suspended at the opposite end of the chain. Suppose, then, that the counterpoise be made somewhat lighter than the coffer with its contents, and that the line mn (fig. 6.) represents a divifion between the folid fides of the dam of feparation, which terminates the upper reach, and the wooden coffer, which had been closed only by the pressure of its own weight (being pushed a very little from A towards B, beyond its precise perpendicular swing), and that the joining all round is covered with lifts of cloth put upon it for that purpole; it is evident that, so long as the coffer is suspended to this height, the joining must be water-tight; but no fooner is it lowered down a little than this joining opens, the water in the small division o is allowed to run out, and an entire separation is made between the fixed dam and this moveable coffer, which may be lowered down at pleasure without losing any part of the water it contained.

"Suppose the coffer now perfectly detached, turn to fig. 3. which represents a perpendicular section of this apparatus, in the direction of the dotted line pp

Canals. of the bottom of the fecond reach: this is again divi- ed by its chain, and now perfectly detached from all Canal other objects, and balanced by a counterpoile i, which is another coffer exactly of the same size, as low down as the level of the lower reach. From infpection only it is evident, that, in proportion as the one of thefe weights rifes, the other must descend. For the prefent, then, suppose that the coffer h is by some means rendered more weighty than i, it is plain it will defcend while the other rifes; and they will thus continue till b comes down to the level of the lower reach, and i rifes to the level of the higher one.

" Fig. 4. represents a section in the direction AB (fig. 2.), in which the coffer i (feen in both fituations) is supposed to have been gradually raised from the level of the lower reach B, to that of the higher A, where it now remains flationary; while the coffer b (which is concealed behind the masonry) has descended in the mean time to the level of the lower reach, where it closes by means of the juncture rs, fig. 6. (which juncture is covered with lifts of cloth, as before explained at mn, and is of course become water-tight,) when, by lifting the fluice t, and the corresponding fluice at the end of the canal, a perfect communication by water is established between them. If, then, instead of water only, this coffer had contained a boat, floated into it from the upper reach, and then lowered down, it is very plain, that when these sluices were removed, after it had reached the level of the lower reach, that boat might have been floated out of the coffer with as much facility as it was let into it above. Here then we have a boat taken from the higher into the lower canal;

and, by reverfing this movement, it is very obvious

that it might be, with equal eafe, railed from the lower

into the higher one. It now only remains that I

should explain by what means the equilibrium between

these counter-balancing weights can be destroyed at pleafure, and the motion of course produced.

"It is very evident; that if the two corresponding coffers be precifely of the same dimensions, their weight will be exactly the same when they are both filled to the same depth of water. It is equally plain, that should a boat be stoated into either or both of them. whatever its dimensions or weight may be, so that it can be contained affoat in the coffer, the weight of the coffer and its contents will continue precifely the same as when it was filled with water only: hence, then, fupposing one boat is to be lowered, or one to be raised at a time, or supposing one to be raised and another: lowered at the fame time-they remain perfectly in equilibrium in either place, till it is your pleasure to destroy that equilibrium. Suppose, then, for the prefent, that both coffers are loaded with a boat in each, the double fluices both above and below closed; and suppose also that a stop-cock u, in the under edge of the fide of the lower coffer (fig. 4. and 6.), is opened, some of the water which served to float the boat in the coffer will flow out of it, and confequently that coffer will become lighter than the higher one; the upper coffer will of course descend, while the other mounts upwards. When a gentle motion has been thus communicated, it may be prevented from accelerating, merely by turning the stop-cock so as to prevent the loss of more water, and thus one coffer will continue to (fig. 2.). In fig. 3. h represents an end view of the ascend, and the other to descend, till they have assumed coffer, indicated by the same letter as in fig. 2. suspend their stations respectively; when, in consequence of a

" Precisely the same effect will be produced when the

coffers are filled entirely with water.

"It is unnecessary to add more to this explanation, except to observe, that the space for the coffer to defeend into must be deeper than the bottom of the lower canal, in order to allow a free descent for the coffer to the requisite depth; and of course it will be necessary to have a small conduit to allow the water to get out of it. Two or three inches free, below the bottom of the

canal, is all that would be necessary.

"Where the height is inconfiderable, there will be no occasion for providing any counterpoise for the chain, as that will give only a fmall addition to the weight of the undermost coffer, so as to make it preponderate, in circumstances where the two coffers would otherwise be in perfect equilibrium: but, where the height is confiderable, there will be a necessity for providing fuch a counterpoife; as, without it, the chain, by becoming more weighty every foot it descended, would tend to destroy the equilibrium too much, and accelerate the motion to an inconvenient degree. To guard against this inconvenience, let a chain of the same weight, per foot, be appended at the bottom of each coffer, of fuch a length as to reach within a few yards of the ground where the coffer is at its greatest height (fee fig. 3.); it will act with its whole weight upon the highest coffer while in this position; but, as that gradually descended, the chain would reach the ground, and, being there supported, its weight would be diminished in proportion to its descent; while the weight of the chain on the opposite fide would be augmented in the same proportion, so as to counterpoise each other exactly, in every fituation, until the uppermost chain was raised from the ground. After which it would increase its weight no more; and, of course, would then give the under coffer that preponderance which is neceffary for preferving the machine fleady. The under coffer, when it reached its lowest position, would touch the bottom on its edges, which would then support it, and keep every thing in the same position, till it was made lighter for the purpose of ascending.

"What constitutes one particular excellence of the apparatus here proposed is, that it is not only unlimited as to the extent of the rife or depression of which it is susceptible (for it would not require the expenditure of one drop more water to lower it one hundred feet than one foot); but it would also be easy so to augment the number of pulleys at any one place as to admit of two, three, four, or any greater number of boats being lowered or elevated at the same time; so that let the succession of boats on such a canal be nearly as rapid as that of carriages upon a highway, none of them need be delayed one moment to wait an opportunity of passing: a thing that is totally impracticable where water-locks are employed; for the intercourse, on every canal constructed with water-locks, is necessarily limited to a certain degree, beyond which it

is impossible to force it.

SUPPL. VOL. I. Part I.

" For example: suppose a hundred boats are following each other, in such a rapid succession as to be only half a minute behind each other: By the apparatus here proposed, they would all be elevated precisely as they came; in the other, let it be supposed that the lock is fo well constructed as that it takes no more than five minutes to close and open it; that is, ten minutes in the whole to each boat (for the lock, being once filled, must be again emptied before it can receive another in the same direction): at this rate, fix boats only could be paffed in an hour, and of course it would take fixteen hours and forty minutes to pass the whole hundred; and as the last boat would reach the lock in the space of fifty minutes after the first, it would be detained fifteen hours and fifty minutes before its turn would come to be raised. This is an immense detention: but if a succession of boats, at the same rate, were to follow continually, they never could pass at all. In short, in a canal confirmeted with water-locks, not more than fix boats, on an average, can be passed in an hour, so that beyond that extent all commerce must be stopped; but, of the plan here proposed, fixty, or fix hundred, might be passed in an hour if necessary, so as to occasion no fort of interruption whatever. These are advantages of a very important nature, and ought not to be overlooked in a commercial country.

"This apparatus might be employed for innumerable other uses as a moving power, which it would be foreign to our present purpose here to specify. Nor does its power admit of any limitation, but that of the strength of the chain, and of the coffers which are to support the weights. All the other parts admit of being made so immoveably firm as to be capable of sup-

porting almost any affignable weight.

"I will not enlarge on the benefits that may be derived from this very fimple apparatus: its cheapness, when compared with any other mode of raising and lowering vessels that has ever yet been practifed, is very obvious; the waste of water it would occasion is next to nothing; and when it is considered that a boat might be raised or lowered fifty feet nearly with the same ease as five, it is evident that the interruptions which arise from frequent locks would be avoided, and an immense saving be made in the original expence of the canal, and in the annual repairs.

"It is also evident, that an apparatus, on the same principle, might be easily applied for raising coals or metals from a great depth in mines, wherever a very small stream of water could be commanded, and where

the mine was level-free."

CANARY-BIRD, of which a description is given in the Encyclopædia, was not known in Europe till towards the end of the 15th century. Even in 1555 Bellon, who about that time described all the birds then known, does not so much as mention it. When it was first brought from the Canary Islands, it was so dear that it could be purchased only by people of fortune, who were often imposed upon. It was called the sugar-bird, because it was said to be fond of the singarcane, and could eat sugar in great abundance. This is

(A) "It does not feem necessary to adopt any other contrivance than the above for regulating the motions; but if it should be found necessary, it would be easy to put a ratch-wheel on the same axle.

Canal, Canary-Bird. Candle. geon, to which four drams of fugar was given, died in fourthours; and that a duck, which had swallowed five

drams, did not live seven hohrs.

In the middle of the last century canary-birds began to be bred in Europe; and to this the following circumitance, related by Olina, feems to have given occafion: " A veffel which, among other commodities, was carrying a number of canary birds to Leghorn, was wrecked on the coast of Italy; and these birds being thus fet at liberty, flew to the nearest land, which was the island of Elba, where they found the climate so favourable, that they multiplied, and perhaps would have become domesticated, had they not been caught in fnares; for it appears that the breed of them there has been long destroyed. Olina fays, that the breed foon degenerated; but it is probable, that by much the greater part of these canary-birds were males, which coupling with birds of the island, produced mules, fuch as are described by Gesner and other naturalists."

"Various treatises have been published in different languages on the manner of breeding these birds, and many people have made it a trade, by which they have acquired confiderable gain. It does no difcredit to the industry of the Tyrolians, that they have carried it to the greatest extent. At Ymst there is a company, who, after the breeding feafon is over, fend out persons to different parts of Germany and Switzerland to purchase birds from those who breed them. Each person brings with him commonly from three to four hundred, which are afterwards carried for fale, not only through every part of Germany, but also to England, Russia, and even Constantinople. About fixteen hundred are brought every year to England; where the dealers in them, notwithstanding the considerable expence they are at, and after carrying them about on their backs, perhaps a hundred miles, fell them for five shillings a piece. This trade, hitherto neglected, is now carried on in Schwarzwalde; and at prefent there is a citizen at Gottingen who takes with him every year to England several canary bird and bulfinches (loxia pyrrhula), with the produce of which he purchases such small wares as he has occasion for." - Professor Beckmann's History of Inventions and Discoveries.

CANARY-Seed. See PHALARIS, Encycl.-Professor Beckmann doubts whether the plant which bears the canary-feed be the phalaris of the ancients, because that name feems to have been given by Pliny to more than one species of grass. He thinks it very probable, however, that the plant which the modern botanists call phalaris was first brought from the Canary Islands to Spain, where it began to be cultivated, as well as in the fouth of France, as foon as canary-birds came into general esteem. At present it is cultivated in various places, and forms no inconfiderable branch of trade, particularly in the island of Sicily, where it is called Scagliuola or Scaghiola. Were it not that the grains are not easily freed from the husks, this plant might be cultiveted for the food of man, for its feeds yield a good kind of meal. The phalaris has by several writers been confounded with argol or the lichen rocolla of Linnæus; but they are very different plants. See LICHEN Rocolla in this Supplement.

Canary- rather a fingular circumstance, sugar being to many no particular description. Its use, however, is so great, Canalle, fowls a poison. Experiments have shewn, that a pi- that every information tending to its improvement must, we should think, be acceptable to our readers. Of the common method of making candles, whether of wax or of tallow, a fufficient account has been given in the Encyclopædia; but candles of every kind are far from being yet brought to that degree of perfection of which they feem susceptible. Thus, for example, the light of a candle, which is fo exceedingly brilliant when first fnuffed, is very speedily diminished to one-half, and is usually not more than one-fifth or one-fixth, before the uneafiness of the eye induces us to snuff it. Hence it follows, that if candles could be made fo as not to require fnuffing, the average quantity of light afforded by the fame quantity of combustible matter would be more than doubled. It may likewife be worthy of inquiry, fince the cost and duration of candles are easily ascertainable, whether more or less light is obtained at the same expence during a given time, by burning a number of small candles instead of one of greater thickness.

To determine this last point, a method must be found of measuring the comparative intensities of light, for which fee Photometer in this Supplement. With respect to the desideratum first mentioned, we have fome very ingenious observations and well-contrived experiments by Mr Nicholfon, in the fecond number of his valuable Journal, which we shall here insert nearly

in the words of their author.

In every process of combustion the free access of air is of the utmost consequence. When a candle has a very slender wick, the slame is small and of a brilliant white colour; if the wick be large, the combustion is less perfect, and the flame brown; and a wick still larger, not only exhibits a brown flame, but the lower internal part appears dark, and is occupied by a portion of volatilized matter, which does not become ignited till it has ascended towards the point. When the wick is either very large or very long, part of this matter escapes combustion, and shews itself in the form of coal or smoke. The same things take place in the burning of a lamp; but when the wick of a lamp is once adjusted as to its length, the slame continues nearly in the fame state for a much longer time than the slame of a

" Upon comparing a candle with a lamp (fays Mr Nicholfon), two very remarkable particulars are immediately feen. In the first place, the tallow itself, which remains in the unfused state, affords a cup or cavity to hold that portion of melted tallow which is ready to flow into the lighted part of the wick. In the second place, the combustion, instead of being confined, as in the lamp, to a certain determinate portion of the fibrous matter, is carried, by a flow fuccession, through the whole length. Hence arises the greater necessity for frequent fnuffing the candle; and hence also the station of the freezing point of the fat oil becomes of great confequence. For it has been shewn, that the brilliancy of the flame depends very much on the diameter of the wick being as small as possible; and this requifite will be most attainable in candles formed of a material that requires a higher degree of heat to fuse it. The wick of a tallow candle must be made thicker in proportion to the greater fusibility of the material, . which would otherwise melt the fides of the cup, and CANDLE, a thing fo univerfally known as to need run over in streams. The slame will therefore be yelandle low, imoky, and obscure, excepting for a short time the slame; in consequence of which, the tube and the Candle. immediately after fnuffing. Tallow melts at the old degree of Fahrenheit's thermometer; spermaceti at the 133d degree; the fatty matter formed of flesh, after long immersion in water, melts at 127 degrees; the pela of the Chinese at 145 degrees; bees-wax at 142 degrees; and bleached wax at 155 degrees. Two of these materials are well known in the fabrication of cancles. Wax in particular does not afford fo brilliant a flame as tallow; but, on account of its less fusibility, the wick can be made smaller, which not only affords the advantage of a clear perfect flame, but from its flexibility it is disposed to turn on one side, and come in contact with the external air, which completely burns the extremity of the wick to white ashes, and thus performs the office of fnuffing. We see therefore that the important object to fociety of rendering tallow candles equal to those of wax, does not at all depend on the combustibility of the respective materials, but upon a mechanical advantage in the cup, which is afforded by the inferior degree of fulibility in the wax; and that, to obtain this valuable object, one of the following effects must be produced: Either the tallow must be burned in a lamp, to avoid the gradual progression of the flame along the wick; or fome means must be devifed to enable the candle to fnuff itself, as the wax candle does; or, lastly, the tallow itself must be rendered less fusible by some chemical process. I have no great reason to boast of success in the endeavour to effect these; but my hope is, that the facts and observations here prefented may confiderably abridge the labour of others in the same pursuit.

"The makers of thermometers and other small articles with the blow-pipe and lamp, give the preference to tallow instead of oil, because its combustion is more complete, and does not blacken the glass. In this operation the heat of the lamp melts the tallow which is occasionally brought into its vicinity by the workman. But for the usual purposes of illumination, it cannot be fupposed that a person can attend to supply the combustible matter. Considerable difficulties arise in the project for affording this gradual fupply as it may be wanted. A cylindrical piece of tallow was inferted into a metallic tube, the upper aperture of which was partly closed by a ring, and the central part occupied by a metallic piece nearly refembling that part of the common lamp which carries the wick. In this apparatus the piece last described was intended to answer the fame purpose, and was provided with a short wick. The cylinder of tallow was supported beneath in such a manner that the metallic tube and other part of this lamp were left to rest with their whole weight upon the tallow at the ring or contraction of the upper aperture. In this fituation the lamp was lighted. It burned for fome time with a very bright clear flame, which, when compared with that of a candle, possessed the advantage of uniform intenfity, and was much superior to the ordinary flame of a lamp in its colour, and the perfect absence of smell. After some minutes it began to decay, and very foon afterwards went out. Upon exacarried the wick had fused a sufficient quantity of tallow for the supply during the combustion; that part of remote parts of the apparatus, beyond the influence of able degree of folidity to the candle, and prevents its

cylinder of tallow were fastened together, and the expected progression of supply prevented. It seems probable, that in every lamp for burning confiltent oils, the material ought to be fo disposed that it may descend to the flame upon the principle of the fountain reservoir. I shall not here state the obstacles which present themselves in the prospect of this construction, but shall dismiss the subject by remarking, that a contrivance of this nature would be of the greatest public utility.

"The wick of a candle being furrounded by the flame, is nearly in the fituation of a body exposed to destructive distillation in a close vessel. After losing its volatile products, the carbonaceous refidue retains its figure, until, by the descent of the flame, the external air can have access to its upper extremity. But, in this case, the requisite combustion, which might snuff it, is not effected: for the portion of oil emitted by the long wick is not only too large to be perfectly burned, but also carries off much of the heat of the flame while it assumes the elastic state. By this diminished combustion and increased efflux of half-decomposed oil, a portion of coal or foot is deposited on the upper part of the wick, which gradually accumulates, and at length assumes the appearance of a fungus. The candle does not then give more than one-tenth of the light emitted in its best state. Hence it is that a candle of tallow cannot fpontaneously snuff itself. It was not probable that the addition of a substance containing vital air or oxygene would supply that principle at the precise period of time required; but as experiment is the test of every probability of this nature, I foaked a wick of cotton in a folution of nitre, then dried it, and made a candle. When this came to be lighted, nothing remarkable happened for a short time; at the expiration of which a decrepitation followed at the lower extremity of the flame, which completely divided the wick where the blackened part commences. The whole of the matter in combustion therefore fell off, and the candle was of course instantly extinguished. Whether this would have happened in all proportions of the falt or constructions of the candle I did not try, because the fmell of azote was sufficiently strong and unpleasant to forbid the use of nitre in the pursuit. From various confiderations I am disposed to think that the spontaneous snuffing of candles made of tallow, or other fusible materials, will scarcely be effected but by the discovery of fome material for the wick which shall be voluminous enough to absorb the tallow, and at the same time sufficiently flexible to bend on one fide.

"The most promising speculation respecting this most useful article, seems to direct itself to the cup which contains the melted tallow. The imperfection of this part has already been noticed, namely, that it breaks down by fusion, and suffers its fluid contents to escape. The Chinese have a kind of candle about half an inch in diameter, which, in the harbour of Canton, is called a lobchock; but whether the name be Chinese, or the corruption of some European word, I am ignorant. The wick is of cotton, wrapped round a small flick or mination, it was found that the metallic piece which match of the bamboo cane. The body of the candle is white tallow; but the external part, to the thickness of perhaps one thirtieth of an inch, confilts of a waxy this tallow had flowed beneath the ring, and to other matter coloured red. This covering gives a confider-

Candle. guttering, because less fusible than the tallow itself. did not observe that the slick in the middle was either advantageous or the contrary; and as I now write from the recollection of this object at fo remote a period as 25 years ago, I can only conjecture that it might be of advantage in throwing up a lefs quantity of oil into the flame than would have been conveyed by a wick of cotton fufficiently flout to have occupied its place un-

A

supported in the axis of the candle.

"Many years ago I made a candle in imitation of the lobehock. The expedient to which I had recourse confifted in adapting the wick in the usual pewter mould: wax was then poured in, and immediately afterwards poured out: the film of wax which adhered to the inner furface of the mould foon became cool, and the candle was completed by filling the mould with tallow. When it was drawn out, it was found to be cracked longitudinally on its furface, which I attributed to the contraction of the wax, by cooling, being greater than that of the tallow. At prefent I think it equally probable that the cracking might have been occasioned by too sudden cooling of the wax before the tallow was poured in; but other avocations prevented the experiments from being varied and repeated. It is probable that the Chinese external coating may not be formed of pure hard bleached wax.

"But the most decisive remedy for the impersection of this cheapest, and in other respects best material, for candles, would undoubtedly be to diminish its fusibility. Various substances may be combined with tallow, either in the direct or indirect method. In the latter way, by the decomposition of soap, a number of experiments were made by Berthollet, of which an account is inferted in the Memoirs of the Academy at Paris for the year 1780, and copied into the 26th volume of the Fournal de Physique. None of these point directly to the present object; besides which, it is probable that the foap made use of by that eminent chemist was formed not of tallow, but oil. I am not aware of any regular feries of experiments concerning the mutual action of fat oils and other chemical agents, more especially fuch as may be directed to this important object of diminishing its solubility; for which reason I shall mention a few experiments made with this view.

1. Tallow was melted in a fmall filver veffel. Solid tallow finks in the fluid, and diffolves without any remarkable appearance. 2. Gum fandarach in tears was not dissolved, but emitted bubbles, swelled up, became brown, emitted fumes, and became crisp or friable. No felution nor improvement of the tallow. 3. Shell-lac swelled up with bubbles, and was more perfectly sused than the gum fandarach in the former experiment. When the tallow was poured off, it was thought to congeal rather more speedily. The lac did not appear to be altered. 4. Benzoin bubbled without much fwelling, was fused, and emitted fumes of an agreeable smell, though not resembling the flowers of benzoin. A slight or partial folution feemed to take place. The benzoin was fofter and of a darker colour than before, and the tallow less confistent. 5. Common resin unites very readily with melted tallow, and forms a more fufible compound than the tallow itself. 6. Camphor melts eafily in tallow, without altering its appearance. When the tallow is near boiling, camphoric fumes fly off.

The compound appeared more fufible than tallow. Candla 7. The acid or flowers of benzoin diffolves in great quantities without any ebullition or commotion. Much fmoke arises from the compound, which does not fmell like the acid of benzoin. Tallow alone does not fume at a low heat, though it emits a fmell fomething like that of oil olive. When the proportion of the acid was confiderable, small needled crystals appeared as the temperature diminished. The appearances of separation are different according to the quantity of acid. The compound has the hardness and confishence of firm foap, and is partially transparent. 8. Vitriolated tartar, nitre, white fugar, cream of tartar, crystallized borax, and the falt fold in the markets under the name of falt of lemons, but which is supposed to be the effential falt of forrel, or vegetable alkali fuperfaturated with acid of fugar, were respectively tried without any obvious mutual action or change of properties in the tallow. 9. Calcined magnefia rendered tallow opaque and turbid, but did not feem to diffolve. Its effect resembled that

"It is proposed to try the oxygenated acetous acid, or radical vinegar; the acid of ants, of lugar, of borax, of galls, the tanning principle, the ferous and gelatinous animal matter, the fecula of vegetables, vegetable pluten, bird-lime, and other principles, either by direct or indirect application. The object, in a commercial point of view, is entitled to an extensive and affiduous investigation. Chemists in general suppose the hardness or less fusibility of wax to arise from oxygen; and to this object it may perhaps be advantageous to direct a certain portion of the inquiry. The metallic falts and calces are the combinations from which this principle is most commonly obtained; but the combinations of these with fat oils have hitherto afforded little promife of the improvement here fought. The subject is, however, so little known, that experiments of the loofest and most conjectural kind are by no means to be despised."

Thus far Mr Nicholson: but it is probable that many of the advantages which he propofes by these mixtures might be obtained merely by purifying the tallow, and keeping it in that state for a long time exposed to the air before it be formed into candles. It is certain that tallow is rendered more difficult of fusion by age; and this is the fole reason that old candles are less apt to run, and therefore more valuable than fuch as have

been lately made.

CANONGOES, in Bengal, are the registers of land and hereditary expounders of the usages of the country. They have their officers and deputies everywhere; they are not liable to removal; and all papers attested by them are received as authentic and decifive, in all difputes relative to lands and their boundaries. See Sir Charles Rouse Boughton's Dissertation on the Landed

Property of Bengal.

CAOUTCHOUC, ELASTIC GUM, or Indian Ruliber, is a substance of which a pretty full account has been given in the Encyclopædia. It has there been likewife observed how useful it might be, if we could form it into catheters and other flexible instruments, by dissolving it in a menstruum less expensive, or at least more easily attained, than ether. Since that article was published, we have seen an account of such a menstruum in the Annales de Chimie, by M. Groffart (Chirly);

are and of the expence of that menstruum, or the difficulty of procuring it, no complaint will be made, when it is known to be nothing more than very hot water.

The author was led to this discovery by some experiments made with ether on caoutchouc; of which he

gives the following account:

" It appeared, even in my first experiments, that I was attempting too much, and giving myfelf ufelefs trouble, in fearching for a manner of completely disfolving the elastic gum, fo that it might be again made up in new forms. I then thought that it would be easier to find out a method, as it were, of foldering it, and of not acting upon it more than might be necessary to canse its softened parts to reunite. Experience has shewn me, that a strong pressure made upon two pieces of caoutchouc (when brought to that state of foftness), and continued until they are entirely dry, caused them to contract fo strong an adhesion, that the piece, being pulled out till it broke, often broke, not at the united part, but by the fide of it.

"By means of ether I immediately fucceeded in making these tubes. The method which appears to me to succeed the best is, to cut a bottle circularly in a spiral flip of a few lines in breadth. It is very eafy to cut a bottle in fuch a manner as to form a fingle long flip,

and thus unnecessary joinings are avoided.

"The whole flip is to be plunged into ether, until it is sufficiently softened, which comes to pass sooner or later according to the quality of the vitriolic ether that is employed. Half an hour frequently fuffices; but I have already observed, that there is a great diversity in the manner in which different forts of vitriolic ether act, and of which the cause is not yet, so far as I know, determined.

"The flip being taken out, one of the extremities is to be taken hold of and rolled, first upon itself at the bottom of the tube, preffing it; then the rolling is to be continued, mounting fpirally along the mould, and taking care to lay over and compress with the hand every edge, one against the other, fo that there may not be any vacant space, and that all the edges may join exactly. The whole then is to be bound hard with a tape of an inch in width, taking care to turn it the fame way with the flip of elaftic gum. The tape is to be tied up with packthread, fo that, by every turn of the packthread joining another, an equal preffure is given to every part: it is then left to dry, and the tube is made.

"The bandage is to be taken off with great care, that none of the outward furfaces, which may have been lodged within the hollows of the tape (of which the caoutchouc takes the exact impression), may be pulled away. I advise the application of a tape before pack thread, because, especially in the thinner tubes, we should run the risk of cutting the caoutchoue, if the packthread

were applied immediately upon it.

" It is easy to take off the tube of elastic gum which has been formed upon a folid mould of one piece; if the mould be made rather conic, it may be made to flide off by the smaller end; at the worst, it is easily accomplished by plunging it into hot water; for it is foftened by the heat, and is distended; without this precaution it would be sometimes difficult to draw it off when dry, because, having been applied upon the mould whilst it had its volume augmented by the interposition

of the ether, the parts of the caoutchoug are drawn Caoutnearer each other by the evaporation of the interpoled, chouce

"The great affinity between these two bodies is seen by the length of time that the odour of the ether remains, notwithstanding the great volatility of the latter, and that the apparent dryness of the tube seems to shew that there is none remaining; nevertheless, after a certain time, the odour disappears entirely. One of those tubes, which was made with ether after the method here described, does not retain the least trace of the folvent. It is needless to fay, that it is easy to make tubes

as thin or as thick as may be judged proper.

" Although the process that I am now describing is but very little expensive, yet I have tried to employ other folvents in lieu of ether, because it is not to be had in every place, and requires particular care in its prefervation. I have employed, with fome fuccels, the effential oils of lavender and of turpentine: both of them fpeedily dilate the caoutchone, and are of no great price. The difagreeable fmell of the oil of turpentine becomes, perhaps, in process of time, less disagreeable than that of avender. This last is dearer; but the difference is not so great as it appears at first: for we may make some advantage of the oil of lavender that is employed by the following operation: Upon plunging into alcohol the elastic tube prepared with the oil of lavender, the alcohol charges itself with the oil, and forms a very good lavender-water; the fame as would be made by an immediate mixture of oil of lavender with spirit of wine. Immersion in this liquor also serves to hasten the drying of the caoutchouc instruments thus made by means of effential oils. I have made tubes with the oils of turpentine and of lavender; both are much flower in evaporating than ether. The oil of turpentine particularly appeared to me always to have a kind of flickiness, and I know not as yet that we have any means whereby to get speedily rid of its

" Nevertheless there is a solvent which has not that inconvenience; it is cheaper, and may eafily be procured by every one: this folvent is water. I conceive it will appear strange to mention water as a solvent of elaftic gum, that liquid having been always supposed to have no action upon it. I myself refisted the idea; but reflecting that ether, by being faturated with water, is the better enabled to act on caoutchouc, and that this gum when plunged into boiling water becomes more transparent at the edges, I presumed that this effect was not due simply to the dilatation of its volume by the heat. I thought that, at that temperature, fome action might take place, and that a long-continued ebullition might produce more fensible effects. I was not disappointed in my expectations, and one of those tubes was prepared without any other folvent than water and heat. I proceeded in the fame manner as with ether: the elastic gum dilates but very little in boiling water; it becomes whitish, but recovers its colour again by drying it in the air and light. It is fufficiently prepared for use when it has been a quarter of an hour in boiling water: by this time its edges are fometimes transparent. It is to be turned spirally round the mould, in the manner we described before, and replunged frequently into the boiling water, during the time that is employed in forming the tube, to the end that the edges may be disposed.

disposed to unite together. When the whole is bound with packthread, it is to be kept some hours in boiling water; after which it is to be dried, still keeping on the binding.

" If we wish to be more certain that the connection is perfect, the spiral may be doubled; but we must always avoid placing the exterior furfaces of the slips one upon the other, as those surfaces are the parts which most resist the action of solvents. This precaution is less necessary when ether is employed, on account of its

great action upon the caoutchouc.

"It might be feared that the action of water upon caontchouc would deprive us of the advantages which might otherwise be expected; but these fears will be removed, if we consider that the affinities differ according to the temperatures; that it is only at a very high temperature that water exercises any sensible action upon caoutchouc. I can affirm, that at 1200 of Reaumur's thermometer (302° of Fahrenheit) this affinity is not fuch as that the water can give a liquid form to caoutchouc; and it does not appear that we have any thing to fear in practice from a combination between these two bodies, which, though it really is a true folution, does not take place in any fenfible degree but at a high temperature. It is therefore at present easy to make of caoutchouc whatever instruments it may be advantageous to have of a flexible, supple, and elastic substance, which is impermeable to water at the temperature of our atmosphere, and resists the action of acids as well as that of most other folvents. As to the durability of these instruments, few substances promise more than this, because it may be soldered afresh in a damaged part. Any woven substance may be covered with it; it is only required that the fubstance should be of a nature not to be acted upon during the preparation, either by ether or by boiling water; for these two agents are those which appear to me to merit the preference. Artifts will frequently find an advantage in employing ether, as it requires less time; fo that a person may make, in a fingle day, any tube he may have occasion for. The expence of ether is very little, fince it is needful only to dispose the caoutchouc to adhere; and being brought into that state, the caoutchouc may be kept in a vessel perfectly well closed. It would also diminish the expence of the ether if, instead of washing it with a large quantity of water, there should be added to it only as much water as it can take up."

CAP and BUTTON, are two small islands, or rather rocks, lying in longitude 105° 48' 30" east; and in latitude, the former 5° 58' 30", the latter 5° 49' fouth. They were vifited by some of the persons attending Lord Macartney on his embaffy to China; and are thus

described by Sir George Staunton.

"At a little distance they might be mistaken for the remains of old castles, mouldering into heaps of ruins, with tall trees already growing upon the tops; but at a nearer view, they betrayed evident marks of a volcanic origin. Explosions from subterraneous fires, produce, for the most part, hills of a regular shape, and terfurface of the fea, the materials; falling back into the as in the inflance of Amsterdam, and of those smaller neous vapours. The swallow, which builds those nests,

spots called, from some resemblance in shape, the Cap Cap. and Button.

"In the Cap were found two caverns, running horizontally into the fide of the rock; and in these were a number of those birds nests so much prized by the Chinesc epicures. They seemed to be composed of fine filaments cemented together by a transparent viscous matter, not unlike what is left by the foam of the fea upon stones alternately covered by the tide, or those gelatinous animal substances found floating on every coast. The nests adhere to each other, and to the sides of the cavern, mostly in rows, without any break or interrruption. The birds that build these nests are small grey fwallows, with bellies of a dirty white. They were flying about in confiderable numbers; but they were fo fmall, and their flight fo quick, that they escaped the shot fired at them. The same nests are said also to be found in deep caverns, at the foot of the highest mountains in the middle of Java, and at a distance from the fea, from which the birds, it is thought, derive no materials, either for their food or the construction of their nests; as it does not appear probable they should fly, in fearch of either, over the intermediate mountains, which are very high, or against the boisterous winds prevailing thereabouts. They feed on infects, which they find hovering over stagnated pools between the mountains, and for catching which their wide opening beaks are particularly adapted. They prepare their nests from the best remnants of their food. Their greatest enemy is the kite, who often intercepts them in their passage to and from the caverns, which are generally furrounded with rocks of grey, limestone or white marble. The nefts are placed in horizontal rows at different depths, from 50 to 500 feet. The colour and value of the nests depend on the quantity and quality of the infects caught, and perhaps also on the situation where they are built. Their value is chiefly determined by the uniform fineness and delicacy of their texture; those that are white and transparent being most esteemed, and fetching often in China their weight in filver. These nests are a considerable object of traffic among the Javanese, and many arc employed in it from their infancy. The birds having spent near two months in preparing their nofts, lay each two eggs, which are hatched in about fifteen days. When the young birds become fledged, it is thought time to feize upon their nests, which is done regularly thrice a-year, and is effected by means of ladders of bamboo and reeds, by which the people descend into the cavern; but when it is very deep, rope ladders are preferred. This operation is attended with much danger; and feveral break their necks in the attempt. The inhabitants of the mountains generally employed in it begin always by facrificing a buffalo; which cuitom is constantly observed by the Javanese on the eve of every extraordinary enterprife. They also pronounce some prayers, anoint themselves with sweet-scented oil, and smoke the entrance of the cavern with gum-benjamin. Near some of those caverns a tutelar goddess is worshipped, whose minating in truncated cones; but when from a fub- prieft burns incense, and lays his protecting hands on aqueous volcano eruptions are thrown up above the every person preparing to descend into the cavern. A flambeau is carefully prepared at the fame time, with a water, are more irregularly differfed, and generally gum which exudes from a tree growing in the vicinity, leave the fides of the new creation naked and mifhapen, and is not eafily extinguished by fixed air or subtena-

is described as not having its tail feathers marked with times to the constellation Capricorn. Some again rewhite spots, which is a character attributed to it by Linnæus; and it is possible that there are two species or varieties of the swallow, whose nests are alike valuable." particularly Roof and STRENGTH of Materials. From these propositions we hope to deduce such principles as shall enable an attentive reader to comprehend distinctly what is to be aimed at in framing timber, and how to attain this object with certainty: and we shall illustrate and confirm our principles by examples of pieces of carpentry which are acknowledged to be excellent in

Composifol tion of forces

Vilustrated

The most important proposition of general mechanics tion and re-to the carpenter is that which exhibits the composition and refolution of forces; and we beg our practical readers to endeavour to form very diffinct conceptions of it, and to make it very familiar to their mind. When accommodated to their chief purpofes, it may be thus

expressed:

1. If a body, or any part of a body, be at once pref-Plate VIII. fed in the two directions AB, AC (fig. 1.), and if the intentity or force of those pressures be in the proportion of these two lines, the body is affected in the fame manner as if it were pressed by a single force acting in the direction AD, which is the diagonal of the parallelogram ABDC formed by the two lines, and whose intensity has the same proportion to the intensity of each of the other two that AD has to AB or AC.

Such of our readers as have fludied the laws of motion, know that this is fully demonstrated. We refer them to the article MECHANICS, n° 5, &c. where it is treated at some length. Such as wish for a very accurate view of this proposition, will do well to read the demonstration given by D. Bernoulli, in the first volume of the Comment. Petropol. and the improvement of this demonstration by D'Alembert in his Opuscles, and in the Comment. Taurinens. The practitioner in carpentry will get more useful confidence in the doctrine, if he will shut his book, and verify the theoretical demonstrations by actual experiments. They are remarkably easy and convincing. Therefore it is our request that the artist, who is not so habitually acquainted with the subject, do not proceed further till he has made it quite familiar to his thoughts. Nothing is fo conducive to this as the actual experiment; and fince this only requires the trifling expence of two small pulleys and a few yards of whipcord, we hope that none of our practical readers will omit it: They will thank us for

this injunction.

2. Let the threads Ad, AFb, and AEc (fig. 2.), have the weights d, b, and c, appended to them, and let two of the threads be laid over the pulleys F and E. By this apparatus the knot A will be drawn in the directions AB, AC, and AK. If the fum of the weights b and c be greater than the fingle weight d, the affemblage will of itself settle in a certain determined form; if you pull the knot A out of its place, it will always return to it again, and will rest in no other position. For example, if the three weights are equal, the threads will always make equal angles, of 120 degrees each, round the knot. If one of the weights be three pounds, another four, and the third five, the angle opposite to the thread firetched by five pounds will always be fquare, &c. When the knot A is thus in equilibrio, we must infer, that the action of the weight d, in the direction A d, is in direct opposition to the combined action of b, in the direction AB, and of c, in the direction AC. Therefore, if we produce dA to any point D, and take AD to represent the magnitude of the force, or

pressure exerted by the weight d, the pressures exerted on A by the weights b and c, in the directions AB. AC, are in fact equivalent to a pressure acting in the direction AD, whose intensity we have represented by AD. If we now measure off by a scale on AF and AE the lines AB and AC, having the same proportions to AD that the weights b and c have to the weight d, and if we draw DB and DC, we shall find DC to be equal and parallel to AB, and DB equal and parallel to AC; fo that AD is the diagonal of a parallelogram ABDC. We shall find this always to be the case, whatever are the weights made use of; only we must take care that the weight which we cause to act without the intervention of a pulley be less than the fum of the other two: if any one of the weights exceeds the fum of the other two, it will prevail, and drag them along with it.

Now, fince we know that the weight d would just balance an equal weight g, pulling directly upwards by the intervention of the pulley G; and fince we see that it just balances the weights b and c, acting in the directions AB, AC, we must infer, that the knot A is affected in the same manner by those two weights, or by the single weight g; and therefore, that two pressures, acting in the directions, and with the intensities, AB, AC, are equivalent to a single pressure having the direction and proportion of AD. In like manner, the pressures AB, AK, are equivalent to AH, which is equal and opposite to AC. Also AK and AC are equivalent to

AI, which is equal and opposite to AB.

We shall consider this combination of pressures a little Consider more particularly.

Suppose an upright beam BA (fig. 3.) pushed in cularly, the direction of its length by a load B, and abutting on the ends of two beams AC, AD, which are firmly refifted at their extreme points C and D, which rest on two blocks, but are nowife joined to them: thefe two beams can refift no way but in the directions CA, DA; and therefore the pressures which they sustain from the beam BA are in the directions AC, AD. We wish to know how much each fultains? Produce BA to E, taking AE from a scale of equal parts, to represent the number of tons or pounds by which BA is preffed. Draw EF and EG parallel to AD and AC; then AF, measured on the same scale, will give us the number of pounds by which AC is strained or crushed, and AG will give the strain on AD.

It deferves particular remark here, that the length of AC or AD has no influence on the strain, arifing from the thrust of BA, while the directions remain the fame. The effects, however, of this strain are modifyed by the length of the piece on which it is exerted. This strain compresses the beam, and will therefore compress a beam of double length twice as much. This may change the form of the assemblage. If AC, for example, be very much shorter than AD, it will be much less compressed: The line CA will turn about the centre C, while DA will hardly change its position; and the angle CAD will grow more open, the point A finking down. The artist will find it of great consequence to pay a very minute attention to this circumftance, and to be able to fee clearly the change of shape which neceffarily results from these mutual strains. He will see in this the cause of failure in many very great works .--By thus changing shape, strains are often produced in

places

places where there were none before, and frequently of artist have any doubts of AC' being on the stretch, if the very worst kind, tending to break the beams across.

of the beam AD'. This makes a prodigious change, not only in the firain on AD', but also in that on AC. Both of them are much increased; AG is almost doubled, and AF is four times greater than before. This addition was made to the figure, to shew what enormous firains may be produced by a very moderate force AE, when it is exerted on a very obtuse angle.

The 4th and 5th figures will affift the most uninstructed reader in conceiving how the very fame strains AF, AG, are laid on these beams, by a weight simply hanging from a billet refting on A, preffing hard on AD, and also leaning a little on AC; or by an unright piece AE, joggled on the two beams AC, AD, and performing the office of an ordinary king-post. The reader will thus learn to call off his attention from the means by which the strains are produced, and learn to consider them abstractedly, merely as strains, in whatever situation he finds them, and from whatever cause they arise.

We prefume that every reader will perceive, that the proportions of these strains will be precisely the same if every thing be inverted, and each beam be drawn or pulled in the opposite direction. In the same way that we have substituted a rope and weight in fig. 4. or a king-post in fig. 5. for the loaded beam BA of fig. 3. we might have substituted the framing of fig. 6. which is a very usual practice. In this framing, the batten DA is stretched by a force AG, and the piece AC is compressed by a force AF. It is evident, that we may employ a rope, or an iron rod hooked on at D, in place of the batten DA, and the strains will be the same as before.

This feemingly fimple matter is still full of instruction; and we hope that the well-informed reader will pardon us, though we dwell a little longer on it for the

fake of the young artist.

By changing the form of this framing, as in fig. 7. we produce the same strains as in the disposition represented by the dotted lines in fig. 3. The strains on both the battens AD, AC, are now greatly increased.

The same consequences result from an improper change of the position of AC. If it is placed as in fig. 8, the strains on both are vastly increased. In short, the rule is general; that the more open we make the angle against which the push is exerted, the greater are the strains which are brought on the struts or ties which form the fides of the angle.

The reader may not readily conceive the piece AC of fig. 8. as fultaining a compression; for the weight B appears to hang from AC as much as from AD. But his doubts will be removed by confidering whether he could employ a rope in place of AC. He cannot: But AD may be exchanged for a rope. AC is there-

fore a strut, and not a tie.

In fig. 9. AD is again a strut, butting on the block D, and AC is a tie; and the batten AC may be replaced by a rope. While AD is compressed by the force AG, AC is firetched by the force AF.

If we give AC the polition represented by the dotted lines, the compression of AD is now AG', and the force flietching AC' is now Al"; both much greater than they were before. This disposition is analogous to fig. 8. and to the dotted lines in fig. 3. Nor will the young

SUPPL. VOL I. Part I.

he consider whether AD can be replaced by a rope. The dotted lines of this figure shew another position It cannot, but AC may; and it is therefore not compressed, but stretched.

In fig. 10. all the three pieces, AC, AD, and AB, are ties, on the stretch. This is the complete inversion of fig. 3.; and the dotted position of AC induces the

fame changes in the forces AF, AG', as in fig. 3.

Thus have we gone over all the varieties which can happen in the bearings of three pieces on one point. All calculations about the strength of carpentry are reduced to this case: for when more ties or braces meet in a point (a thing that rarely happens), we reduce them to three, by fubflituting for any two the force which refults from their combination, and thea combining this with another; and fo on.

The young artist must be particularly careful not to mistake the kind of strain that is exerted on any piece of the framing, and suppose a piece to be a brace which is really a tie. It is very easy to avoid all mistakes in this matter by the following rule, which has no excep-

Take notice of the direction in which the piece acts Rule for from which the strain proceeds. Draw a line in that distinguish. direction from the point on which the strain is exerted; ing the caand let its length (measured on some scale of equal pression and parts) express the magnitude of this action in pounds, extension. hundreds, or tons. From its remote extremity draw lines parallel to the pieces on which the strain is exerted. The line parallel to one piece will necessarily cut the other, or its direction produced: If it cut the piece itself, that piece is compressed by the strain, and it is performing the office of a strut or brace: if it cut its direction produced, the piece is thretched, and it is a tie. In short, the strains on the pieces AC, AD, are to be estimated in the direction of the points F and G from the strained point A. Thus, in fig 3. the upright piece BA, loaded with the weight B, preffes the point A in the direction AE: so does the rope AB in the other figures, or the batten AB in fig. 5.

In general, if the straining piece is within the angle formed by the pieces which are strained, the strains which they sustain are of the opposite kind to that which it exerts. If it be pushing, they are drawing; but if it be within the angle formed by their directions produced, the strains which they sustain are of the same kind. All the three are either drawing or preffing. If the straining piece lie within the angle formed by one piece and the produced direction of the other, its own strain, whether compression or extension, is of the same kind with that of the most remote of the other two, and opposite to that of the nearest. Thus, in fig. 9. where AB is drawing, the remote piece AC is also drawing, while AD is pushing or resisting compression.

In all that has been said on this subject, we have not spoken of any joints. In the calculations with which we are occupied at present, the resiltance of joints has no share; and we must not suppose that they exert any force which tends to prevent the angles from changing. The joints are supposed perfectly flexible, or to be like compass joints; the pin of which only keeps the pieces together when one or more of the pieces draws or pulls. The carpenter must always suppose them all compass joints when he calculates the thrusts and draughts of the different pieces of his frames. The strains on joints,

and their power to produce or balance them, are of a different kind, and require a very different examination. General ex- Seeing that the angles which the pieces make with pression of each other are of such importance to the magnitude and the proportion of the excited strains, it is proper to

find out fome way of readily and compendiously conceiving and expressing this analogy.

In general, the strain on any piece is proportional to

the straining force. This is evident.

Secondly, the strain on any piece AC is proportional to the fine of the angle which the straining force makes with the other piece directly, and to the fine of the angle which the pieces make with each other inverfely.

For it is plain, that the three preffures AE, AF, and AG, which are exerted at the point A, are in the proportion of the lines AE, AF, and FE (because FE is equal to AG). But because the sides of a triangle are proportional to the fines of the opposite angles, the strains are proportional to the fines of the angles AFE, AEF, and FAE. But the fine of AFE is the same with the fine of the angle CAD, which the two pieces AC and AD make with each other; and the fine of AEF is the same with the sine of EAD, which the straining piece BA makes with the piece AC. Therefore we have this analogy, Sin. CAD : Sin. EAD =

AE : AF, and $AF = AE \times \frac{Sin. EAD}{Sin. CAD}$. -Now the

fine of angles are most conveniently conceived as decimal fractions of the radius, which is confidered as unity. Thus, Sin. 30° is the fame thing with 0,5, or ½; and fo of others. Therefore, to have the strain on AC, arifing from any load AE acting in the direction AE, multiply AE by the fine of EAD, and divide the product by the fine of CAD.

This rule shews how great the strains must be when the angle CAD becomes very open, approaching to 180 degrees. But when the angle CAD becomes very fmall, its fine (which is our divisor) is also very small; and we should expect a very great quotient in this case also. But we must observe, that in this case the fine of EAD is also very small; and this is our multiplier. In such a case, the quotient cannot exceed unity.

But it is unnecessary to consider the calculation by the tables of fines more particularly. The angles are feldom known any otherwise but by drawing the figure of the frame of carpentry. In this case, we can always obtain the measures of the strains from the same scale, with equal accuracy, by drawing the parallelo-

gram AFCG.

Strains proof fupport.

Hitherto we have confidered the strains excited at pagated to A only as they affect the pieces on which they are exthe points erted. But the pieces, in order to sustain, or be subject to, any strain, must be supported at their ends C and D; and we may confider them as mere intermediums, by which these strains are made to act on those points of support: Therefore AF and AG are also meafures of the forces which press or pull at C and D. Thus we learn the supports which must be found for these points. These may be infinitely various. We shall attend only to such as somehow depend on the framing itself.

Such a structure as fig. 11. very frequently occurs, Action of a where a beam BA is strongly pressed to the end of an-Araining beam. both because it lies on another beam HD; and because

its end D is hindered from fliding backwards. It is indifferent from what this pressure arises: we have represented it as owing to a weight hung on at B, while B is withheld from yielding by a rod or rope hooked to the wall. 'I'he beam AD may be supposed at full liberty to exert all its pressure on D, as if it were supported on rollers lodged in the beam HD; but the loaded beam BA presses both on the leam AD and on HD. We wish only to know what strain is borne by AD?

All bodies act on each other in the direction perpendicular to their touching furfaces; therefore the fupport given by HD is in a direction perpendicular to it. We may therefore supply its place at A by a beam AC, perpendicular to HD, and firmly supported at C. In this case, therefore, we may take AE, as before, to represent the pressure exerted by the loaded beam, and draw EG perpendicular to AD, and EF parallel to it, meeting the perpendicular AC in F. Then AG is the ftrain compressing AD, and AF is the pressure on the beam HD.

It may be thought, that fince we assume as a prin-The form ciple that the mutual pressures of solid bodies are exert of the all ed perpendicular to their touching furfaces, this ba-ting joint lance of pressures, in framings of timbers, depends on importthe directions of their butting joints: but it does not, ance. as will readily appear by confidering the prefent cafe. Let the joint or abutment of the two pieces BA, AD be mitred, in the usual manner, in the direction f A fi. Therefore, if A e be drawn perpendicular to A f, it will be the direction of the actual pressure exerted by the loaded beam BA on the beam AD. But the reaction of AD, in the opposite direction At, will not balance the pressure of BA; because it is not in the direction precifely opposite. BA will therefore slide along the joint, and press on the beam HD. AE represents the load on the mitre joint A. Draw E e perpendicular to Ae, and Ef parallel to it. The preffure AE will be balanced by the reactions e A and fA: or, the pressure AE produces the pressures A e and A f: of which Af must be resisted by the beam HD, and A e by the beam AD. The pressure Af not being perpendicular to HD, cannot be fully refifted by it; because (by our assumed principle) it reacts only in a direction perpendicular to its furface. Therefore draw fp, fi parallel to HD, and perpendicular to it. The pressure Af will be resisted by HD with the force pA; but there is required another force i A, to prevent the beam BA from flipping outwards. This muff be furnished by the reaction of the beam DA .- In like manner, the other force A e cannot be fully refifted by the beam AD, or rather by the prop D, acting by the intervention of the beam; for the action of that prop is exerted through the beam in the direction DA. The beam AD, therefore, is pressed to the beam HD by the force Ae, as well as by Af. To find what this preffure on HD is, draw eg perpendicular to HD, and eo parrallel to it, cutting EG in r. The forces g A and o A will refift, and balance A e.

Thus we see, that the two forces A e and A f, which are equivalent to AE, are equivalent also to Ap, Ai, A o, and Ag. But because Af and e E are equal and parallel, and Er and fi are also parallel, as also er and other beam AD, which is prevented from yielding, fp, it is evident, that if is equal to r E, or to o F, and i A is equal to re, or to Gg. Therefore the four forces

Ag, Ao, Ap, Ai, are equal to AG and AF. There- angles of which they are composed, as will appear more fore AG is the compression of the beam AD, or the force preffing it on D, and AF is the force preffing it on the beam HD. The proportion of these pressures, therefore, is not affected by the form of the joint.

This remark is important; for many carpenters think the form and direction of the butting joint of great importance; and even the theorist, by not profecuting the general principle through all its consequences, may be led into an error. The form of the joint is of no importance, in as far as it affects the strains in the direction of the beams; but it is often of great confequence, in respect to its own firmness, and the effect it may have in bruifing the piece on which it acts, or being crippled by it.

The fame compression of AB, and the fame thrust on frain the point D by the intervention of AD, will obtain, in whatever way the original pressure on the end A is produced. Thus supposing that a chord is made fast at A, and pulled in the direction AE, and with the fame force, the beam AD will be equally compressed, and

the prop D must react with the same force.

But it often happens that the obliquity of the pressure on AD, instead of compressing it, stretches it; and we defire to know what tension it sustains. Of this we have a familiar example in a common roof. Let vertically on the ridge A, as if a weight B were hung on there. We may represent this weight by the portween the ridge and the beam. Then drawing b f and bg parallel to AD and AC, Ag and Af will represent the pressures on AC and AD. Produce AC till CH be equal to A f. The point C is forced out in this dithis force is not perpendicularly across the beam, it evidently stretches it; and this extending force must be withstood by an equal force pulling it in the opposite direction. This must arise from a similar oblique thrust of the opposite rafter on the other end D. We concern ourselves only with this extension at present; but we fee that the cohefion of the beam does nothing but supply the balance to the extending forces. It must flill be supported externally, that it may resist, and, by refifting obliquely, be stretched. The points C and D are supported on the walls, which they press in the directions CK and DO, parallel to A b. If we draw HK parallel to DC, and HI parallel to CK (that is, to Ab), meeting DC produced in 1, it follows from the composition of forces, that the point C would be supported by the two forces KC and IC. In like manner, making DN = Ag, and completing the parallelogram DMNO, the point D would be supported by the forces OD and MD. If we draw go and fk parallel to DC, it is plain that they are equal to NO and CK, while A o and A k are equal to DO and CK, and A b is equal to the fum of DO and CK (because it is equal to $A \circ + A k$). The weight of the roof is equal to its vertical pressure on the walls.

Thus we see, that while a pressure on A, in the direction Ab, produces the strains Af and Ag, on the pieces AC and AD, it also excites a strain CI or DM in the piece DC. And this completes the mechanism of a frame; for all derive their efficacy from the triclearly as we proceed.

But there is more to be learned from this. The External consideration of the strains on the two pieces AD and action of a AC, by the action of a force at A, only shewed them frame. as the means of propagating the same strains in their own direction to the points of support. But, by adding the strains exerted in DC, we see that the frame becomes an intermedium, by which exertions may be made on other bodies, in certain directions and proportions; fo that this frame may become part of a more complicated one, and, as it were, an element of its constitution. It is worth while to ascertain the proportion of the pressures CK and DO, which are thus exerted on the walls. The fimilarity of triangles gives the following analogies:

DO:DM = Ab:bDCI, or DM : CK = Cb : AbTherefore DO: CK = Cb : bD.

Or, the pressures on the points C and D, in the direction of the straining force A b, are reciprocally proportional to the portions of DC intercepted by Ab.

Also, since A b is = DO + CK, we have Ab: CK = Cb + bD (or CD): bD, and Ab: DO = CD: bC.

In general, any two of the three parallel forces A b, the two rafters AC, AD (fig. 12.), press on the tie- DO, CK, are to each other in the seciprocal proporbeam DC. We may suppose the whole weight to press tion of the parts of CD, intercepted between their di-

rections and the direction of the third.

And this explains a still more important office of the tion A b of the vertical or plumb line, intercepted be- frame ADC. If one of the points, fuch as D, be supported, an external power acting at A, in the direction A b, and with an intensity which may be measured by A b, may be set in equilibrio, with another acting at C, in the direction CL, opposite to CK or Ab, and with rection, and with a force represented by this line. As an intensity represented by CK: for since the pressure CH is partly withstood by the force IC, or the sirmness of the beam DC supported at D, the force KC will complete the balance. When we do not attend to the support at D, we conceive the force A b to be balanced by KC, or KC to be balanced by Ab. And, in like manner, we may neglect the support or force acting at A, and consider the force DO as balanced by CK.

Thus our frame becomes a lever, and we are able to It becomes trace the interior mechanical procedure which gives it a lever. its efficacy: it is by the intervention of the forces of cohesion, which connect the points to which the external forces are applied with the supported point or fulcrum,

and with each other.

These strains or pressures A b, DO, and CK, not being in the directions of the beams, may be called tranfverse. We see that by their means a frame of carpentry may be confidered as a folid body: but the example which brought this to our view is too limited for explaining the efficacy which may be given to fuch conitructions. We shall therefore give a general proposition, which will more distinctly explain the procedure of nature, and enable us to trace the strains as they are propagated through all the parts of the most complicated framing, finally producing the exertion of its most distant points.

We presume that the reader is now pretty well habi-General tuated to the conception of the strains as they are pro-proposipagated along the lines joining the points of a frame, tion. and we shall therefore employ a very simple figure.

r3 igit of

Let the strong lines ACBD (fig. 13.) represent a frame of carpentry. Suppose that it is pulled at the point A by a force acting in the direction AE, but that it rests on a fixed point C, and that the other extreme point B is held back by a power which refifts in the direction BF: It is required to determine the proportion of the strains excited in its different parts, the proportion of the external pressures at A and B, and the pressure which is produced on the obstacle or ful-

It is evident that each of the external forces at A and B tend one way, or to one side of the frame, and that each would cause it to turn round C if the other did not prevent it; and that if, notwithstanding their action, it is turned neither way, the forces in actual exertion are in equilibrio by the intervention of the frame. It is no less evident that these forces concur in preffing the frame on the prop C. Therefore, if the piece CD were away, and if the joints C and D be perfectly flexible, the pieces CA, CB would be turned round the prop C, and the pieces AD, DB would also turn with them, and the whole frame change its form. This shews, by the way, and we defire it to be carefully kept in mind, that the firmness or stiffness of framing depends entirely on the triangles bounded by beams which are contained in it. An open quadrilateral may always change its shape, the sides revolving round the angles. A quadrilateral may have an infinity of forms, without any change of its fides, by merely pushing two oppofite angles towards each other, or drawing them afunder. But when the three fides of a triangle are determined, its shape is also invariably determined; and if two angles be held fast, the third cannot be moved. It is thus that, by inferting the bar CD, the figure becomes unchangeable; and any attempt to change it by applying a force to an angle A, immediately excites forces of attraction or repulsion between the particles of the stuff which form its sides. Thus it happens, in the present instance, that a change of shape is prevented by the bar CD. The power at A presses its end against the prop; and in doing this it puts the bar AD on the Aretch, and also the bar DB. Their places might therefore be supplied by cords or metal wires. Hence it is evident that DC is compressed, as is also AC: and, for the same reason, CB is also in a state of compression; for either A or B may be confidered as the point that is impelled or withheld. Therefore DA and DB are stretched, and are resisting with attractive forces. DC and CB are compressed, and are resisting with repulsive forces. DB is also acting with repulsive forces, being compressed in like manner: and thus the support of the prop, combined with the firmness of DC, puts the frame ADBC into the condition of the two frames in fig. 8. and fig. 9. Therefore the external force at A is really in equilibrio with an attracting force acting in the direction AD, and a repulsive force acting in the direction AK. And fince all the connecting forces are mutual and equal, the point D is pulled or drawn in the direction DA. The condition of the point B is similar to that of A, and D is also drawn in the direction DB. Thus the point D, being urged by the forces in the directions DA and DB, presses the beam DC on the prop, and the prop refilts in the opposite direction. Therefore the line DC is the diagonal of the parallelogram, whose sides have the proportion of the forces That is, the external forces are reciprocally propor-

which connect D with A and B. This is the prin. ciple on which the rest of our investigation proceeds. We may take DC as the representation and measure of their joint effect. Therefore draw CH, CG, parallel to DA, DB. Draw HL, GO, parallel to CA, CB, cutting AE, BF in L and O, and cutting DA, DB in I and M. Complete the parallelograms ILKA, MONB. Then DG and AI are the equal and oppofite forces which connect A and D; for GD = CH, = AI. In like manner DH and BM are the forces which connect D and B.

The, external force at A is in immediate equilibrio with the combined forces, connecting A with D and with C. AI is one of them: Therefore AK is the other; and AL is the compound force with which the external force at A is in immediate equilibrium. This external force is therefore equal and opposite to AL. In like manner, the external force at B is equal and opposite to BO; and AL is to BO as the external force at A to the external force at B. The prop C refifts with forces equal to those which are propagated to it from the points D, A, and C. Therefore it refists with forces CH, CG, equal and opposite to DG, DH; and it refilts the compressions KA, NB, with equal and opposite forces Ck, Cn. Draw kl, no parallel to AD, BD, and draw ClQ, CoP: It is plain that & CH / is a parallelogram equal to KAII., and that Clis equal to AL. In like manner Co is equal to BO. Now the forces Ck, CH, exerted by the prop. compose the force Cl; and Cn, CG compose the force Co. These two forces Cl, Co are equal and parallel to AL and BO; and therefore they are equal and opposite to the external forces acting at A and B. But they are (primitively) equal and opposite to the preffures (or at least the compounds of the pressures) exerted on the prop, by the forces propagated to C from A, D, and B. Therefore the pressures exerted on the prop are the same as if the external forces were applied. there in the same directions as they are applied to A and B. Now it we make CV, CZ equal to Cl and Co, and complete the parallelogram CVYZ; it is plain that the force YC is in equilibrio with IC and oC. Therefore the pressures at A, C, and B, are such as would balance if applied to one point.

Lastly, in order to determine their proportions, draw CS and CR perpendicular to DA and DB. Also draw A d, B f perpendicular to CQ and CP; and draw Cg, Ci perpendicular to AE, BF.

The triangles CPR and BPf are fimilar, having a common angle P, and a right angle at R and f.

In like manner the triangles CQS and AQ d are fimilar. Also the triangles CHR, CGS are similar, by reason of the equal angles at H and G, and the right angles at R and S. Hence we obtain the following analogies:

> $C \circ : CP = O n : PB, = CG : PB$ CP : CR = PB:fBCR : CS = CH: CG CS : CQ = Ad: AQ CQ: Cl = AQ: Kl, = AQ: CH.Therefore, by equality,

Co: Cl= Ad:fBor BO: AL= Cg: Ci.

tional to the perpendiculars drawn from the prop on creafed only in the proportion of 2 to 3; and they

tenfive

This proposition (sufficiently general for our purfequen- pose) is fertile in consequences, and furnishes many use-ful instructions to the artist. The strains LA, OB, CY, that are excited, occur in many, we may fay in all, framings of carpentry, whether for edifices or engines, and are the fources of their efficacy. It is also evident, that the doctrine of the transverse strength of timber is contained in this proposition; for every piece of timber may be considered as an assemblage of parts, connected by forces which act in the direction of the lines which join the strained points on the matter which lies between those points, and also act on the rest of the matter, exciting those lateral forces which produce the inflexibility of the whole. See STRENGTH of Materials,

Thus it appears that this proposition contains the principles which direct the artist to frame the most powerful levers; to fecure uprights by shores or braces, or by ties and ropes; to secure scaffoldings for the erection of spires, and many other most delicate problems of his art. He also learns, from this proposition, how to afcertain the strains that are produced, without his intention, by pieces which he intended for other offices, and which, by their transverse action, put his work in hazard. In short, this proposition is the key to the

science of his art.

We would now counsel the artist, after he has made the tracing of the strains and thrusts through the various parts of a frame familiar to his mind, and even amused himself with some complicated fancy framings, to read over with care the articles STRENGTH of Materials and Roof in the Encyclopædia Britannica. He will now conceive its doctrines much more clearly than when he was confidering them as abstract theories. The mutual action of the woody fibres will now be eafily comprehended, and his confidence in the refults will be greatly increased.

There is a proposition (no 19. in the article Roof) which has been called in quettion by feveral very intelliportant gent persons; and they say that Belidor has demonstrated, in his Science des Ingenieurs, that a beam firmly fixed at both ends is not twice as ftrong as when fimply lying on the props, and that its strength is in-

support this determination by a list of experiments recited by Belidor, which agree precifely with it. Belidor also says, that Pitot had the same result in his experiments. These are respectable authorities: but Belidor's reasoning is any thing but demonstration; and his experiments are described in such an imperfect manner, that we cannot build much on them. It is not faid in what manner the battens were fecured at the ends, any farther than that it was by chevalets. If by this word is meant a tressle, we cannot conceive how they were employed; but we fee it sometimes used for a wedge or key. If the battens were wedged in the holes, their resistance to fracture may be made what we please: they may be loose, and therefore resist little more than when simply laid on the props. They may be (and probably were) wedged very fast, and bruised or crippled.

Our proposition mentioned distinctly the security given to the ends of the beams. They were mortifed into remote posts. Our precise meaning was, that they were simply kept from rising by these mortises, but at full liberty to bend up between E and I, and between G and K. Our affertion was not made from theory alone (although we think the reasoning incontrovertible), but was agreeable to numerous experiments made in those precise circumstances. Had we mortised the beams firmly into two very flout posts, which could not be drawn nearer to each other by bending, the beam would have borne a much greater weight, as we have verified by experiment. We hope that the following mode of conceiving this case will remove all doubts.

Let LM be a long beam (fig. 14.) divided into fix equal parts, in the points D, B, A, C, E. Let it be firmly supported at L, B, C, M. Let it be cut thro at A, and have compass joints at B and C. Let FB, GC be two equal uprights, resting on B and C, but without any connection. Let AH be a fimilar and equal piece, to be occasionally applied at the seam A. Now let a thread or wire AGE be extended over the piece GC, and made fast at A, G, and E. Let the tame thing be done on the other fide of A. If a weight be now laid on at A, the wires AFD, AGE will be strained, and may be broken. In the instant of fracture we may suppose their strains to be represented by Af

ifion of flion.

> (A) The learned reader will perceive, that this analogy is precifely the same with that of forces which are in equilibrio by the intervention of a lever. In fact, this whole frame of carpentry is nothing else than a built or framed lever in equilibrio. It is acting in the same manner as a solid, which occupies the whole figure compressed in the frame, or as a body of any fize and shape whatever that will admit the three points of application A, C, and B. It is always in equilibrio in the case first stated; because the pressure produced at B by a force applied to A is always such as balances it. The reader may also perceive, in this proposition, the analysis or tracing of those internal mechanical forces which are indispensably requisite for the functions of a lever. The mechanicians have been extremely puzzled to find a legitimate demonstration of the equilibrium of a lever ever since the days of Archimedes. Mr Vince has the honour of first demonstrating, most ingeniously, the principle affamed by Archimedes, but without sufficient ground, for bis demonstration: but Mr Vince's demonstration is only a putting the mind into that perplexed state which makes it acknowledge the proposition, but without a clear perception of its truth. The difficulty has proceeded from the abiltract notion of a lever, conceiving it as a mathematical line-inflexible, without reflecting how it is inflexible-for the very fource of this indispensable quality furnishes the mechanical connection between the remote pressures and the fulcrum; and this supplies the demonstration (without the least difficulty) of the desperate case of a straight lever urged by parallel forces. See ROTATION, nº 11. Encycl.

and Ag. Complete the parallelogram, and Aa is the magnitude of the weight. It is plain that nothing is concerned here but the cohesion of the wires; for the beam is fawed through at A, and its parts are perfectly

movcable round B and C.

Instead of this process apply the piece AH below A, and keep it there by straining the same wire BHC over it. Now lay on a weight. It must press down the ends of BA and CA, and cause the piece AH to strain the wire BHC. In the instant of fracture of the fame wire, its refistances H b and H c must be equal to Af and Ag, and the weight bH which breaks them must be equal to A a.

Lattly, employ all the three pieces FB, AH, GC, with the same wire attached as before. There can be no doubt but that the weight which breaks all the four

wires must be = a A + b H, or twice A a.

The reader cannot but fee that the wires perform the very same office with the fibres of an entire beam LM held fast in the tour holes D, D, C, and E, of some upright posts.

In the experiments for verifying this, by breaking flender bars of fine deal, we get complete demonstration, by measuring the curvatures produced in the parts of the beam thus held down, and comparing them with the curvature of a beam simply laid on the props B and C: and there are many curious inferences to be made from these observations, but we have not room for them

in this place.

The heft marner of framing purlins.

We may observe, by the way, that we learn from this case, that purlins are able to carry twice the load when notched into the rafters that they carry when mortifed into them, which is the most usual manner of framing them. So would the binding joifts of floors; but this would double the thickness of the flooring. But this method should be followed in every possible case, such as breaft fummers, lintels over feveral pillars, &c. Thefe should never be cut off and mortised into the sides of every upright; numberless cases will occur which shew

the importance of the maxim.

We must here remark, that the proportion of the spaces BC and CM, or BC and I.B, has a very fenfible effect on the strength of the beam BC; but we have not yet satisfied our minds as to the rationale of this efeffect. It is undoubtedly connected with the ferpentine form of the curve of the beam before fracture. This should be attended to in the construction of the springs of carriages. These are frequently supported at a middle point (and it is an excellent practice), and there is a certain proportion which will give the easiest motion to the body of the carriage. We also think that it is connected with that deviation from the best theory observable in Buffon's experiments on various lengths of the fame fcantling. The force of the beams diminished much more than in the inverse proportion of their

Ties are in

Eruts.

We have feen that it depends entirely on the position general bet of the pieces in respect of their points of ultimate support, and of the direction of the external force which produces the strains, whether any particular piece is in a state of extension or of compression. The knowledge of this circumstance may greatly influence us in the choice of the construction. In many cases we may sub-stitute slender iron rods for massive beams, when the piece is to act the part of a tie. But we must not invert this disposition; for when a piece of timber acts as

a strut, and is in a state of compression, it is next to certain that it is not equally compressible in its opposite fides through the whole length of the piece, and that the compressing force on the abutting joint is not act. ing in the most equable manner all over the joint. A very trifling inequality in either of these circumstances (especially in the first) will compress the beam more on one fide than on the other. This cannot be without the beam's bending, and becoming concave on that fide on which it is most compressed. When this happens, the frame is in danger of being crushed, and foon going to ruin. It is therefore indispensably necessary to make use of beams in all cases where struts are required of considerable length, rather than of metal rods of slender dimensions, unless in situations where we can effectually prevent their bending, as in truffing a girder internally, where a cast iron strut may be firmly cased in it, so as not to bend in the smallest degree. In cases where the pressures are enormous, as in the very oblique struts of a centre or arch frame, we must be particularly cautious to do nothing which can facilitate the compression of either fide. No mortifes should be cut near to one fide; no lateral pressures, even the slightest, should be allowed to touch it. We have seen a pillar of fir 12 inches long and one inch in section, when loaded with three tons, snap in an instant when pressed on one side by 16 pounds, while another bore 41 tons without hurt, because it was inclosed (loosely) in a stout pipe of iron.

In fuch cases of enormous compression, it is of great importance that the compressing force bear equally out the whole abutting furface. The German carpenters are accustomed to put a plate of lead over the joint. This prevents, in some measure, the penetration of the end fibres. Mr Perronet, the celebrated French architect, formed his abutments into arches of circles, the centre of which was the remote end of the strut. By this contrivance the unavoidable change of form of the triangle made no partial bearing of either angle of the abutment. This always has a tendency to splinter off the heel of the beam where it presses strongest. It is a

very judicious practice.

When circumstances allow it, we should rather employ ties than struts for securing a beam against lateral strains. When an upright pillar, such as a stag staff, a mast, or the uprights of a very tall scaffolding, are to be shoared up, the dependence is more certain on those braces that are stretched by the strain than on those which are compressed. The scassolding of the iron bridge near Sunderland had some ties very judiciously disposed, and others with less judgment.

We should proceed to consider the transverse strains as they affect the various parts of a frame of carpentry; but we have very little to add to what has been faid already in the article STRENGTH of Materials (Encycl) and in the article Roof. What we shall add in this article will find a place in our occasional remarks on different works. It may, however, be of use to recal to the reader's memory the following propositions.

I When a beam AB (fig. 15.) is firmly fixed at the Genera end A, and a straining force acts perpendicularly to its theorem length at any point B, the strain occasioned at any sec-concern tion C between B and A is proportional to CB, and frengtls may therefore be represented by the product WXCB; beams. that is, by the product of the number of tons, pounds, &c. which measure the straining force, and the number

of feet, inches, &c. contained in CB. As the loads on a beam are easily conceived, we shall substitute this for

any other straining force.

2. If the frain or load is uniformly distributed along any part of the beam lying beyond C (that is, further from A), the strain at C is the same as if the load were all collected at the middle point of that part; for that point is the centre of gravity of the load.

3. The strain on any section D of a beam AB (fig. 16.) refling freely on two props A and B, is $w \times \frac{AD \times DB}{AB}$ (see Roof, n° 19. and Strength of

Materials, no 92, &c. Encycl.) Therefore,

4. The strain on the middle point, by a force applied there, is one fourth of the strain which the same force would produce, if applied to one end of a beam of the same length, having the other end fixed.

5. The strain on any section C of a beam, resting on two props A and B, occasioned by a force applied perpendicularly to another point D, is proportional to the rectangle of the exterior fegments, or is equal to

 $w \times \frac{AC \times DB}{AB}$. Therefore

The strain at C occasioned by the pressure on D, is the same with the strain at D occasioned by the same

pressure on C.

6. The strain on any section D, occasioned by a load uniformly diffused over any part EF, is the same as if the two parts ED, DF of the load were collected at their middle points e and f. Therefore

The strain on any part D, occasioned by a load uniformly 12.

formly distributed over the whole beam, is one-half of the strain that is produced when the same load is laid on

at D; and

The firain on the middle point C, occasioned by a load uniformly distributed over the whole beam, is the fame which half that load would produce if laid on

7. A beam supported at both ends on two props B and C (fig. 14.), will carry twice as much when the ends beyond the props are kept from riling, as it will

carry when it rests loosely on the props.

8. Lafly, the transverse strain on any section, occafioned by a force applied obliquely, is diminished in the proportion of the fine of the angle which the direction of the force makes with the beam. Thus, if it be inchined to it in an angle of thirty degrees, the strain is one half of the firain occasioned by the same force acting perpendicularly.

On the other hand, the RELATIVE STRENGTH of a beam, or its power in any particular fection to refelt any transverse strain, is proportional to the absolute cohelion of the fection directly, to the distance of its centre of effort from the axis of fracture directly, and to the distance from the strained point inversely.

Thus in a rectangular fection of the beam, of which b is the breadth, d the depth (that is, the dimension in the direction of the straining force), measured in inches, and f the number of pounds which one square inch will just support without being torn asunder, we must have $f \times b \times d^2$, proportional to $w \times CB$ (fig. 15.) Or, $f \times b \times d^2$, multiplied by some number m, depending on the nature of the timber, must be equal to w x CB. Or, in the case of the section C of fig. 16. that is

strained by the force w applied at D, we must have $m \times fb d^2 = w \times \frac{AC \times DB}{AB}$. Thus if the beam is of found oak, m is very nearly = 1/6 (fee STRENGTH of Materials, n° 116, Encycl.) Therefore we have $\frac{f b d^2}{9}$ = $w \times \frac{AC \times CB}{AB}$.

Hence we can tell the precise force w which any section C can just refilt when that force is applied in any way whatever. For the above mentioned formula gives $w = \frac{f b d^2}{9 \text{ CB}}$, for the case represented by fig. 15. -But the case represented in fig. 16. having the straining force applied at D, gives the strain at C = w = f $\times b d^2 \times AB$ 9ACXCB

Example. Let an oak beam, four inches square, rest freely on the props A and B, feven feet apart, or 8. inches. What weight will it just support at its middle point C, on the supposition that a square inch rod will just carry 16,000 pounds, pulling it asunder?

The formula becomes $w = \frac{16070 \times 4 \times 16 \times 84}{9 \times 42 \times 42}$, or $w = \frac{86016000}{15876}$, = 5418 pounds. This is very near what was employed in Buffon's experiment, which was 5312.

Had the straining force acted on a point D, half way between C and B, the force sufficient to break the beam

at C would be = $\frac{16000 \times 4 \times 16 \times 84}{9 \times 42 \times 21} = 10836$ lbs.

Had the beam been found red fir, we must have taken f = 10,000 nearly, and m nearly 8; for although fir be less cohesive than oak in the proportion of 5 to 8 nearly, it is less compressible, and its axis of fracture is therefore nearer to the concave side.

HAVING confidered at sufficient length the strains of joints of different kinds which arise from the form of the parts of a frame of carpentry, and the direction of the external forces which act on it, whether confidered as impelling or as supporting its different parts, we mult now proceed to confider the means by which this form is to be secured, and the connections by which those strains are excited and communicated.

The joinings practifed in carpentry are almost infinitely various, and each has advantages which make it preferable in some circumstances. Many varieties are employed merely to please the eye. We do not concern ourselves with these: Nor shall we consider those which are only employed in connecting small works, and can never appear on a great scale; yet even in some of these, the skill of the carpenter may be discovered by his choice; for in all cases, it is wife to make every, even the smallest, part of his work as strong as the materials will admit. He will be particularly attentive to the changes which will necessarily happen by the shrinking of timber as it dries, and will confider what dimensions of his framings will be affected by this, and what will not; and will then dispose the pieces which are less effential to the strength of the whole, in such a manner that their tendency to shrink shall be in the same direction with the shrinking of the whole framing. If he do otherwise, the seams will widen, and parts will be split

asunder. He will dispose his boardings in such a manner as to contribute to the stiffness of the whole, avoiding at the fame time the giving them positions which will produce lateral strains on truss beams which bear great pressures; recollecting, that although a fingle board has little force, yet many united have a great deal, and may frequently perform the office of very powerful

Our limits confine us to the joinings which are most effential for connecting the parts of a fingle piece of a frame when it cannot be formed of one beam, either for want of the necessary thickness or length; and the joints for connecting the different fides of a truffed

of building

up beams.

Much ingenuity and contrivance has been bestowed on the manner of building up a great beam of many thickneffes, and many fingular methods are practifed as great nostrums by different artists: but when we confider the manner in which the cohesion of the fibres performs its office, we will clearly see that the simplest are equally effectual with the most refined, and that they are less apt to lead us into false notions of the strength of the affeniblage.

Thus, were it required to build up a beam for a

Building up

Joggling

preferable

a girder or great lever or a girder, so that it may act nearly as a beam of the same size of one log-it may either be done by plain joggling, as in fig. 17. A, or by fcarfing, as in fig. 17. B or C. If it is to act as a lever, having the gudgeon on the lower fide at C, we believe that most artists will prefer the form B and C; at least to fearfing. this has been the case with nine-tenths of those to whom we have proposed the question. The best informed only hefitated; but the ordinary artists were all confident in its fuperiority; and we found their views of the matter very coincident. They confidered the upper piece as grasping the lower in its hooks; and several imagined that, by driving the one very tight on the other, the beam would be stronger than an entire log: but if we attend carefully to the internal procedure in the loaded lever, we shall find the upper one clearly the strongest. If they are formed of equal logs, the upper one is thicker than the other by the depth of the joggling or scarfing, which we suppose to be the same in both; consequently, if the cohesion of the sibres in the intervals is able to bring the uppermost filaments into full action, the form A is stronger than B, in the proportion of the greater distance of the upper filaments from the axis of the fracture: this may be greater than the difference of the thickness, if the wood is very compressible. If the gudgeon be in the middle, the effect, both of the joggles and the scarfings, is considerably diminished; and if it is on the upper side, the scarfings act in a very different way. In this fituation, if the loads on the arms are also applied to the upper fide, the joggled beam is still more superior to the scarfed one. This will be best understood by resolving it in imagination into a truffed frame. But when a gudgeon is thus put on that fide of the lever which grows convex by the strain, it is usual to connect it with the rest by a powerful strap, which embraces the beam, and causes the opposite point to become the resisting point. This greatly changes the internal actions of the filaments, and, in one measure, brings it into the same state as the first, with the gudgeon below. Were it possible to have the gudgeon on the upper side, and to bring the

whole into action without a strap, it would be the strongest of all; because, in general, the refistance to compression is greater than to extension. In every fituation the joggled beam has the advantage; and it is the easiest executed.

We may frequently gain a confiderable accession of strength by this building up of a beam; especially if the part which is stretched by the strain be of oak, and the other part be fir. Fir being fo much superior to oak as a pillar (if Musschenbroek's experiments may be confided in), and oak so much preserable as a tie, this construction seems to unite both advantages. But we shall fee much better methods of making powerful le.

vers, girders, &c. by truffing.

Observe, that the efficacy of both methods depends entirely on the difficulty of caufing the piece between the cross joints to slide along the timber to which it adheres. Therefore, if this be moderate, it is wrong to make the notches deep; for as foon as they are fo deep that their ends have a force sufficient to push the flice along the line of junction, nothing is gained by making them deeper; and this requires a

greater expenditure of timber.

Scarfings are frequently made oblique, as in fig. 18. but we imagine that this is a bad practice. It begins to yield at the point, where the wood is crippled and splintered off, or at least bruised out a little: as the pressure increases, this part, by squeezing broader, causes the folid parts rife to a little upwards, and gives them fome tendency, not only to push their antagonists along the base, but even to tear them up a little. For similar reasons, we disapprove of the favourite practice of many artists, to make the angles of their scarfings acute, as in fig. 19. This often causes the two pieces to tear each other up. The abutments should always be perpendicular to the directions of the pressures. Lest it should be forgotten in its proper place, we may extend this injunction also to the abutments of different pieces of a frame, and recommend it to the artist even to attend to the shrinking of the timbers by drying. When two timbers abut obliquely, the joint should be most full at the obtuse angle of the end; because, by drying, that angle grows more obtuse, and the beam would then be in danger of fplintering off at the acute angle.

It is evident, that the nicest work is indispensably We m necessary in building up a beam. The parts must abut not we on each other completely, and the smallest play or void too har takes away the whole efficacy. It is usual to give the butting joints a small taper to one side of the beam, so that they may require moderate blows of a maul to force them in, and the joints may be perfectly close when the external furfaces are even on each fide of the beam. But we must not exceed in the least degree; for a very taper wedge has great force; and if we have driven the pieces together by very heavy blows, we leave the whole in a state of violent strain, and the abutments are perhaps ready to splinter off by a small addition of presfure. This is like too fevere a proof for artillery; which, though not sufficient to burst the pieces, has weakened them to fuch a degree, that the strain of ordinary service is sufficient to complete the fracture. The workman is tempted to exceed in this, because it fmooths off and conceals all uneven feams; but he must be watched. It is not unufual to leave fome abutments open enough to admit a thin wedge reaching through

the beam. Nor is this a bad practice, if the wedge is of materials which is not compressed by the driving or the strain of service. Iron would be preserable for this purpose, and for the joggles, were it not that by its too great hardness it cripples the fibres of timber to some distance. In consequence of this, it often happens that, in beams which are subjected to desultory and sudden frains (as in the levers of reciprocating engines), the joggles or wedges widen the holes, and work themselves loofe : 'Therefore skilful engineers never admit them, and indeed as few bolts as possible, for the same reason : but when refifting a fleady or dead pull, they are not to improper, and are frequently used.

Beams are built up, not only to increase their dimenfons in the direction of the strain (which we have hitherto called their depth), but also to increase their breadth or the dimensions perpendicular to the strain. We sometimes double the breadth of a girder which is thought too weak for its load, and where we must not increase the thickness of the flooring. The mast of a great thip of war must be made bigger athwartship, as well as fore and aft. This is one of the nicest prouilding of blems of the art; and professional men are by no means agreed in their opinions about it. We do not prefume to decide; and shall content ourselves with exhibiting the different methods.

The most obvious and natural method is that shewn in fig. 20. It is plain that (independent of the connection of cross bolts, which are used in them all when the beams are square) the piece C cannot bend in the direction of the plane of the figure without bending the piece D along with it. This method is much used in the French navy; but it is undoubtedly imperfect. Hardly any two great trees are of equal quality, and fwell or shrink elike. If C shrinks more than D, the feather of C becomes loofe in the groove wrought in D to receive it; and when the beam bends, the parts can flide on each other like the plates of a coach spring; and if the bending is in the direction ef, there is nothing to hinder this sliding but the bolts, which foon work themselves loofe in the bolt-holes.

Fig. 21. exhibits another method. The two halves of the beam are tabled into each other in the same manner as in fig. 17. It is plain that this will not be affected by the unequal fwelling or shrinking, because this is infenfible in the direction of the fibres; but when bent in the direction ab, the beam is weaker than fig. 20. bent in the direction of. Each half of fig. 20. has, in every part of its length, a thickness greater than half the thickness of the beam. It is the contrary in the alternate portions of the halves of fig. 27. When one of them is bent in the direction AB, it is plain that it drags the other with it by means of the crofs butments of its tables, and there can be no longitudinal fliding. But unless the work is accurately executed, and each hollow completely filled up by the table of the other piece, there will be a lateral flide along the cross joints sufficient to compensate for the curvature; and this will hinder the one from comprelling or fretching the other in conformity to this curvature.

The imperfection of this method is fo obvious, that te imperiettion of this method is to obvious, that with the other, as is represented in fig. 22. where the beams are divided along the middle, and the tables in SUPPL. VOL. I. Part I.

each haif are alternate, and alternate also with the tables of the other half. Thus I, 3, 4, are prominent, and 5, 2, 6, are depressed. This construction evidently puts a stop to both slides, and obliges every part of both pieces to move together. ab and cd show sections of the built-up beam corresponding to AB and

No more is intended in this practice by any intelligent artift, than the caufing the two pieces to act together in all their parts, although the strains may be unequally distributed on them. Thus, in a built-up gir- . der, the binding joids are frequently mortifed into very different parts of the two fides. But many feem to aim at making the beam stronger than if it were of one piece; and this inconfiderate project has given rife to many whimfical modes of tabling and fearfing, which we need not regard.

The practice in the British dock yards is somewhat British different from any of these methods. The pieces are acthod; tabled as in fig. 22. but the tables are not thin parallelopipeds, but thin prisms. The two outward joints or visible seams are straight lines, and the table no 1. rifes gradually to its greatest thickness in the axis. In like manner, the hollow 5 for receiving the opposite table, finks gradually from the edge to its greatest depth in the axis. Fig. 23 represents a section of a round piece of timber built up in this way, where the full line EFGH is the fection corresponding to AB of fig. 22. and the dotted line EGFH is the Tection corresponding to CD.

This construction, by making the external feam straight, leaves no lodgment for water, and looks much fairer to the eye: but it appears to us that it does not give such firm hold when the matt is bent in the direction EH. The exterior parts are most stretched and most compressed by this bending; but there is hardly any abutment in the exterior parts of thefe tables. In the very axis, where the abutment is the firmest, there is little or no difference of extension and compression.

But this construction has an advantage, which we imagine much more than compensates for these imperfections, at least in the particular case of a round mast: it will draw together by hooping incomparably better than any of the others. If the cavity be made fomewhat too shallow for the prominence of the tables, and if this be done uniformly along the whole length, it will make a somewhat open seam; and this opening can be regulated with the utmost exactness from end to end by the plane. The heart of those vast trunks is very fentibly fofter than the exterior circles: Therefore, when the whole is hooped, and the hoops hard driven, and at confiderable intervals between each fpell -we are confident that all may be compressed till the feam disappears; and then the whole makes one piece, much stronger than if it were an original log of that fize, because the middle has become, by compression, as folid as the cruft, which was naturally firmer, and refitted farther compression. We verified this beyond a doubt, by hooping a built flick of a timber which has this inequality of firmuels in a remarkable degree, and it was nearly twice as strong as another of the same fize.

Our maltmakers are not without their fancies and whims; and the manner in which our mafts and yards

Tethod ted in the

Inother

fection.

are generally built up, is not near so simple as fig. 2.: but it consists of the same essential parts, acting in the very fame manner, and derives all its efficacy from the

principles which are here employed.

Attended liar advantages.

This construction is particularly suited to the situation and office of a ship's mast. It has no bolts; or, at least, none of any magnitude, or that make very important parts of its construction. The most violent strains perhaps that it is exposed to, is that of twisting, when the lower yards are close braced up by the force of many men acting by a long lever. This form refifts a twist with peculiar energy: it is therefore an excellent method for building up a great shaft for a mill. The way in which they are usually built up is by reducing a central log to a polygonal prism, and then filling it up to the intended fize by planting pieces of timber along its fides, either spiking them down, or cocking them into it by a feather, or joggling them by flips of hard wood funk into the central log and into the flips. N. B. Joggles of elm are sometimes used in the middle of the large tables of masts; and when funk into the firm wood near the furface, they must contribute much to the strength. But it is very necessary to employ wood not much harder than the pine; otherwise it will foon enlarge its bed, and become loofe; for the timber of these large trunks is very foft.

The most general reason for piecing a beam is to increase its length. This is frequently necessary, in order to procure tie-beams for very wide roofs. Two pieces must be scarfed together. - Numberless are the modes of doing this; and almost every master carpenter has his favourite nostrum. Some of them are very ingenious: But here, as in other cases, the most simple are commonly the strongest. We do not imagine that any, methods of the most ingenious, is equally strong with a tie consist-fearfing. ing of two pieces of the same scantling laid over each other for a certain length, and firmly bolted together. We acknowledge that this will appear an artlefs and clumfy tie-beam; but we only fay that it will be stronger than any that is more artificially made up of the same thickness of timber. This, we imagine, will appear fufficiently certain.

> The fimplest and most obvious scarsing (after the one now mentioned) is that represented in fig. 24. no 1. and 2. If confidered merely as two pieces of wood joined, it is plain that, as a tie, it has but half the strength of an entire piece, supposing that the bolts (which are the only connections) are fast in their holes. No 2 requires a bolt in the middle of the scarf to give it that strength; and, in every other part, is weaker on one fide or the other.

> But the bolts are very apt to bend by the violent: strain, and require to be strengthened by uniting their ends by iron plates; in which case it is no longer a wooden tie. The form of no 1. is better adapted to the office of a pillar than n° 2.; especially if its ends be formed in the manner shewn in the elevation no 3. By the fally given to the ends, the scarf resists an effort to bend it in that direction. Besides, the form of no 2. is unfuitable for a post; because the pieces, by sliding on each other by the pressure, are apt to splinter off the tongue which confines their extremity.

Fig. 25. and 26. exhibit the most approved form of a fearf, whether for a tie or for a post. The key re-

prefented in the middle is not effentially necessary; the two pieces might fimply meet square there. This form, without a key, needs no bolts (although they strengthen it greatly); but, if worked very true and close, and with fquare abutments, will hold together, and will refift bending in any direction. But the key is an ingenious and a very great improvement, and will force the parts together with perfect tightness. The same precaution must be observed that we mentioned on another occasion, not to produce a constant internal strain on the parts by overdriving the key. The form of fig. 25. is by far the best; because the triangle of 26. is much easier splintered off by the strain, or by the key, than the square wood of 25. It is far preferable for a post, for the reason given when speaking of fig. 24. no 1. and no 2. Both may be formed with a fally at the ends equal to the breadth of the key. In this shape fig. 25. is vastly well suited for joining the parts of the long corner posts of spires and other wooden towers, Fig. 25. n° 2. differs from no 1. only by having three keys. The principle and the longitudinal strength are the same. The long scarf of n 2. tightened by the three keys, enables it to refift a bending much better.

None of these scarfed tie-beams can have more than one third of the strength of an entire piece, unless with the affistance of iron plates; for if the key be mads thinner than one-third, it has less than one-third of the

fibres to pull by.

We are confident, therefore, that when the heads of the bolts are connected by plates, the simple form of fig. 24. no 1. is stronger than those more ingenious scarfings. It may be strengthened against lateral bending by a little tongue, or by a fally; but it cannot have both.

The strongest of all methods of piecing a tie beam would be to fet the parts end to end, and grafp them between other pieces on each fide, as in fig 27. This Fishing a is what the ship carpenter calls fishing a beam; and is a beam. frequent practice for occasional repairs. Mr Perronet used it for the tie beams or stretchers, by which he connected the opposite feet of a centre, which was yielding to its load, and had pushed aside one of the piers above four inches. Six of these not only withstood a strain of 1800 tons, but, by wedging behind them, he brought the feet of the truss 21/2 inches nearer. The fretchers were 14 inches by 11 of sound oak, and could have withflood three times that strain. Mr Perronet, fearing that the great length of the bolts employed to connect the beams of these stretchers would expose them to the risk of bending, scarfed the two side pieces into the middle piece. The fcarfing was of the triangular kind (Trait de Jupiter), and only an inch deep, each face being two feet long, and the bolt passed through close to the angle,

In piecing the pump rods, and other wooden ftretchers of great engines, no dependence is had on fearfing; and the engineer connects every thing by iron straps. We doubt the propriety of this, at least in cases where the bulk of the wooden connection is not inconvenient, These observations must suffice for the methods employed for connecting the parts of a beam; and we now proceed to confider what are more usually called the joints of a piece of carpentry.

Where the beams stand square with each other, and square the joints.

Various fearfing. plane of the frame, the common mortife and tenon is the most perfect junction. A pin is generally put through both, in order to keep the pieces united, in opposition to any force which tends to part them. Every carpenter knows how to bore the hole for this pin, fo that it shall draw the tenon tight into the mortife, and cause the shoulder to butt close, and make neat work; and he knows the risk of tearing out the bit of the tenon beyond the pin, if he draw it too much. We may just observe, that square holes and pins are much preferable to round ones for this purpose, bringing more of the wood into action, with less tendency to split it. The ship carpenters have an ingenious method of making long wooden bolts, which do not pass completely through, take a very fast hold, though not nicely fitted to their holes, which they must not be, left they should be crippled in driving. They call it foxtail wedging. They flick into the point of the bolt a very thin wedge of hard wood, fo as to project a proper distance: when this reaches the bottom of the hole by driving the bolt, it splits the end of it, and fqueezes it hard to the fide. This may be practifed with advantage in carpentry. If the ends of the mortise are widened inwards, and a thin wedge be put into the end of the tenon, it will have the fame effect, and make the joint equal to a dovetail. But this risks the splitting the piece beyond the shoulder of the tenon, which would be unlightly, This may be avoided as follows: Let the tenon i, fig. 28. have two very thin wedges a and c fluck in near its angles, projecting equally: at a very small distance within these, put in two shorter ones b, d, and more within these if necesfary. In driving this tenon, the wedges a and c will take first, and split off a thin slice, which will easily bend without breaking. The wedges b, d, will act next, and have a fimilar effect, and the others in fuccession. The thickness of all the wedges taken together must be equal to the enlargement of the mortile toward the bottom.

When the strain is transverse to the plane of the two beams, the principles laid down in no 85, 86. of the article STRENGTH of Materials, will direct the artist in placing his mortife. Thus the mortife in a girder for receiving the tenon of a binding joift of a floor should be as near the upper side as possible, because the girder becomes concave on that fide by the strain. But as this exposes the tenon of the binding-joilt to the risk of being torn off, we are obliged to mortise farther down. The form (fig. 29.) generally given to this joint is extremely judicious. The sloping part a b gives a very firm support to the additional bearing ed, without much weakening of the girder. This form should be copied in every cafe where the strain has a similar

The joint that most of all demands the careful attention of the artift, is that which connects the ends of mortife and beams, one of which pushes the other very obliquely, putting it into a flate of extension. The most familiar instance of this is the foot or a rafter pressing on the tie-beam, and thereby drawing it away from the other wall. When the direction is very oblique (in which case the extending strain is the greatest), it is difficult to give the foot of the rafter such a hold of the tie- shoulder lodges water; but the great reason seems to be

the strains are also square with the beams, and in the beam as to bring many of its sibres into the proper action. There would be little difficulty if we could allow the end of the tie-beam to project to a small distance beyond the foot of the rafter: but, indeed, the dimensions which are given to tie-beams, for other reafons, are always fufficient to give enough of abutment when judiciously employed. Unfortunately this joint is much exposed to failure by the effects of the weather. It is much expoled, and frequently perishes by rot, or becomes fo foft and friable that a very finall force is fufficient, either for pulling the filaments out of the tie beam, or for crushing them together. We are therefore obliged to fecure it with particular attention, and to avail ourselves of every circumstance of construction.

One is naturally disposed to give the rafter a deep hold by a long tenon; but it has been frequently obferve! in old roofs that fuch tenons break off. Frequently they are observed to tear up the wood that is above them, and push their way through the end of the tie-beam. This in all probability arises from the first fagging of the roof, by the compression of the rafters and of the head of the king post. The head of the rafter descends, the angle with the tie-beam is diminished by the rafter revolving round its step in the tie-beam. By this motion the heel or inner angle of the rafter becomes a fulcrum to a very long and powerful lever much The tenon is the other arm, very short, and loaded. being still fresh, it is therefore very powerful. It therefore forces up the wood that is above it, tearing it out from between the cheeks of the mortife, and then pushes it along. Carpenters have therefore given up long tenons, and give to the toe of the tenon a shape which abuts firmly, in the direction of the thrust, on the solid bottom of the mortife, which is well supported on the under fide by the wall plate. This form has the farther advantage of having no tendency to tear up the end of the mortise. This form is represented in fig. 30. The tenon has a fmall portion a b cut perpendicular to the furface of the tie-beam, and the rest bc is perpendicular to the rafter.

But if the tenon is not fufficiently strong (and it is not fo firong as the rater, which is thought not to be stronger than is necessary), it will be crushed, and then the rafter will shade out along the surface of the beam. It is therefore necessary to call in the assistance of the whole rafter. It is in this distribution of the strain among the various abutting parts that the varieties of joints and their merits chiefly confifts. It would be endless to describe every nostrum, and we shall only mention a few that are most generally approved of.

The aim in fig. 31 is to make the abutments exact- Most aply perpendicular to the thrusts. It does this very pre-proved cifely; and the share which the tenon and the shoulder forms, have of the whole may be what we please, by the portion of the beam that we notch down. If the wall plate lie duly before the heel of the rafter, there is no risk of ftraining the tie across or breaking it, because the thrust is made direct to that point where the beam is supported. The action is the same as against the joggle on the head or foot of a king post. We have no doubt but that this is a very effectual joint. It is not, however, much practifed. It is faid that the floping feam at the

Oblique tenon.

Foxtail

wedging.

a fecret notion that it weakens the tie beam. If we confider the direction in which it acts as a tie, we must acknowledge that this form takes the best method for

bringing the whole of it into action.

Fig. 32. exhibits a form that is more general, but certainly worle. What part of the thrust that is not borne by the tenon acts obliquely on the joint of the shoulder, and gives the whole a tendency to rife up and Dide outward.

The shoulder joint is sometimes formed like the dotted line abcdefg of fig. 32. This is much more agreeable to the true principle, and would be a very perfect method, were it not that the intervals bd and df are so short that the little wooden triangles bed, def, will be easily pushed off their bases bd, df.

Fig. 33. feems to have the most general approbation. It is the joint recommended by Price (page 7.), and copied into all books of carpentry as the true joint for a rafter foot. The visible shoulder-joint is slush with the upper furface of the tie beam 'The angle of the tenon at the tie nearly bifects the obtufe angle formed by the rafter and the beam, and is therefore somewhat oblique to the thrust. The inner shoulder ac is nearly perpendicular to bd. The lower angle of the tenon is cut off horizontally as at ed. Fig. 34. is a section of the beam and rafter foot, shewing the different shoulders.

We do not perceive the peculiar merit of this joint. The effect of the three oblique abutments ab, ac, ed, is undoubtedly to make the whole bear on the outer end of the mortise, and there is no other part of the tiebeam that makes immediate relistance. Its only advantage over a tenon extending in the direction of the thrust is, that it will not tear up the wood above it. Had the inner shoulder had the form eci, having its face ic perpendicular, it would certainly have acted more powerfully in stretching many filaments of the tiebeam, and would have had much less tendency to force out the end of the mortife. The little bit çi would have prevented the sliding upwards along ec. At any rate, the joint a b being flush with the beam, prevents any sensible abutment on the shoulder ac.

Fig. 33. No 2. is a fimpler, and in our opinion a preferable, joint. We observe it practised by the most eminent carpenters for all oblique thrusts; but it furely employs less of the cohesion of the tie beam than might be used without weakening it, at least when it is supported on the other fide by the wall plate.

Fig. 33. No 3. is also much practifed by the first car-

Fig. 25. is proposed by Mr Nicholson (page 65.) as preferable to fig. 33. no 3 because the abutment of the inner part is better supported. This is certainly the ease; but it supposes the whole rafter to go to the bottom of the focket, and the beam to be thicker than the rafter. Some may think that this will weaken the beam too much, when it is no broader than the rafter is thick; in which case they think that it requires a deeper socket than Nicholson has given it. Perhaps the advantages of Nicholson's construction may be had by a joint like fig. 35. n° 2.

Circum-Whatever is the form of these butting joints, great care should be taken that all parts bear alike, and the flances to be attended artist will attend to the magnitude of the different furfaces. In the general compression, the greater surfaces

will be less compressed, and the smaller will therefore change most. When all has settled, every part should he equally close. Because great logs are moved with difficulty, it is very troublesome to try the joint frequently to fee how the parts fit; therefore we must expect less accuracy in the interior parts. This should make us prefer those joints whose efficacy depends chief-

ly on the vifible joint.

It appears from all that we have faid on this subject, that a very small part of the cohesion of the tie-beam is fufficient for withstanding the horizontal thrust of a roof, even though very low pitched. If therefore no other use is made of the tie-beam, one much slenderer may be used, and blocks may be firmly fixed to the ends, on which the rafters might abut, as they do on the joggles on the head and foot of a king post. Although a tie-beam has commonly floors or ceilings to carry, and fometimes the workshops and store rooms of a theatre, and therefore requires a great fcantling, yet there frequently occur in machines and engines very oblique stretchers, which have no other office, and are generally made of dimensions quite inadequate to their situation, often containing ten times the neceffary quantity of timber. It is therefore of importance to afcertain the most perfect manner of executing such a joint. We have directed the attention to the principles that are really concerned in the effect. In all hazardous cases, the carpenter calls in the affishance of iron straps; and they are frequently necessary, even in roofs, notwithstanding this superabundant strength of the tie-beam. But this is generally owing to bad construction of the wooden joint, or to the failure of it by time. Straps will be considered in their place.

There needs but little to be faid of the joints at a joggle worked out of folid timber; they are not near fo difficult as the last. When the fize of a log will allow the joggle to receive the whole breadth of the abutting brace, it ought certainly to be made with a square shoulder; or, which is still better, an arch of a circle, having the other end of the brace for its centre. Indeed this in general will not fenfibly differ from a straight line perpendicular to the brace. By this circular form, the fettling of the roof makes no change in the abutment; but when there is not sufficient stuff for this, we must avoid bevel joints at the shoulders. because theie always tend to make the brace slide off. The brace in fig 36. must not be joined as at a, but as at b, or some equivalent manner. Observe the joints at the head of the main posts of Drury Lane theatre, fig. D.

When the very oblique action of one fide of a frame Butting of carpentry does not extend but compress the piece on jointes which it abuts (as in fig. 11.), there is no difficulty in the joint. Indeed a joining is unnecessary, and it is enough that the pieces abut on each other; and we have only to take care that the mutual preffure be equally borne by all the parts, and that it do not produce lateral pressures, which may cause one of the pieces to side on the butting joint. A very slight mortise and tenon is sufficient at the joggle of a king post with a rafter or thraining beam. It is best, in general, to make the butting plain, bisecting the angle formed by the fides, or else perpendicular to one of the pieces. In fig. 36. n° 2. where the straining beam a b cannot slip away from the pressure, the joint a is preserable to b, or

indeed to any uneven joint, which never fails to produce very unequal preffures on the different parts, by which some are crippled, others are splintered off, &c.

When it is necessary to employ iron straps for strengthg ening a joint, a considerable attention is necessary, that we may place them properly. The first thing to be determined is the direction of the strain. This is learned by the observations in the beginning of this article. We must then resolve this strain into a strain parallel to each piece, and another perpendicular to it. Then the strap which is to be made fast to any of the pieces must be so fixed, that it shall refist in the direction parallel to the piece. Frequently this cannot be done; but we must come as near to it as we can. In such cases we must suppose that the affemblage yields a little to the preffures which act on it. We must examine what change of shape a small yielding will produce. We must now fee how this will affect the iron strap which we have already supposed attached to the joint in some manner that we thought suitable. This settling will perhaps draw the pieces away from it, leaving it loofe and unferviceable (this frequently happens to the plates which are put to secure the obtuse angles of butting timbers, when their bolts are at some distance from the angles, especially when these plates are laid on the inside of the angles); or it may cause it to compress the pieces harder than before; in which case it is answering our intention. But it may be producing cross strains, which may break them; or it may be crippling them. We can hardly give any general rules; but the reader will do well to read what is written in no 36. and 41. of the article Roof, Encycl. In no 36. he will fee the nature of the strap or stirrup, by which the king post carries the tie beam. The firap that we observe most generally illplaced is that which connects the foot of the rafter with the beam. It only binds down the rafter, but does not act against its horizontal thrust. It should be placed farther back on the beam, with a bolt through it, which will allow it to turn round. It should embrace the rafter almost horizontally near the foot, and should be notched square with the back of the rafter. Such a construction is represented in fig. 37. By moving round the eye bolt, it follows the rafter, and cannot pinch and cripple it, which it always does in its ordinary form. We are of opinion that straps which have eye-bolts in the very angles, and allow all motion round them, are of all the most perfect. A branched strap, such as may at once bind the king post and the two braces which butt on its foot, will be more serviceable if it have a When a roof warps, those branched straps frequently break the tenons, by affording a fulcrum in one of their bolts. An attentive and judicious artist will consider how the beams will act on such occasions, and will avoid giving rife to these great thrains by levers -A skilful carpenter never employs many straps, considering them as auxiliaries foreign to his art, and subject to imperfections in workmanship which he cannot discern nor amend. We must refer the reader to Nicholson's CARPENCER AND JOINER'S ASSISTANT for a more particular account of the various forms of flirrups, ferewed rods, and other iron work for carrying tie-beams, &c.

As for those that are necessary for the turning joints of great engines constructed of timber, they make no part of the art of carpentry.

AFTER having attempted to give a fystematic view 42 of the principles of framing carpentry, we shall confediment of different clude, by giving some examples which will illustrate and pieces of confirm the foregoing principles.

Fig. 38. is the roof of the chapel of the Royal Hofpital at Greenwich, constructed by Mr S. Wyatt.

att: Roof of Greenwich Chapel.

AA, Is the tie-beam, 57 feet long, spanning

51 feet clear		-		14 by	7 1	2
CC, Queen polts	-		-	93	× 1	2

H, A cambered bear	n for t	he platfor	m	1	9	.7
B, An iron string, su	apport	ing the ti	e-beam	2	X	2

The truffes are 7 feet apart, and the whole is covered with lead, the boarding being supported by horizontal ledgers h, h, of 6 by 4 inches.

This is a beautiful roof, and contains less timber than most of its dimensions. The parts are all disposed with great judgment. Perhaps the iron rod is unnecessary; but it adds great stiffness to the whole.

The iron fraps at the rafter feet would have had more effect if not so oblique. Those at the head of the posts are very effective.

We may observe, however, that the joints between the straining beam and its braces are not of the best kind, and tend to bruise both the straining beam and the truss beam above it.

Fig. 39. the roof of St Paul's, Covent Garden, con St Paul's, tructed by Mr Wapfhot in 1796.

HH, Principal rafter (at bottom) -	10 × 8 1
gg, Studs supporting the rafter	8×8

This roof far excels the original one put up by Inigo Jones. One of its truffes contains 198 feet of timber. One of the old roof had 273, but had many inactive timbers, and others ill disposed (N. B. The figure which we gave of it in the article Roor, copied from Price, is very erroneous). The internal truss FCF is admirably contrived for supporting the exterior rafters, without any preflure on the far projecting ends of the tie-beam. The former roof had bent them greatly, so as to appear ungraceful.

We think that the camber (fix inches) of the tiebeam is rather hurtful; because by fettling, the beam lengthens; and this must be accompanied by a considerable finking of the roof. This will appear by calcula-

Fig. 40. the roof of Birmingham theatre, construct Birminged by Mr Geo. Saunders. The span is 80 feet clear, ham theatre and the trusses are 10 feet apart.

This roof is a fine specimen of British carpentry, and is one of the boldest and lightest roofs in Europe. The fraining fill Q gives a firm abutment to the principal braces, and the space between the posts is 192 feet wide, affording roomy workshops for the carpenters and other workmen connected with a theatre. The contrivance for taking double hold of the wall, which is very thin, is excellent. There is also added a beam (marked R), bolted down to the tie-beams. The intention of this was to prevent the total failure of fo bold a truffing, if any of the tie-beams should fail at the end by rot.

theatre.

A6 Drury Lane Akin to this roof is fig. 41. the roof of Drury Lane theatre, 80 feet 3 inches in the clear, and the truffes 15 feet apart, constructed by Mr Edward Grey Saunders.

	Struts	8 × 12
	G	12 X 12
-,	5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5	12 1.2

The main beams are truffed in the middle space with oak truffes 5 inches square. This was necessary for its width of 32 feet, occupied by the carpenters, painters, &c. The great space between the trusses afford good

store-rooms, dreffing rooms, &c.

It is probable that this roof has not its equal in the world for lightness, stiffness, and strength. The main truss is so judiciously framed, that each of them will safely bear a load of near 300 tons; fo it is not likely that they will ever be quarter loaded. The division of the whole into three parts makes the exterior roofings very light. The strains are admirably kept from the walls, and the walls are even firmly bound together by the roof. They also take off the dead weight from the main truss one-third.

Remarks.

The intelligent reader will perceive that all these roofs are on one principle, depending on a truss of three pieces and a straight tie-beam. This is indeed the great principle of a trufs, and is a step beyond the roof with two rafters and a king post. It admits of much greater variety of forms, and of greater extent. We may fee, that even the middle part may be carried to any space, and yet be flat at top; for the truss-beam may be supported in the middle by an inverted king post (of timber, not iron), carried by iron or wooden ties from its extremities: And the fame ties may carry

the horizontal tie-beam K; for till K be torn afunder, or M, M, and P be crippled, nothing can fail.

The roof of St Martin's church in the Fields is confirmeted on good principles, and every piece properly disposed. But although its span does not exceed 42 feet from column to column, it contains more timber in a truss than there is in one of Drury Lane theatre. The roof of the chapel at Greenwich, that of St Paul's, Co. vent Garden, that of Birmingham, and that of Drury Lane theatres, form a feries gradually more perfect. Such specimens afford excellent leffons to the artists. We therefore account them a useful present to the pub-

There is a very ingenious project offered to the pub-Project lic by Mr Nicholfon (Carpenter's Affittant, p. 68.) He Mr N proposes iron rods for king posts, queen posts, and all' other fituations where beams perform the office or ties. This is in profecution of the notions which we published in the article Roof of the Encycl. (fee no 36, 37.) He receives the feet of the braces and ftruts in a focket very well connected with the foot of his iron king polt; and he fecures the feet of his queen posts from being pushed inwards, by interposing a straining sill. He does not even mortise the foot of his principal rafter into the end of the tie-beam, but fets it in a focket like a shoe, at the end of an iron bar, which is bolted into the tie beam a good way back. All the parts are formed and disposed with the precision of a person thoroughly acquainted with the subject; and we have not the smallest doubt of the fuccess of the project, and the complete fecurity and durability of his roofs, and we expect to fee many of them executed. We abound in iron, but we must fend abroad for building timber. This is therefore a valuable project; at the fame time, however, let us not over-rate its value. Iron is but about 12 times ftronger than red fir, and is more than 12 times heavier; nor is it cheaper, weight for weight, or ftrength for strength.

Our illustrations and examples have been chiefly taken from roofs, because they are the most familiar instances of the difficult problems of the art. We could have wished for more room even on this subject. The construction of dome roots has been (we think) mistaken, and the difficulty is much lefs than is imagined. We mean in respect of strength; for we grant that the obliquity of the joints, and a general intricacy, increases the trouble of workmanship exceedingly. Another opportunity may perhaps occur for confidering this fubject. Wooden bridges form another class equally diffi- Wood cult and important; but our limits are already overpal- br dg fed, and will not admit them. The principle on which they should all be constructed, without exception, is that of a trufs, avoiding all lateral bearings on any of the timbers. In the application of this principle, we must farther remark, that the angles of our truss should be as acute as possible; therefore we should make it of as few and as long pieces as we can, taking care to prevent the bending of the truss beams by bridles, which embrace them, but without preffing them to either fide. When the truss confifts of many pieces, the angles are very obtuse; and the thrusts increase nearly in the duplicate proportion of the number of angles. The proper maxims will readily occur to the artist who considers with attention the specimens of centres or coombs, which we shall give in the article CENTRE.

With

With respect to the frames of carpentry which occur in engines and great machines, the varieties are such that it would require a volume to treat of them properly. The principles are already laid down; and if the reader be really interested in the study, he will engage in it with seriousness, and cannot fail of being instructed. We recommend to his confideration, as a specimen of what may be done in this way, the working beam of Hornblower's steam engine (see STEAM-Engine, nº 84. Encycl.) When the beam must act by chains hung from the upper end of arch heads, the framing there given seems very scientifically constructed; at the same time, we think that a strap of wrought iron, reaching the whole length of the upper bar (fee the figure), would be vaftly preferable to those partial plates which the engineer has put there, for the bolts will foon work

But when arches are not neceffary, the form employed by Mr Watt is vafily preferable, both for fimplicity and for strength. It consists of a simple beam AB (fig. 42.), having the gudgeon C on the upper side. The two piston rods are attached to wrought iron joints A and B. Two strong struts DC, EC rest on the upper side of the gudgeon, and carry an iron string ADEB, consisting of three pieces, connected with the struts by proper joints of wrought iron. A more minute description is not needed for a clear conception of the principle. No part of this is exposed to a cross strain; even the beam AB might be sawed through at the middle. The iron string is the only part which is

firetched; for AC, DC, EC, BC, are all in a flate of compression. We have made the angles equal, that all may be as great as possible, and the pressure on the struts and strings a minimum. Mr Watt makes them much lower, as AdeB, or A^{seB} . But this is for economy, because the strength is almost insuperable. It might be made with wooden strings; but the workmanship of the joints would more than compensate the cheapness of the materials.

WE offer this article to the public with deference, Conclusionand we hope for an indulgent reception of our essay on a subject which is in a manner new, and would require much study. We have bestowed our chief attention on the strength of the construction, because it is here that persons of the profession have the most scanty information. We beg them not to confider our observations as too refined, and that they will study them with care. One principle runs through the whole; and when that is clearly conceived and familiar to the mind, we venture to say that the practitioner will find it of easy application, and that he will improve every performance by a continual reference to it.

If this attempt to instruct our most valuable and much esteemed artists shall appear to meet with their approbation, it may encourage us to engage in the serious task of composing a system on the subject. But this is a great work, and will require much time and liberal contribution of knowledge from the eminent carpenters who do honour to this country by their works.

CAR

CARRE' (Lewis), was, in 1663, born in the province of Brie in France; and refufing to enter into the fervice of the church, for which his education was intended to fit him, he incurred the displeasure of his father. His resources being thus cut off, he was obliged to quit the university, and go out into the world without employment or the means of subfishence. In this exigency he was fomehow introduced to the celebrated Malebranche, and retained by him as an amanuenfis. Under this great mafter he studied mathematics and metaphyfics, and could hardly fail to become strongly attached to the latter science. After residing seven years with Malebranche, he resolved to enter upon some employment, which might procure him a less precarious. establishment than what could be enjoyed by the favour of any individual: and with that view he began at Paris a course of lectures in mathematics, metaphysics, and moral philosophy, to such young ladies and gentlemen as chose to put themselves under his tuition. we think of the master under whom he himself studied those sciences, we cannot wonder that he made geometry serve merely as an introduction to his beloved metaphysics; and indeed the order of his course deserves to be univerfally adopted. It is furely much better to accustom the youthful mind to steady apprehension and patient thinking in the fludy of the ancient geometry, before it proceed to sciences more abstract, than to hurry it at once, as is the practice in some universities, into all the mazes and intricacies of what is called the first philosophy.

But although M. Carré gave the preference to meta-

CAR

physics, he did not neglect mathematics; and while he taught both, he took care to make himself acquainted with all the new discoveries in the latter. This was all that his constant attendance on his pupils would allow him to do till the year 1697, when M. Varignon, fo remarkable for his extreme scrupulousness in the choice of his eleves, took M. Carré to him in that station: Soon after, viz. in the year 1700, our author, thinking himself bound to do something that might render him worthy of that title, published the first complete work on the integral calculus, under the title of "A Method of Measuring Surfaces and Solids, and finding their Centres of Gravity, Percussion, and Oscillation." afterwards discovered some errors in the work, and was candid enough to own and correct them in a subsequent edition.

In a little time M. Carré became affociate, and at length one of the pensioners of the Academy. And as this was a sufficient establishment for one who knew so well how to keep his desires within just bounds, he gave himself up entirely to study; and as he enjoyed the appointment of mechanician, he applied himself more particularly to mechanics. He took also a survey of every branch relating to music; such as the doctrine of sounds, and the description of musical instruments; though he despited the practice of music as a mere sensual pleasure. Some sketches of his ingenuity and industry in this way may be seen in the Memoirs of the French Academy of Sciences. M. Carré also composed some treatises on other branches of natural philosophy, and some on mathematical subjects; all which he bequeath

Carré.

Carré Cafemate.

ed to that illustrious body, though it does not appear that any of them have yet been published. It is not unlikely that he was hindered from putting the last hand to them by a train of disorders proceeding from a bad digestion, which, after haraffing him during the space of five or fix years, at length brought him to the grave in

1711, at 48 years of age.

Though he possessed a considerable degree of science and much ingenuity, like many other eminent men he had neelected in his youth to study the language of his native country. In consequence of this, one of the earliest of his semale pupils, perceiving that his language was the reverse of elegant, told him pleasantly, that as an acknowledgment for the trouble which he had taken to teach her philosophy, she would in return teach him French; and he ever afterwards said, that from her lessons he had reaped great advantage. To this circumstance probably it was owing that he thought more highly of the genius of women than that of men.

The following is a chronological lift of his memoirs

printed in the volumes of the Academy.

1. The rectification of curve lines by tangents, 1701. 2. Solution of a problem proposed to geometricians, &c. 1701. 3. Reflections on the table of equations, 1701. 4. On the cause of the refraction of light, 1702. Why the tides are always augmenting from Breft to St Malo, and diminishing along the coasts of Normandy, 1702. 6. The number and the names of musical instruments, 1702. 7. On the vinegar which causes small Aones to roll upon an inclined plane, 1703. 8. On the rectification, &c. of the caustics by reslection, 1703. 9. Method for the rectification of curves, 1704. 10. Obfervations on the production of found, 1704. 11. On a curve formed from a circle, 1705. 12. On the refraction of musket balls in water, and on the refistance of that fluid, 1705. 13. Experiments on capillary tubes, 1705. 14. On the proportion of pipes to have a determinate quantity of water, 1705. 15. On the laws of motion, 1706. 16. On the properties of pendulums, with some new properties of the parabola, 1707. 17. On the proportion of cylinders, that their founds may form the musical cords, 1709. 18. On the elasticity of the air, 1710. 19. On catoptrics, 1710. 20. On the Monochord: in the Machines, tom. 1. with some other pieces, not mathematical.

CASCABEL, the knob or button of metal behind the breech of a cannon, as a kind of handle by which to elevate and direct the piece; to which some add the

fillet and ogees as far as the bafe-ring.

CASEMATE, or CAZEMATE, in fortification, a kind of vault or arch of ftone work, in that part of the flank of a baffion next the curtain; ferving as a battery to defend the face of the opposite bastion, and the moat or ditch.

It is now feldom used, because the batteries of the enemy are apt to bury the artillery of the casemate in the ruins of the vault; beside, the great smoke made by the dischare of the cannon renders it intolerable to the men. So that, instead of the ancient covered casemates, later engineers have contrived open ones, only guarded by a parapet, &c.

CASEMATE is also used for a well with several subterraneous branches, dug in the passage of the bassion, till the miner is heard at work, and air given to the mine. CASSINI (James), a celebrated French aftronome, was born at Paris February 18, 1677, being the younger fon of Johannes Dominicus Casini, of whom some account has been given in the Encyclopadia.

After his first studies in his father's house, in which it is not to be supposed that mathematics and astronomy would be neglected, he was fent to fludy philosophy at the Mazarine college, where the celebrated Varignon was then professor of mathematics. From the affistance of this eminent man young Cassini profited so well, that at is years of age he supported a mathematical thesis with great honour. At the age of 17 he was admitted a member of the Academy of Sciences; and the same year he accompanied his father in a journey to Italy, where he affifted him in the verification of the meridian at Bo. logna and other measurements. On his return he performed familiar operations in a journey into Holland, where he discovered some errors in the measure of the earth by Snell, the refult of which was communicated to the Academy in 1702. He made also a visit to England in 1696, where he was made a member of the Royal Society. In 1712 he succeeded his father as aftronomer royal at the observatory of Paris. In 1717 he gave to the Academy his refearches on the distance of the fixed ftars; in which he shewed that the whole annual orbit, of near 200 millions of miles diameter, is but as a point in comparison of that distance. The same year he communicated also his discoveries concerning the inclination of the orbits of the fatellites in general, and especially of those of Saturn's fatellites and ring. In 1725 he undertook to determine the cause of the moon's libration, by which she shews sometimes a little towards one fide, and fometimes a little on the other, of that half which is commonly behind or hid from our view.

In 1732 an important question in astronomy exercised the ingenuity of our author. His father had determined, by his observations, that the planet Venus revolved about her axis in the space of 23 hours; and M. Bianchini had published a work in 1729, in which he settled the period of the same revolution at 24 days 8 hours. From an examination of Bianchini's observations which were upon the fpots in Venus, he discovered that he had intermitted his observations for the space of three hours, from which cause he had probably mistaken new fpots for the old ones, and so had been led into the miflake. The probability is, that both had fallen into fome mistake, or that they had proceeded on very different principles; for otherwise such different results are wholly unaccountable. Dr Herfchel feems fatisfied that the period of the revolution is lefs than Bianchini has made; but he does not fay what it is, or that it is not much greater than it was supposed by Cassini. Our author, after he had convicted Bianchini, as he thought, of error, determined the nature and quantity of the acceleration of the motion of Jupiter at half a fecond per year, and of that of the retardation of Saturn at two minutes per year; that these quantities would go on increasing for 2000 years, and then would decrease again. In 1,740 he published his Attronomical ables, and his Elements of Attronomy; very extensive and se-

Although afronomy was the principal object of our author's confideration, he did not confine himfelf ablolutely to that branch, but made occasional excursions

into

Experiments on Electricity, or the Light produced by Bodies by Friction; Experiments on the Recoil of Firearms; Refearches on the Rife of the Mercury in the Barometer at different Heights above the Level of the Sea; Reflections on the perfecting of Burning-glaffes; and other Memoirs.

The French Academy had properly judged, that one of its most important objects was the measurement of the earth. In 1669 Picard measured a little more than a degree of latitude to the north of Paris; but as that extent appeared too small from which to conclude the whole circumference with fufficient accuracy, it was refolved to continue that measurement on the meridian of Paris to the north and the fouth, through the whole extent of the country. Accordingly, in 1683, the late M. de la Hire continued that on the north fide of Paris, and the older Caffini that on the fouth fide. The latter was affifted in 1700 in the continuation of this operation by his fon our author. The fame work was farther continued by the fame academicians; and, finally, the part left unfinished by De la Hire in the north was finished in 1718 by our author, with the late Maraldi,

and De la Hire the younger. These operations produced a considerable degree of precition. It appeared also, from this measured extent of fix degrees, that the degrees were of different lengths in different parts of the meridian; and in such fort that our author concluded, in the volume published for 1718, that they decreased more and more towards the pole, and that therefore the figure of the earth was that of an oblong spheroid, or having its axis longer than the equatorial diameter. He also measured the perpendicular to the same meridian, and compared the measured distance with the differences of longitude as before determined by the eclipses of Jupiter's fatellites: whence he concluded that the length of the degrees of longitude was smaller than it would be on a sphere, and that therefore again the figure of the earth was an oblong fpheroid, contrary to the determination of Newton by the theory of gravity. Though Newton was of all men the most averse from controversy, the other mathematicians in Britain did not tamely fubmit to conclusions in direct opposition to the fundamental doctrine of a philosopher of whose talents the nation was justly proud. The consequence was, that the French government sent two different fets of measurers, the one to measure a degree at the equator, the other at the polar circle; and the comparison of the whole determined the figure to be an

oblate spheroid, contrary to Cassini's determination After a long and laborious life, James Cassini died in April 1756, in consequence of a fall, and was succeeded in the Academy and Observatory by the subject of the following article. He published, A Treatise on the Magnitude and Figure of the Earth; as also, The Elements or Theory of the Planets, with Tables; beside an infinite number of papers in the Memoirs of the

Academy, from the year 1699 to 1755. Cassini de Thury (Cefar François), a celebrated French astronomer, director of the observatory, pensioner astronomer, and nember of most of the learned societies of Europe, was born at Paris June 17. 1714, being the fecond fon of James Cassini, the subject of the preceding memoir, whose occupations and talents he inherited and supported with great honour. He received his first lessons tution, which carried him through the many laborious

SUPPL. VOL. I. Part I.

into other fields. We owe also to him, for example, in astronomy and mathematics from MM. Maraldi and Cassini, Camus; and made such a rapid progress, that when he was not more than ten years of age he calculated the phases of a total eclipse of the sun. At the age of eighteen he accompanied his father in his two journeys undertaken for drawing the perpendicular to the obfervatory meridian from Strasbourg to Breft. From that time a general chart of France was devised; for which purpose it was necessary to traverse the country by feveral lines parallel and perpendicular to the meridian of Paris, and our author was charged with the conduct of this bufiness; in which he was so scrupulous as to measure again what had been measured by his father. This great work was published in 1740, with a chart shewing the new meridian of Paris, by two different series of triangles, passing along the sea coasts to Bayonne, traverfing the frontiers of Spain to the Mediterranean and Antibes, and thence along the eathern limits of France to Dunkirk, with parallel and perpendicular lines described at the distance of 6000 toiles from one another, from fide to fide of the country.

A tour which, in 1741, our author made in Flanders, in the train of the king, gave rife, at his majesty's instance, to the chart of France; relative to which Caffini published different works, as well as a great number of the sheets of the chart itself. In 1761 he undertook an expedition into Germany, for the purpose of continuing to Vienna the perpendicular of the Paris meridian; to unite the triangles of the chart of France with the points taken in Germany; to prepare the means of extending into that country the same plan as in France; and thus to establish succeffively for all Europe a most useful uniformity.-Our author was at Vienna the 6th of June 1761, the day of the transit of the planet Venus over the sun, of which he observed as much as the state of the weather would permit him to do, and published the account of

it in his Voyage en Allemagne.

Finally, M. Caffini, always meditating the perfection of his grand defign, profited of the peace of 1783 to piopose the joining of certain points taken upon the English coast with those which had been determined on the coast of France, and thus to connect the general chart of the latter with that of the British isles, like as he had before united it with those of Flanders and Germany. The propofal was favourably received by the English government, and presently carried into effect under the direction of the Royal Society, the execution being committed to the late General Roy. See the life of that general in this Supplement.

Between the years 1735 and 1770, M. Caffini published, in the volumes of Memoirs of the French Academy, a prodigious number of pieces, confifting chiefly of astronomical observations and questions; among which are observable, refearches concerning the parallax of the fun, the moon, Mars, and Venus; on astronomical refractions, and the effect caufed in their quantity and laws by the weather; numerous observations on the obliquity of the ecliptic, and on the law of its variations. In short, he cultivated astronomy for fifty years, the most important for that science that ever elapsed for the magnitude and variety of objects, in which he commonly sustained a principal share.

M. Cassini was of a very strong and vigorous consti-

Castrame- operations in geography and astronomy which he conducted. An habitual retention of urine, however, ren-Catalogue dered the last twelve years of his life very painful and of Books. distressing, till it was at length terminated by the smallpox the 4th of September 1784, in the 71st year of his age. He was succeeded in the academy, and as director of the observatory, by his only fon John-Dominic Cassini, the fourth in order of direct descent who has filled that honourable station.

CATACAUSTICS, or CATACAUSTIC CURVES, in the higher geometry, are the species of caustic curves tormed by reflection.

CATACOUSTICS, or CATAPHONICS, is the science of reflected founds; or that part of acoustics which treats

of the properties of echoes.

CATALOGUES of Books, is a subject of which a very curious history has been given to the world by Professor Beckmann. In the Encyclopædia mention has been made of fome of the most valuable catalogues, their defects pointed out, and rules given for making them more perfect; but nothing has there been faid of their origin, or of the uses which might be made of the

oldest catalogues.

According to the Professor, George Willer, whom fome improperly call Viller, and others Walter, a bookfeller at Augsburg, who kept a very large shop, and frequented the Franckfort fairs, first fell upon the plan of causing to be printed, before every fair, a catalogue of all the new books, in which the fize and printers names were marked. Le Mire, better known under the name of Miræus, fays, that catalogues were first printed in the year 1554; but Labbe (a), Reimann (B), and Heumann (c), who took their information from Le Mire, make the year erroneously to be 1564. Willer's eatalogues were printed till the year 1592 by Nicol. Baffæus, printer at Franckfort. Other booksellers, however, must have foon published catalogues of the like kind, though that of Willer continued a long time to be the principal.

In all thefe catalogues which are in quarto and not paged, the following order is observed. The Latin books occupy the first place, beginning with the Protestant theological works, perhaps because Willer was a Lutheran; then come the Catholic; and after thefe, books of jurifprudence, medicine, philosophy, poetry, and music. The second place is assigned to German

books, which are arranged in the fame manner.

The bookfellers of Leipfic foon perceived the advantage of catalogues, and began not only to reprint those of Franckfort, but also to enlarge them with many books which had not been brought to the fairs in that city. Our author had for some time in his custody, Gatalogus universalis pro nundinis Francosurtensibus vernalibus, de anno 1600; or, A catalogue of all the books on fale in Book street, Franckfort, and also of the books published at Leipsic, which have not been brought to

Franckfort, with the permission of his highness the elec- Catalogu tor of Saxony, to those new works which have appeared of Books at Leipfic. Printed at Leipfic by Abraham Lamberg, and to be had at his shop. On the September catalogue of the same year, it is said that it is printed from the Franckfort copy with additions. He found an Imperial privilege for the first time on the Franckfort September catalogue of 1616: Cum gratia et privilegio speciali s. caef. maj. Prostat apud J. Krugerum Augustanum.

Reimmann fays, that after Willer's death the catalogue was published by the Leipsic bookseller Henning Groffe, and by his fon and grandfon. The council of Franckfort caused several regulations to be issued refreeting catalogues; an account of which may be feen in D. Oth's Treatife on the Imperial Fairs at Franck. fort. After the business of book-telling was drawn from Franckfort to Leipfic, occasioned principally by the reftrictions to which it was subjected at the former by the censors, no more catalogues were printed there; and the shops in Book-street were gradually converted

into taverns (D).

"In the 16th century there were few libraries; and there, which did not contain may books, were in monasteries, and consisted principally of theological, philofophical, and historical works, with a few, however, on jurisprudence and medicine; while those which treated of agriculture, manufactures, and trade, were thought unworthy of the notice of the learned, or of being preferved in large collections. 'The number of these works was, nevertheless, far from being inconfiderable; and at any rate, many of them would have been of great use, as they would have ferved to illustrate the instructive history of the arts. Catalogues which might have given occasion to inquiries after books, that may be still somewhere preserved, have suffered the fate of tomb stones, which, being wafted and crumble 1 to pieces by the deftroying hand of time, become no longer legible. A complete series of them perhaps is nowhere to be found, at least I do not remember (fays the Professor) to have ever feen one in any library."

This loss, however, he thinks, might be in some meafure fupplied by the catalogues of Clefs and Draudius; who, by the defire of fome bookfellers, collected together all the catalogues which had been published at the different fairs in different years. The work of Cleis has the following title: Unius fæculi ejusque virorum litteratorum monumentis tum florentissimi, tum fertilissimi, ab anno 1500 ad 1602 nundinarum autumnalium inclusive, elenchus consummatissimus-desuntus partim ex singularum nundinarum catalogis, partim ex bibliothecis. Auctore Joanne Clessio, Wineccensi, Hannoio, philotopho ac medico.-By the editor's preface, it appears that the first edition was published in 1592. The order is almost the same

as that observed by Willer in his catalogues.

The work of Draudius, which was printed in several quarto volumes for the first time in 161, and afterwards in 1625, is far larger, more complete, and more methodical. Our author, however, contesses, that he

⁽c) Conspectus Reip. Litter. c. vi. § 2. p. 316. (D) Joh. Adolph. Stock, Frankfurter Chronik, p. 77.

gue never saw a perfect copy of either edition. This catastare, logue confifts of three parts; of which the first has the title of Bibliotheca classica, sive Catalogus officinalis, in quo singuli singularum facultatum ac professionum libri, qui in quavis fere lingua extant-recenfentur; ufque ad annum 1624 inclusive. Auctore M. Georgio Draudio .-It contains Latin works on theology, jurisprudence, medicine, history, geography, and politics. The copy in the library of the university of Gottingen ends at page 1304, which has, however, a catch-word, that feems to indicate a deficiency .- The fecond part is entitled, Bibliotheca classica sive Catalogus officinalis, in quo philosophici artiumque adeo humaniorum, poetici etiam et musici libri usque ad annum 1624 continentur. This part, containing Latin books also, begins at page 1298, and ends with page 1654, which is followed by an index of all the authors mentioned .- A fmaller volume, of 302 pages without au index, has for title, Bibliotheca exotica, five Catalogus officina is librorum peregrinis linguis ufualibus scriptorum. And a third part, forming 759 pages, besides an index of the authors, is called, Bibliotheca librorum Germanicorum classica; that is, A catalogue of all the books printed in the German language till the year 1625.

We have reason to believe that there are other editions of this catalogue than those mentioned by Profesfor Beckmann; and it might become fome prince or great man, for it is not a work for a bookfeller, to compare all the editions together, and publish a new one more corres than any that is at present extant indeed would be an expensive and not an easy task; for our author observes, that all the oldest catalogues had the same faults as those of later date, and that these faults have been copied by Draudius. Many books are mentioned which were never printed, and many titles, names, and dates, are given incorrectly; but Draudius nevertheless is well worth the attention of any one who may be inclined to employ his time and ingenuity on the history of literature; and his work certainly was of use to Haller when he composed his Bibliotheca.

CATATOGUES of the Stars, have usually been disposed, either as collected into certain figures called confiellations, or according to their right ascentions, that is, the order of their passing over the meridian.

Of the principal catalogues, according to the first of these forms, an account has been given in the Encyclopadia. The first catalogue, we believe, that was printed in the new or fecond form, according to the order of the right afcentions, is that of De la Caille, given in his Ephemerides for the ten years between 1755 and 1765, and printed in 1755. It contains the right afcentions and declinations of 307 stars, adapted to the beginning of the year 1750. In 1757 De la Caille published his Astronomia Fundamenta, containing a catalogue of the right afcentions and declinations of 398 flars, likewife adapted to the beginning of 1750. And in 1763, the year after his death, was published the Calum Australe Stelliferum of the same author; containing a catalogue of the places of 1942 flars, all fituated to the fouthward of the tropic of Capricorn, and observed by him while he was at the Cape of Good Hope in 1751 and 1752; their places being also adapted to the beginning of 1750. In the same year was published his Ephemerides for the ten years between 1765 and 1775; in the introduction to which are given the places of 515 20-

diacal stars, all deduced from the observations of the Catalogus same author; the places adapted to the beginning of of the Stars. the year 1765.

In the Nautical Almanac for 1773, is given a catalogue of 387 stars, in right afcension, declination, longitude, and latitude, derived from the observations of the late celebrated Dr Bradley, and adjusted to the beginning of the year 1760. This small catalogue, and the results of about 1200 observations of the moon, are all that the public have yet seen of the multiplied labours of this most accurate and indefatigable observer, although he has now (1798) been dead upwards of 36 years.

In 1775 was publified a thin volume, intitled. Opera Inedita, containing feveral papers of the late Tobias Mayer, and among them a catalogue of the right ascentions and declinations of 998 stars, which may be occulted by the moon and planets; the places being adapted to the beginning of the year 1756.

At the end of the first volume of "Aftronomical Observations made at the Royal Observatory at Greenwich," published in 1776, Dr Maskelyne, the present astronomer royal, has given a catalogue of the places of 34 principal stars, in right ascension and north polar distance, adapted to the beginning of the year 1770.

These being the result of several years repeated obfervations, made with the utmost care, and the best inftruments, it may be presumed are exceedingly accu-

In 1782, M. Bode of Berlin published a very extensive catalogue of 5058 of the fixed stars, collected from the observations of Flamsteed, Bradley, Hevelius, Mayer, De la Caille, Messier, Monnier, D'Arquier, and other astronomers; all adapted to the beginning of the year 1780; and accompanied with a celestial atlas or set of maps of the constellations, engraved in a most delicate and beautiful manner.

To these may be added Dr Herschel's catalogue of double stars printed in the Phil. Trans. for 1787 and 1783; Messier's nebulæ and clusters of stars, published in the Connoissance des Temps for 1784; and Herschel's catalogue of the same kind, given in the Phil. Trans. for 1786.

In 1789 Mr Francis Wollaston published "A Specimen of a General Astronomical Catalogue, in Zones of North polar Distance, and adapted to January 1. 1790." These stars are collected from all the catalogues before mentioned, from that of Hevelius downwards. This work contains five distinct catalogues; viz Dr Maskelyne's new catalogue of 36 principal stars; a general catalogue of all the stars, in zones of northpolar distance; an index to the general catalogue; a catalogue of all the stars, in the order in which they pass the meridian; and a catalogue of zodiacal stars, in longitude and latitude.

Finally, in 1792, Dr Zach published at Gotha, Tabulæ Motuum Solis; to which is annexed a new catalogue of the principal fixed stars, from his own observations made in the years 1787, 1788, 1789, 1790. This catalogue contains the right ascensions and declinations of 381 principal stars, adapted to the beginning of the year 1800.—Hutton's Mathematical Distinuary.

Besides these two methods of forming catalogues of the stars, Dr Herichel has conceived a new one, in which the comparative brightness of the stars is accu-

Catalogue rately expressed. It is long since astronomers were first of the Stars, led to arrange the stars in classes of different magnitudes by their various degrees of brilliancy or luftre. Brightness and size have at all times been considered as synonymous terms; so that the brightest stars have been referred to the class comprehending those of the first magnitude; and as the subsequent orders of stars have been supposed to decrease in lustre, their magnitude has been determined in the fame decreafing progression: but the want of some fixed and satisfactory standard of lustre has been the fource of confiderable confusion and uncertainty in settling the relative magnitudes of the stars. A flar marked 1. 2m. is supposed to be between the first and fecond magnitude; but 2. 1 m. intimates, that the star is nearly of the second magnitude, and that it partakes fomewhat of the luftre of a ftar of the first order. Such fubdivisions may be of fome use in afcertaining stars of the first, second, and third classes; but the expressions 5 m, 5.6 m, 6.5 m, 6m, must be very vague and indefinite. Dr Herschiel observes that he has found them fo in fact; and he therefore confiders this method of pointing out the different luftre of stars as a reference to an imaginary standard. It any dependence could be placed on this method of magnitudes, " it would follow, that no less than eleven stars in the constellation of the Lion, namely, $\beta \sigma \pi \xi$ A b c d 54, 48, 72, had all undergone a change in their lustre fince Flamsteed's time: For if the idea of magnitudes had been a clear one, our author, who marked \$ 1.2 m. and 7 2 m. ought to be understood to mean that & is larger than ?; but we now find that actually γ is larger than β . Every one of the eleven stars (fays Dr Herschel) which I have pointed out may be reduced to the fame contradiction."

The author has pointed out the instances of the infufficiency of this method, and of the uncertain conclufions that are deduced from it, in determining the comparative brightness of stars found not only in Mr Flamsteed's catalogue, but also in the catalogues of other astronomers. It is fufficiently apparent that the present method of expressing the brightness of the stars is very descrive. Dr Herschel therefore proposes a different

mode, that is more precise and fatisfactory.

"I place each flar (he fays), instead of giving its magnitude, into a fhort feries, constructed upon the order of brightness of the nearest proper stars. For instance, to express the lustre of D, I say CDE. By this short notation, instead of referring the star D to an imaginary uncertain standard, I refer it to a precise and determined existing one. C is a star that has a greater lustre than D, and E is another of less brightness than D. Both C and E are neighbouring stars, chosen in fuch a manner that I may fee them at the same time with D, and therefore may be able to compare them properly. The lustre of C is in the same manner ascertained by BCD; that of B by ABC; and also the brightness of E by DEF; and that of F by EFG.

"That this is the most natural, as well as the most effectual way to express the brightness of a star, and by that means to detect any change that may happen in its lustre, will appear, when we consider what is requisite to alcertain luch a change. We can certainly not wish for a more decifive evidence, than to be affured, by actual infpection, that a certain star is now no longer more formerly compared; provided we are at the same time directing changes."

affured that those other stars remain fill in their former Catalogue unaltered luftre. But if the flar D will no longer of the Stars, stand in its former order CDE, it must have undergone a change; and if that order is now to be expressed by CED, the star has lost some part of its lustre; if, on the contrary, it ought now to be denoted by DCE, its brightness must have had some addition. Then, if we should doubt the stability of C and E, we have recourse to the orders BCD and DEF, which express their lustre; or even to ABC and EFG, which continue the feries both ways. Now having before us the feries BCDEF, or if necessary even the more extended one ABCDEFG, it will be impossible to mistake a change of brightness in D, when every member of the series is found in its proper order except D."

In the author's journal or catalogue, in which the order of the luftre of the stars is fixed, each star bears its own proper name or number, e.g. " the brightness of the star & Leonis may be expressed by & & Leonis, or better by 94-68-17 Leonis; thefe being the numbers which the three above stars bear in the British

catalogue of fixed ftars."

This method of arrangement occurred to Dr Herfchel fo early as the year 1782; but he was diverted from the regular pursuit of it by a variety of other aftronomical engagements. After many trials, he proposed, in the Transactions of the Royal Society of London for 1796, the plan which appeared to him the most eligible. It is as follows :- Instead of denoting particular stars by letters, he makes use of numbers; and in his choice of the stars which are to express the lustre of any particular one, he directs his first view to perfect equality. When two stars feem to be similar both in brightness and magnitude, he puts down their numbers together, separated merely by a point, as 30.24 Leonis; but if two stars, which at first feemed alike in their lustre, appeared on a longer inspection to be different, and the preference should be always decidedly in favour of the fame star, he separates these stars by a comma, thus, 41,94 Leonis. This order must not be varied; nor can three fuch stars, as 20, 40, 39, Libræ, admit of a different arrangement. If the state of the heavens should be such as to require a different order in these numbers, we may certainly infer that a change has taken place in the luftre of one or more of them. When two Lars differ very little in brightness, but so that the preference of the one to the other is indifputable, the numbers that express them are scparated by a short line, as 17-70 Leonis, or 68-17-70 Leonis. When two ftars differ fo much in brightness, that one or two other stars might be interposed botween them, and still leave fufficient room for distinction, they are distinguished by a line and comma, thus, -, or by two lines, as 32 -- 41 Leonis. A greater difference than this is denoted by a broken line, thus - - - 29 Bootis. On the whole, the author observes, the marks and diffinetions which ke has adopted cannot possibly be mistaken; " a point denoting equality of lustre; a comma indicating the least perceptible difference; a short line to mark a decided but finall fuperiority; a line and comma, or double line, to express a considerable and striking excefs of brightness; and a broken line to mark any other superiority which is to be looked upon as of no or lefs bright than fuch other stars to which it has been use in estimations that are intended for the purpote of

The difficulties that attend this arrangement are not the Stars diffquifed; but the importance and utility of it more than compensate for the labour which it must necessarily require. By a method of this kind, many discoveries of changeable and periodical stars might probably have been made, which have escaped the most diligent and accurate observers. We might then, as the author suggefts, be enabled to refolve a problem in which we are

all immediately concerned.

"Who, for instance, would not wish to know what degree of permanency we ought to ascribe to the lustre of our fun? Not only the stability of our climates, but the very existence of the whole animal and vegetable creation itself, is involved in the question. Where can we hope to receive information upon this subject but from altronomical observations? It it be allowed to admit the fimilarity of stars with our fun as a point established, how necessary will it be to take notice of the fate of our neighbouring funs, in order to guess at that of our own! That flar, which among the multitude we have dignified by the name of fun, to-morrow may flowly begin to undergo a gradual decay of brightness, like β Leonis, « Ceti, « Draconis, & Uriæ majoris, and many other diminishing stars that will be mentioned in my catalogues. It may fuddenly increase, like the wonderful star in the back of Cassiopea's chair, and the no less remarkable one in the foot of Serpentarius; or gradually come on like & Geminorum, & Ceti, & Sagittarii, and many other increasing stars, for which I also refer to my catalogues; and, lastly, it may turn into a periodical one of 25 days duration, as Algol is one of three days, S Cephei of five, & Lyræ of fix, Antinoi of feven days, and as many others as are of various periods."

Having thus explained the general principle on which this catalogue is formed, as we find it in the author's first memoir on the subject, we must refer the reader to the Doctor's own account for its particular arrangement; observing only that the catalogue subjoined comprehends nine conftellations, which are arranged in alphabetical order, with the comparative brightness of the stars accurately stated. In a subsequent paper, published in the tam; volume, he has completely verified the ntility of his method by experience, and flewn that there is no permanent change of luftre in the flars. In the notes to his first catalogue he mentioned a Herculis as a periodical flar. By a feries of observations on this Aar, compared with x Ophiuchi, which was most conveniently fituated for his purpose, he has been able not only to confirm this opinion, but to afcertain its period. His observations are arranged in a table, by means of which he determines that this flar had gone through four fuccessive changes in an interval of 241 days; and there:ore the duration of its period must be about 60 days and a quarter. This fact concurs with other circumitances in evincing the rotatory motion of the stars on their axes. "Dark fpots, or large portions of the furface, less luminous than the rest, turned alternately in certain directions, either towards or from us, will account for all the phenomena of periodical changes in the lustre of the stars, fo fatisfactorily, that we certainly need not look out for any other cause." If it be alleged that the periods in the change of lustre of some flars, fuch as Algol, & Lyræ, & Cephei, and " Antinoi, are short, being only 3, 5, 6, and 7 days respectively; while those of o Ceti, and of the changeable star in Hy-

dra, and that in the neck of the Swan, are long, z. Catalogue mounting to 331, 394, and 497 days; and that we of the Stars cannot ascribe phenomena fo different in their duration Catharine. to the same cause—it may be answered to this objection, that the force of it is founded on our limited acquaintance with the state of the heavens. To the 7 stars, the periodical changes of which were before known, we may now add a Herculis, which performs a revolution of its changes in 60 days.

"The step from the rotation of a Herculis to that of c Ceti is far less considerable than that from the period of Algol to the rotation of a Hereulis; and thus a link in the chain is now supplied, which removes the objection that arose from the vacancy." The rotation of the fifth satellite of Saturn is proved by the change obfervable in its light; and "this variation of light, owing to the alternate exposition of a more or less bright hemisphere of this periodical fatellite, plainly indicates, that the fimilar phenomenon of a changeable ftar arifes from the various lustre of the different parts of its furface, succeffively turned to us by its rotatory motion."

Besides, we perceive a greater similarity between the fun and the stars, by means of the spots that must be admitted to exist on their surfaces, as well as on that of

Dr Herschel farther observes, that the stars, besides a rotatory motion on their axes, may have other movements; " fuch as nutations or changes in the inclination of their axes; which, added to bodies much flattened by quick rotatory motions, or furrounded by rings like Saturn, will easily account for many new phenomena that may then offer themselves to our extended views." To this paper is likewife subjoined a catalogue of nine constellations; and the author promises to give the whole of them in fuccessive short catalogues on the same

CATENARIA, or CATENARY CURVE. Sec Ena

cycl. and ARCH in this Supplement.

CATHARINE II. empress of all the Russias, acti ed fo conspicuous a part on the theatre of the world; possessed such uncommon powers of mind, highly cultivated by science and literature; and was such a patroness of science and literature in others-that it cannot be deemed foreign from a work of this nature to give fome account of the principal events of her more private life.

SOPHIA AUGUSTA FREDERICA, who, upon her marriage to the grandfon of Peter the Great, assumed the name CATHARINA ALEXIEVNA, was born at Stetlin on the 2d of May 1729. Her father was Christian Augustus, prince of Anhalt Zerbst-Dornburg, at that time major general in the Prussian service, commander in chief of the regiments of infantry, and governor of the townand fortreis of Stettin. Her mother, who was born princess of Holstein Eutin, was a woman of great parts and beauty of nearly the same age with the prince royal of Pruffia, afterwards Frederic the Great, with whom the kept up a regular correspondence, and who afterwards contributed to the aggrandifement of her daughter. This accomplished princess took upon herself the care of educating the young Sophia, whom the brought up in the simplest manner, and would not suffer to exhibit the least tymptoms of that pride to which she had some propentity from her earliest childhood. The consequence of this talutary restraint was, that good humour,

Catharine, mour, intelligence, and spirit, were even then the stri- which the courtiers quickly discovered, and were at Cathar king features of her youthful character. Being naturally addicted to reading, to reflection, to learning, and to employment, she was taught the French and other fashionable languages; and was instructed to read such books chiefly as might make her acquainted with hiltory and with the principles of science; whilst the doctrines of the Lutheran religion were carefully explained to her by a divine, who little thought how foon his illustrious pupil would embrace another faith.

The Empress Elizabeth, who then swayed the sceptre of Russia, had in early life been promised in marriage to the young prince of Holstein-Eutin, brother to the princess of Anhalt Zerbst; but at the instant when the marriage was about to be celebrated, the prince fell fick and died. Elizabeth, who loved him to excess, became inconfolable, and in the bitternels of her grief made a vow of celibacy. This vow, though fenfual, and even lascivious, he kept so far as never publicly to acknowledge any man as a husband; and upon her ascending the throne of her ancestors, she called her nephew the Duke of Holstein Gottorp to her court, where he was folemnly proclaimed, when fourteen years of age, Grand Duke, with the title of Imperial Highnels, and declared successor to the Empress Elizabeth. To secure the fuccession in the family of Peter the Great, the Emprels was very defirous to have her nephew married; and the princels of Anhalt-Zerbst, not ignorant of the tender remembrance which she still preserved for her brother, conceived the idea of placing, by means of it, her daughter on the throne of Russia. She communicated her plan to the king of Pruffia, who not only applauded it, but lent her his affistance to carry it into execution.

Full of ambitious hopes, therefore, the princess repaired with her daughter to St Pertersburgh, where she was received with friendship by Elizabeth, and where the young Sophia foon made a confiderable impression on the mind of the Grand Duke. As Peter was well made, of a good figure, and, though uneducated, not destitute of natural talents, the attachment became reciprocal; and the princels of Zerbst, throwing herself at the feet of the empress, affured her, that the two lovers were attached to each other by a paffion unconquerable; and calling to her mind the love which she had herself borne to the prince of Holstein, conjured her to promote the happiness of that prince's niece. The stratagem fucceeded. The choice of Elizabeth was next day announced to the council and to the foreign ministers; and preparations were made for celebrating the marriage with a magnificence worthy of the heir of the throne of the Ruffias. In the mean time the Grand Duke was feized with the small pox. from which, tho' he recovered, it was with fuch a change of features, as rendered him, from being comely, almost hideous, and converted the love of the young princess of Anhalt, if indeed she ever felt for him that passion, into horror and difgust. She was not, however, of a disposition to let a disfigured countenance frighten her from a throne. She embraced the Greek religion, changed her name from Sophia Augusta Frederica to CATHARINA ALEXI-EVNA, and with the entire approbation of Elizabeth was married to her nephew the Grand Duke.

For some time this ill-matched pair lived together, though without love, yet on terms apparently decent; but a mutual dislike gradually took place between them,

pains to foment into hatred. Peter was now ugly, and his mind was uninformed. Catharine, it not a beauty, was at least a lovely woman, and highly accomplished. She could find no entertainment in his convertation, and he felt himself degraded by her superiority. A faction was formed at court, headed by the great chancellor Bestuchess, to exclude the Grand Duke from the throne, and to place Catharine at the head of affairs; and to accomplish this end, every art was employed to fill the feeble mind of the empress with jealoufies of her nephew, and with a contempt of his character. He was reprefented at one time as extremely ambitious, and capable of the most daring enterprises, to get immediate posseifion of the throne; and at another, as a wretch given up to drunkennels and to every unprincely vice.

The confequence of the first of these acculations was, that he was kept at a diffance from his aunt, and a stranger to public affairs; and being wholly unemployed, that time which his education had not fitted him to fill up with reading, reflection, and rational conversation, hung fo heavy on his mind, that it was no difficult matter for those diffipated young men, who were placed about him for that very purpole, to initiate him in the habits of drunkenness and the other mean practices to which it was pretended he had long been devoted. In such a school, it was no wonder that he became a proficient in grovelling diffipation; or that, being unpolished, and even of rude manners, he chose for his companions some of the lowest of the people.

Catharine, in the mean time, languished for that happiness which she could not find in the society of her She was fond of pleasure; but it was that comparatively refined pleature which the had enjoyed at the court of Berlin. She loved balls music, and elegant conversation, and could take no share in the drunken revels of Peter. Among the young men with whom he was furrounded, his chamberlain Soltikoff was particularly remarked for the elegance of his taste and the graces of his person; and though yet scarcely more than a boy in years, he was faid to have obtained the favours of feveral ladies of the court. Success had made him confident and ambitious; and his ambition prompted him to aspire at making a conquest even of the Grand Duchefs. By fludying her tafte, and contriving to amute her, he was at last fuccessful; and obtained from her Imperial Highness every favour which he could wish: but he enjoyed not his fortune with moderation, and his enemies contrived to get him placed in an honourable office at a distance from the court. He was commissioned to repair to Stockholm, with the title of Envoy Extraordinary, to notify to the king of Sweden the birth of Paul Petrovitch, of whom the Grand Duchess had just been delivered *. The prefun ptuous Solti- * Oct. 1. koff, proud of the employment, fet off with hafte to 1754-Sweden, and left it with equal speed. But scarcely had he quitted Stockholm, on the wing of love and ambition, when he was stopped on the road by a courier, who put into his hands an order for him to go imme-

of minister plenipotentiary from the court of Ruffia. Catharine for some time preserved her attachment to the exiled chamberlain; but all at once the presence of a itranger, whom fortune had brought to the court of Russia, made her forget the lover whom she no longer

diately to Hamburgh, and there to relide in the quality

C varine, saw. This person was Stanislaus Poniatowsky, the late king of Poland, who first made his appearance at St Peterfburg in the train of the British ambassador, and very quickly gained the affections of the Grand Duchefs. In carrying on this intrigue, the lovers were not fo cautious as to deceive the eyes of the envious courtiers, who reported to the empress not only all that they faw, but whatever they suspected. Elizabeth was incensed, and commanded Poniatowsky to quit without delay the dominions of Russia. 'The accomplished Pole obeyed; but foon returned clothed with a character which made him in some degree independent of the empress.

The Count de Bruhl, then prime minister to the king of Poland, faw of what importance it was to his mafter to have a powerful interest at the court of Rusfia. He was likewife no stranger to the passion which the Grand Duchels entertained for Poniatowsky; and having got that nobleman decorated with the order of the White Eagle, he sent him back to St Petersburgh in the quality of minister plenipotentiary from the republic and king of Poland. Nor was this all that Bruhl did for the two lovers. Being informed by the chancellor Bellucheff, that the Grand Duke and Grand Duchess were languishing in a penury unworthy of their rank, he remitted to Poniatowsky 6000 ducats, to be employed in such a manner as he might judge best for fecuring the favour of the prince and his confort. The ambassador profited by these counsels and benefactions. He was already fure of the Grand Duchels's heart, and he very quickly gained the favour of her husband. He talked English and German with him; drank, smoked, abuted the French, and extolled the king of Pruffia with unlimited praise.

The Grand Duchess was so blinded by her passion, that she was never without Poniatowsky in her company. She devoted to him the whole of her time; and she made this intimacy fo little a fecret, that public report was loud to her prejudice. In the mean time she was ebruary delivered of the Princets Anne+, who lived only fifteen months The Grand Duke was the only person about court who feemed to know nothing of what was paffing. His whole time was occupied in copying, with fervile affectation, the air, the manners, the tone of the king of Prussia; and in dressing a litle army at Oranianbaum in the Prussian uniform. His eyes, however, were at last opened. Some of the courtiers, from hatred to the chancellor, who countenanced the intrigue between the Grand Duchels and the Polish ambassador, roused his jealoufy in order to destroy their enemy. They fucceeded. He forbade his wife to be feen with Poniatowsky, and prevailed with the empress to deprive the chancellor of his office, and to banish him to an estate

which he had 120 versts beyond Moscow. Catharine had now to support at once the aversion of her husband, the indignation of the empress, the infulting disdain of a court, which a few days before was lavish of its assiduities and smiles; and what afflicted her most of all, the dread of losing for ever her favourite Poniatowsky. Her courage, however, did not forsake her. Poniatowsky was indeed recalled, and left Russia, after fuffering some deserved indignities from the Grand Duke, who about this time formed a connection with

one of the daughters of the Senator Vorontzoff, brother Carharine. to the new chancellor. This lady, Elizabeth Romanovna Vorontzoff, was elder fister to the Princess Dashkoff, who acted to conspicuous a part in the revolution which fet the crown on the head of Catherine. She was beautiful, but vain; and possessed not either the wit or the understanding of her filter.

In the mean time the health of the empress visibly declining, Catharine was very defirous of being reconciled to her: but the irritated sovereign would listen to no accommodation, except on terms too humiliating for the haughty spirit of the Grand Duchess. Catharine, therefore, absented herself from court, and asked permiffion to retire into Germany. This, as the had foreteen, was refused. Elizabeth was too fond of the young Paul Petrovitch to permit the departure of his mother, and thereby expose him to the danger of being at some future period declared illegitimate. She took the Grand Duchess again into favour; and it is thought, that had she lived a little longer than she did, she would have excluded Peter from the throne, and declared Paul her immediate successor.

Whill the empress was meditating the aggrandifement of the young prince and his mother, the Grand Duke had conceived a plan for degrading them both. He had resolved, at the moment his aunt should close her eyes, to affemble his troops, to get himself proclaimed emperor, to repudiate the Grand Duchefs, to declare the young Paul Petrovitch illegitimate, and publicly to marry his mistress Elizabeth Romanovna Vorontzoff. We have shown elsewhere (see Russia, n° 72. Encycl.) how this plan, when almost ready to be carried into execution, was betrayed to Catharine, who, ever fince her caballing with the Chancellor Bestuchess, had resolved, by some means or other, to snatch the sceptre from the feeble hand of her husband. At present, we believe she was not acquainted with it; and though she had, she could not now have turned it to her advantage, as her party, ever fince the diffgrace of Bestuchess, was without a leader of any abilities.

Amid these distractions caused by the prospect of the death of the empress, and the known hatred of the Grand Duke and Duchels to each other, Count Panin, preceptor to the young prince, devoted himfelf entirely to Catharine. He wished to see her p ssessed of all the power of the empire; but he was afraid to proceed to. the extremity to which she proposed to go, and to deprive Peter of the name of Emperor. He contrived therefore to procure an apparent reconciliation between the Grand Duke and his confort, as well as between him and his aunt Elizabeth; and he had almost persuaded the filly prince not to assume the sovereign power on the death of the empress, till he should be solemnly invested with it by a decree of the senate. Could he obtain this point, he knew that the power of Peter would be limited, and the authority fecured to his wife and his son. He was, however, disappointed. Catharine herfelf disapproved of this plan, and concurred with the real friends of her hulband in advising him "to conform to established custom in assuming the reins of empire."

He had hardly received this advice when word was brought him that the Empress Elizabeth was dead (A);

⁽A) Christmas-day 1761 according to the Russian calendar, or the 5th of January 1762 according to ours,

Catharine, and the courtiers pressed in crowds about him. He vations; and found himself obliged suddenly to recal Cathar accosted them with dignity, received the oaths of the officers of his guard, and feemed at once to have laid aside his weakness. In an hour he got on horseback, traversed the streets of St Petersburg, and distributed money among the multitude and the foldiers. He had been fo treated by his aunt, that he could not possibly be grieved at her death; but in paying the last duties to her remains, he betrayed no indecent elation. The first actions of his reign were prudent and patriotic, and fuch as would have done honour to a greater prince. He appeared to be reconciled to his wife, in whose company he fpent much of his time; he recalled from prison and banishment 17,000 persons, some of them of rank and of great talents, who had been the victims of Elizabeth's jealous timidity; he permitted the nobility to bear arms or not at their own discretion, freeing them at the fame time from the extreme fervitude under which they had been held by his immediate predecessors; and he abolished the secret committee, an infamous inquifitorial tribunal, which ever fince the reign of the father of Peter the Great had been the chief engine of Rushan hearts which he was losing.

He neglected, however, one thing; which, among the people over whom he was appointed to reign, would have contributed more to the security of his throne than all the wife and beneficent edicts which he had published. He made no preparations to be crowned at Mofcow. Instead of complying with this ancient ceremony, and humouring the prejudices of his superflitious subjects, he thought of nothing but of war with Denmark, and of a personal interview with the king of Prussia in Germany. His admiration of that great monarch hurried him indeed into the most extravagant follies. Not contented with giving him peace, and entering into an offensive and defensive alliance with him, he had the meanness to solicit a commission in his army, and to accept of the rank of major-general. Of this title he feemed more vain than of that of Emperor of all the Ruffias. He constantly wore the Prussian uniform; introduced among his troops the Prussian discipline, which, though better than their own, was difagreeable, because it was new, and much more because it was German; and he raifed his uncle, a man of no military talents, and a foreigner, to the dignity of generalissimo of the Rusfian armies; giving him at the fame time the particular command of the horse-guards, a body of men which had mever before been under any command but that of the supreme head of the empire. Nor did his infatuated predilection for Germany, a country abhorred by the Russians, stop even here: He disbanded the noble guards which had placed Elizabeth on the throne, difmiffed the horse guards from the service which they performed at court, and fubflituted his Holstein guards

Whilst he was thus alienating from himself the affections of the army, he contrived to difgust another order of men, whose attachment he should have laboured above all things to retain. He was at pains to shew his preference of the Lutheran faith and worship to the doctrines and ceremonies of the Greek church; he attempted to make fome alterations in the drefs of the monks; he annexed great part of the possessions of the church to the domains of the crown; and he banished the archbishop of Novogorod, who opposed these innohim.

He had now returned to his former courses. He thut himself up for whole days with his mistress and drunken companions; he compelled the nobility and ladies of the court to fit in company with buffoons and comedians; he infulted every foreign minister but the ministers of Great Britain and Proffia; and he made no fecret of his intention to repudiate the empress, declare Paul Petrovitch illegitimate, and marry the Countels Vorontzoff. Convinced, however, as it would feem, that he could not be a father, he refolved to adopt Prince Ivan, the descendant of the elder brother of Peter the Great, whom Elizabeth had dethroned and confined in prison, to declare him his fuccessor, and to unite him in marriage with the young princess of Holstein Beck, who was then at St Petersburgh, and whom he cherished as his daughter.

This inconfiltent and weak conduct of the emperor turned the attention of all orders of men to the empress, who made it her sole employment to gain those Instructed from her infancy in the arts of diffimulation, it was not difficult for her to affect, in the fight of the multitude, fentiments the most foreign to her mind. The pupil of the French philosophers put on the air of a bigot to the most fupersitious ceremonies of the Greek religion, and treated the ministers of that religion with the profoundest reverence. And whilst her husband was getting drunk amidst a rabble of buffoons, and disgusting every person of decency who approached him, she kept her court with a mixture of dignity and affability, which attracted to her all who, by capacity, courage, or reputation,

were capable of ferving her.

Correct, however, as her public conduct appeared, her private life was not less licentious than formerly. While yet Grand Duchefs, she liad formed a very tender connection with Gregory Orloff, a man of mean birtli, and of no education, but possessed at once of personal beauty and the most daring courage. He had an inferior commission in the artillery, while his two brothers were common foldiers in the regiments of guards. The intrigue which she carried on with him was known only to one of her women named Catharine Ivanovna; nor did Orloff himself for some time suspect the rank of the lady who fo lavifuly conferred upon him her favours in fecret. At last finding him intrepid and discreet, she discovered herself, unvailed to him all her ambitious defigns, and eafily prevailed with him and his brothers to enter with zeal into her conspiracy against the emperor. Orloff likewife gained over Bibikoff his friend, a Lieutenant Paffick, with other officers; and by their means eafily scduced some regiments of the guards. The Princels Dashkoff was strongly attached to Catharine, we believe, from worthy motives, and had frequent meetings with Orloff on the business of the conspiracy, without suspecting that he was so much as known to the empress. Count Panin, too, and the Hetman of the Kofacks, were determined to tumble Peter from the throne; but they were not inclined to go all the lengths proposed by Catharine and her two savourites. Hoping to enjoy the actual power of the empire themsolves, they were for declaring Paul Petrovitch emperor in the room of his father, and conferring upon his mother the name and authority only of regent; while

harine the princess and Orloss, knowing the fentiments and wishes of the empress, were resolved to vest her with fovereign power, or to perish themselves in the hazardous attempt.

In the mean time the anniverfary of the patron faints of Russia was at hand, when Peter had determined, at the conclusion of the festival, to divorce the empress, thut her up in prison, declare her fon illegitimate, and publicly marry his mistress. As they who plan a confpiracy are always more vigilant than those against whom it is directed, the friends of Catharine were carefully informed of all that paffed about the emperor, whilft he was kept in total ignorance of their proceedings. It was therefore necessary for them to unite in the same or divisions would involve them all in one common ruin. The empress contrived to bring over the Hetman entirely to her views; and the Prince's Dashkoff, by the facrifice, it has been faid, of her charms, found little difficulty in reconciling Count Panin to the same measures. They now agreed to seize the Tzar on his arrival at Peterhoff, an Imperial palace on the shore of the Gulf of Cronftadt, where he proposed to celebrate the approaching festival; and they were waiting impatiently for the moment of action, when all at once their plot was difcovered.

Paffick, who has been mentioned among the confpirators, had gained the foldiers of the company of guards in which he was a lieutenant; but one of them, who thought that his captain was in the fecret, asked that officer one evening, When they were to take up arms against the emperor? The captain, surprised, had recourse to diffimulation, and easily drew from the soldier all that he knew of the conspiracy. It was nine o'clock at night. Passick was put under arrest; but found means to flip into the hands of a man who had been placed as a fpy over him by the Princess Dashkoff, a scrap of paper containing these words, "Proceed to execution this instant, or we are undone." The man was defired to carry it to the Hetman, by whom he would be handsomely rewarded; but he hurried with it to the princess, who instantly communicated the intelligence to the other conspirators. She herself put on man's apparel, and hastened to the place where she was accustomed to meet Orloff and his friends; where she found them, as impatient as herself to carry their plot into immediate execution.

During this awful crifts the empress was at Peterhoff, at the distance of 25 versts from St Petersburgh; and one of the brothers of Gregory Orloff, named Alexius, undertock to find her out, whilst he himself, with his other brother and Bibikoff his friend, repaired to the barracks for the purpose of instructing the soldiers of their party how to act on the first fignal. Alexius Orloff carried with him a front note from the Princess Dashkoff, but neglected to deliver it; and the empress, being suddenly roused from a found sleep, was much alarmed, when the faw at the fide of her bed a foldier of whom she knew nothing. Her alarm was in-crezsed when the stranger said, "Your majesty has not a moment to lofe; get ready to follow me;" and inflantly disappeared. She rose, however, and calling her woman Ivanovna, they difguifed themselves in such a manner that they could not be known by the fentinels about the palace; and the foldier returning, they hur-Suppl. Vol. I. Part I.

ried with him to a coach which was waiting at the gar. Catharine, den gate. Orloff took the reins, but drove with fuch fury that the horses soon fell down; and they were obliged to travel part of the way on foot. They had not, however, gone far, when they met a light country cart; and she who was aspiring to the throne of the greatest empire in the world, was glad to enter the capital of that empire in this humble vehicle.

It was feven in the morning when fhe arrived in St Petersburgh: and to the foldiers, who gathered about her in great numbers, she faid, that " her danger had driven her to the necessity of coming to ask their affiftance; that the Tzar had intended, that very night, to put her and her son to death; and that she had so great plan, and to carry it quickly into execution; for delay confidence in their dispositions, as to put herself entirely into their hands." They immediately shouted, "Long live the empress!" And the chaplain of one of the regiments fetching a crucifix, received their oaths

of fidelity.

The troops, however, were not unanimous in this 1evolt. Though Gregory Orloff was treasurer of the artillery, and well enough beloved by the foldiers, that corps refused to follow him until he should produce the orders of Villebois their general; and that officer, withheld either by fidelity to the emperor or by fear, prefumed to speak to Catharine of the obstacles which yet remained for her to furmount; adding, that she ought to have foreseen them. She haughtily replied, that " she had not feat for him to ask what she ought to have foreseen, but to know how he intended to act." "To obey your majesty," returned Villebois; and putting himself at the head of his regiment, he immediately joined the conspirators. So ripe indeed were the minds of all men for this revolt, that in the space of two hours the empress found herself surrounded by 2000 warriors, together with great part of the inhabitants of Peterfburgh; and with that numerous train of attendants she repaired to the church of Kafan, where the archbishop of Novogorod, fetting the Imperial crown on her head, proclaimed her fovereign of all the Ruffias, declaring, at the same time, Paul Petrovitch her successor.

Matters had now proceeded by much too far to admit of any compromise between Catharine and her husband : but had the infatuated Tzar put his affairs wholly into the hands of Marshal Munich, that intrepid veteran would have tumbled the empress from her throne almost as quickly as she had got possession of it. He acted, however, a very different part. Upon receiving intelligence of what had been done at St Petersburgh, he asked indeed the Marshal's advice, but suffered himfelf to be guided by his miftrefs and timid companious. Through their terrors and his own irrefolution opportunities were lost which could never be recovered; for though his Holstein guards, with tears in their eyes, fwore that they were all ready to facrifice their lives in his fervice, and though the old Marshal offered to lead them against the rebels, faying to the emperor, " I will go before you, and their fwords shall not reach you till they have pierced my body," he was perfuaded to treat with the empress, to acknowledge his misconduct, and to offer to share with her the sovereign power. At last he was weak enough to abandon his troops, and to furrender at discretion to his confort; whose creatures hurried him from Oranienbaum to Peterhoff, ftripped him of all his clothes, and after leaving him for fome

Catharine, time in his shirt, a butt to the outrages of an insolent Dashkoff sirst perceived it; and when she presumed to Catha foldiery, threw over him an old morning gown, and shut him up alone, with a guard at the door of his wretched * July 10. apartment. On the 29th of June, O. S. * 1762, Count Panin was fent to him by the empress; and after a long

conference, prevailed with him to write and fign a folemn refignation of his crown, and a declaration of his utter incapacity to govern fo great an empire.

The revolution was now complete, and Peter feemed to enjoy some composure of mind; but in the evening he was carried a prisoner to Ropscha, a small Imperial palace, at the distance of 20 versts from Peterhoff, where he was murdered on the 17th of July, just one week after his deposition. Of the manner of his death different accounts have been given. By fome he is faid to have been poisoned; by others, to have been strangled by one of the Orloffs; and a few have thought that he perished by the fame means as Henry VI. of England. Whether the empress was accessary to his death is not known; though it is certain, that fo far from making any inquiry after his murderers, she affected to believe that he had died naturally of the piles!

The first care of Catharine was to reward those who had been the principal actors in the revolt Panin was made prime minister; the Orloffs received the title of Count; and the favourite Gregory was appointed lieutenant-general of the Ruffian armies, and knight of the order of St Alexander Nefsky, the fecond order of the empire. Several officers of the guards were promoted, of whom 24 received confiderable effates; and among the foldiers, whom she treated with the greatest affability, brandy and beer were liberally distributed. The chancellor Bestuchess, who had been the most inveterate enemy of Peter, was recalled from his exile, restored to his rank of field marshal, and had an annual pension settled upon him of 20,000 rubles. To the friends of the emperor she behaved with great moderation. Prince George, whom he had constituted Duke of Courland, was indeed obliged to renounce his title; but the administration of Holstein was committed to him, and he ever after ferved the empress with zeal and fidelity.

The news of the revolution was foon spread over Europe; and none of the fovereigns, though they knew by what steps Catharine had mounted the throne, hefitated for a moment to acknowledge her title. She was not, however, at perfect ease in her own mind; nor was her right recognised by all her subjects. Tho' she published manifestos, setting forth the intentions of the late emperor towards her and her fon, which made refistance necessary; though in these papers she attributed her elevation to the wishes of her people and the providence of God; and though the called upon all who were fincerely attached to the orthodox faith of the Greek church, to consider the sudden death of Peter as the judgment of heaven in favour of the revolution - yet in it at last so cold a reception, that she very quickly returned to St Petersburgh.

Nor was this the only canfe of her uneafiness. The connection between Orloff and her became visible, and

expostulate with the empress on the meanness and imprudence of her passion, she was banished from the court to Moscow. Count Panin and the Hetman saw with indignation that they had dethroned the grandfon of Peter the Great, to aggrandise a rude and low born upstart. Cabals and conspiracies were entered into by high and low, both against Catharine and against her favourite; and it required all her abilities and firmness to preserve at once her throne and her lover. On one occasion she hoped to obtain from the Princess Dashkoff sufficient proof that Panin and the Hetman of the Kofacks were concerned in a plot which had just been discovered; and with this view she wrote to her a letter of four pages, filled with the most tender epithets and the most magnificent promites, conjuring her in the name of their long flanding friendship, to reveal what she knew of the recent conspiracies. With becoming magnanimity, the princess replied, " Madam, I have heard nothing; but if I had heard any thing, I should take good care how I spoke of it. What is it you require of me? That I should expire upon a scaffold? I am ready to mount it."

Catharine, despairing of conquering such a spirit, attempted to attach to her those whom she dared not to punish. Some of the inferior conspirators were banished to Siberia, while Panin and the Hetman, whom she most dreaded, received additional marks of her favour. In the mean time, to gain the affections of the people at large, she paid the utmost attention to the administration of justice; formed magnificent establishments for the education of the youth of both fexes; founded hofpitals for orphans, for the fick, and for lying in women; invited foreigners of all nations, possessed of any merit, to settle in different parts of her vast territories; increafed the naval force of the empire; and gave fuch encouragement to the cultivation of every elegant and ufeful art, that in the short space of a year and a half from her accession to the throne, the national improvement of

Russia was visible.

In the good fortune and glory of Catharine, no one rejoiced more fincerely than Count Poniatowsky. He appreached towards the confines of Ruffia, and wrote to her in the tenderest style of congratulation, requesting permission to pay his respects to her in the capital of her empire. It is not improbable that he flattered himself with the hopes that she would give him her hand in marriage, and thus raife him to the throne of the Tzars; but she had promifed to the Empress Elizabeth, that she would never again see the count; and to that promife she at present adhered. She wrote to him, however, in the most affectionate terms; and tho' she gave him no encouragement to repair to St Petersburgh, she assured him that she had other prospects in view for his aggrandifement, and that he might depend in the distant provinces no exultations were heard; both upon her perpetual friendship: and she soon appeared foldiers and peasants observed a gloomy silence. Even to be as good as her word. On the death of Augustus at Moscow, so great was the disaffection to Catharine's III. she raised her former favourite to the throne of government, that it was fome time before she could ven- Poland, in opposition to the wishes of the courts of ture to go to that city to be crowned; and she found Vienna and Versailles, as well as of a great majority of the Polish nobles. She defeated the intrigues of the two foreign courts by more skilfully conducted intrigues of her own; and, by pouring her armies into the republic, she so completely overawed the nuncios, that gave just offence to her other friends. The princefs of Poniatowsky was chosen by the unanimous suffrages of

and, on the 7th of September 1764, was proclaimed King of Poland and Grand Duke of Lithuania, by the

name of Stanislaus Augustus.

Whilst she was thus disposing of foreign kingdoms, the was kept under perpetual dread of being tumbled from the throne of her own vast empire. Her want of title to that throne was now feen by all ranks of her subjects: the good qualities of Peter the third were remembered, and his failings and faults forgotten. His fate was univerfally lamented; and, except the conspirators, who may be faid to have embrued their hands in his blood, there was hardly a Ruffian who did not regret that the fovereignty had paffed from the ancient family of the Tzars to a foreigner, allied only by mar-riage to the blood royal. Even the conspirators them-selves had lost much of their regard for Catharine. The princess of Dashkoff was a second time banished to Moscow; and, to magnify her own importance, she spoke freely of the means by which the empress, whom the accused of ingratitude, had been raised to the throne. The inhabitants of Moscow, who never favoure! the usurpation, were thus made ripe for a revolt. At St Petersburgh, Count Panin felt himself uneasy under the predominant influence of the favourite, and tried in vain to divert Catharine's affections to a new object. She received a few fecret vifits from a handsome young man, and then appointed him to a lucrative and honourable employment in some distant province of the empire; when Orloff recovered his former alcendency, which through his own careleffness he had nearly lost. In this state of the public mind, conspiracies were very frequent; and as the general object of them was to place on the throne prince Ivan, who was again languishing in the dungeon from which Peter had taken him, the empress had given to his guard an order, figned by her own hand, to put that unfortunate prince to death, should any attempt be made to liberate him from his prison. An attempt was made by a very inferior officer, as some have supposed, by the instructions of Catharine, and her bloody order was instantly obeyed. The affaffins were rewarded, and promoted in the army; but the officer who attempted to rescue the prince was condemned to death, and fuffered unexpectedly the fentence of the law. The brothers and fifters of Ivan, who had been kept in a prison different from his, were fent to Denmark; and, to provide them with necesfaries fuitable to their rank, the empress made them a present of 200,000 rubles, and paid annually to the maintenance of their dignity a pension of thirty thou-

The throne of Catharine was now firmly established by the death or renunciation of every person who was descended of the imperial family; and she had leisure to turn her thoughts to the aggrandifement of the empire. It was foon feen that this was the object which the had in view when the raifed Count Poniatowsky to the throne of Poland, and that she was not actuated on that occasion by any remains of her former attachment. We have elsewhere shown (fee Poland, Encycl. nº 98 -115) under what pretences she invaded the kingdom of him who had formerly been one of her most favoured lovers, and by what means she annexed great part of it to the territories of Russia. But it is not through

r some the diet which met for the election of a fovereign; ractor: It is not as a fovereign and heroine that her Catharine. life is entitled to a place in a general repolitory of arts, sciences, and miscellaneous literature, but as a patronela of art and of science, and as the legislatrix of a vast empire, who employed all her talents and all her power for the civilization of a great part of the human race.

Under the article Russia (Encycl.), we have mentioned the famous code of laws for a great empire, and the proposed convention of deputies from all the classes, which Catharine and the princess Dashkoff so artfully employed as means to bring about the revolution which scated the former on the throne. The states actually met in the ancient capital of the empire, and the fovereign's instructions for framing a new code of laws was read amidst reiterated bursts of applause. All present extolled the fagacity, the wifdom, the humanity of the cmpress; but fear and flattery had a greater share in theie exclamations than any just knowledge of the subject. The deputies of the Samoiedes alone had the courage to speak freely. One of them stood up, and, in the name of himself and his brethren, faid, "We are a simple and honest people. We quietly tend our reindeer. We are in no want of a new code; but make laws for the Russians, our neighbours, that may put a stop to their depredations." The following fittings did not pals fo quietly. A debate about the liberation of the boors was carried on with fuch warmth, that fatal consequences were to be apprehended; and the deputies were dismissed to their respective provinces in the manner which we have elfewhere related. Previous, however, to the diffolution of this affembly, the members were required to fignalize the meeting by fome conspicuous act of gratitude; and by a general acclamation, the titles of GREAT, WISE, PRUDENT, and Mother of the Country, were decreed to the emprefs. With assumed modesty she accepted only of the last, " as the most benign and glorious recompence for her labours and folicitudes in behalf of a people whom fhe loved."

For that people she did indeed labour, and labour most usefully. She introduced into the administration of justice the greatest reformation of which the half civilized state of Russia would perhaps admit. She spared neither trouble nor expence to diffuse over the empire the light of science, and the benefits of useful and elegant arts; and the protected, as far as the could, the poor from the oppressions of the rich. About the middle of 1767, she conceived the idea of fending several learned men to travel through the interior of her valt dominions, to determine the geographical position of the principal places, to mark their temperature, and to examine into the nature of their soil, their vegetable and mineral productions, and the manners of the people by whom they were inhabited. To this employment she appointed Pallas, Gmelin, Euler, and many others of the highest eminence in the republic of letters; from whose journals of these interesting travels large additions have been made to the general flock of uieful knowledge. This furvey of the empire, and the maps made from it, had Catharine done nothing elfe, would alone have been fufficient to render her name immortal. Well convinced in her own mind, that it is not fo much by the power of arms, as by precedence in science, that nations obtain a conspicuous place in her wars that in this article we mean to trace her cha- the annals of the world, with a laudable zeal she enCatharine. couraged artifts and scholars of all denominations. She granted new privileges to the two academies of sciences and the arts; encouraged such of the youth as had behaved well in these national institutes, to travel for farther improvement over Europe, by bestowing upon them, for three years, large pensions to defray their expence: and, to remove as much as possible the Russian prejudice against all kinds of learning, she granted patents of nobility to those who, during their education, had conducted themselves with propriety, and become proficients in any branch of useful or elegant knowledge. Still farther to encourage the fine arts in her dominions, the affigned an annual fum of 5000 rubles for the translation of foreign literary works into the Russian

> In the year 1768, the small-pox raged at St Petersburgh, and proved fatal to vast numbers of all ranks and of every age. The empress was desirous to introduce the practice of inoculation among her subjects; and refolved to fet the example by having herfelf and her fon inoculated. With this view, she applied for a physician from England: and Dr Thomas Dimsdale of Hertford being recommended to her, he repaired with his fon to the capital of Russia, where he inoculated first the empress, then the grand duke, and afterwards many of the nobility. The experiment proving fuccefsful, he was created a baron of the empire, appointed actual counsellor of state, and physician to her imperial majesty, with a pension of L. 500 sterling a-year, to be paid him in England, besides L. 10,000 which he immediately received. So popular was the empress at this period, that, by a decree of the fenate, the anniversary of her recovery from the small-pox was enjoined to be celebrated as a religious festival; and it has ever since been observed as such.

> She was now engaged in war with the Turks, of which a sufficient account for a work of this nature has been given under the title Turkey (Encycl.); but there was one transaction of her and her friends, of which no mention was made in that article, though it is of importance to him who would form a just estimate of her personal character.

We have noticed the fenfuality of the empress Elizabeth. She bore three children to the grand veneur Alexey Gregorievitch Razumoffsky, to whom, indeed, the is faid to have been clandestinely married. Of these children the youngest was a girl, brought up under the name of princess Tarrakanoff. Prince Radzivil, who has been mentioned in the article POLAND (Encycl.), irritated at Catharine's cruelties to his countrymen, conceived the project of placing the young princess on the throne of her ancestors; and, having gained over the perions to whom her education was entrusted, he carried her off to Rome as a place of safety. Catharine, in return, seized his large estates; and he and the princess were reduced to extreme poverty. Radzivil repaired to Poland in order to learn what could be done to forward his great enterprise; and scarcely had he arrived there when an offer was made to restore to him his possessions, upon condition of his carrying his ward to St Petersburgh. This he refused; but had the baseness to promise, that he would give himself no farther Cathar concern about the daughter of Elizabeth; and he was put in possession of all his estates.

By the instructions of the empress, Alexius Orloff, who nominally commanded the Russian sleet at the Dardanelles, repaired to Rome, got access' to young Tarrakanoff, and found means to perfuade her that all Ruf. sia was ready to revolt from Catharine, and place her on the throne of her mother. To convince her of his fincerity, he pretended to feel for her the tenderest and most respectful passion; and the unsuspicious lady was induced to accept of him as a husband. The ruffian who had affaffinated the grandfon of Peter the Great, did not hesitate to seduce and betray his granddaughter. Under pretence of having the marriage ccremony performed according to the rites of the Greek church, he suborned some subaltern villains to personate priests and lawyers; thus combining profanation with imposture against the unprotected and too confident Tarrakanoff.

Having been treated for some days, both at Rome and at Leghorn, with all the respect due to a sovereign, the unsuspecting princess expressed a wish to go on board a Russian ship of war. This was just what Orloff wanted. Attended by a numerous and obsequious train, the was rowed from the shore in a boat with magnificent enfigns, hoisted upon the deck of the ship in a splendid chair, and immediately handcuffed. In vain did she throw herself at the feet of her pretended husband, and conjure him by every thing tender which had passed between them. She was carried down into the hold; the next day the veffel failed for St Petersburgh; where, upon her arrival, the princess was shut up in the fortress; and what became of her fince was never known. Such were the means which Catharine ferupled not to employ in order to get rid of all pretenders to her throne.

Soon after this fervice rendered to her by Alexius Orloff, she dismissed his brother Gregory from her favour, and connected herself with Vassiltchikoff, a sublieutenant of the guards. The former favourite had indeed become insolent, and, as Catharine thought, ungrateful. He aspired to nothing less than the throne. From love to himself and to a son which she had bornto him, she offered to enter into a secret marriage; but with this propolal the proud prince (A) was not fatisfied, and hoped that his refusal would impel her to receive him publicly as her husband and partner in power. He was mistaken. She divested him of all his employments; but gave him a pension of 150,000 rubles, a handsome service of plate, and an estate with 6000 peafants upon it; and, thus enriched, he fet out upon a journey through various parts of Europe. He returned, however, much sooner than was expected; the new favourite was handsomely rewarded, and sent to a distance; Orloff was restored to all his offices, and his baleful influence was again felt.

He attempted to persuade the empress to dismiss Panin from the court; but the grand duke interposed in behalf of his old preceptor; and, for once, Catharine listened to the entreaties of her son. When a dreadful rebellion, under a Kofak of the name of Pugetshoff,

e inine who pretended to be Peter III. escaped from his asfassins, was shaking the throne to its foundation-the influence of Orloff was fuch as to prevent the empress, for some time, from employing her ablest general against the rebels, because that general was Panin, brother to the minister. Danger, however, at last prevailed over the favourite: Panin was fent against Pugetshoff; the rebellion was crushed; and Catharine found leifure to give tomething like a legal conftitution to the empire. In that work, the laws and regulations established for the government of the various provinces, and for the equitable administration of justice through the whole of her vast dominions, evinces the greatest wisdom and fagacity in their author, as well as a proper regard to the practicable liberties and rights of men. In the capital, she established the most perfect police, by which the internal tranquillity of a great city was, perhaps, ever maintained; and whilst her private conduct was far from correct, she was acting in the capacity of fovereign, fo as to deferve, indeed, the appellation of Mother of her people.

To follow her through all her wars and intrigues with foreign courts, would fwell this article to the fize of a volume. Such a narrative, too, belongs rather to the history of Russia than to the memoirs of Catharine; in which it is the business of the biographer to develope the private character of the woman rather than to detail the exploits of the fovereign. Her partition of Poland, and afterwards the annihilation of it as an independent republic; her encroachments on the territories of the grand fignior; her formation of the armed neutrality; the influence which she maintained over the courts of Sweden and Denmark; and the art with which she threw the weight of Russia sometimes into the scale of Austria, and sometimes into that of Pruslia, just as the interests of her own dominions required the one or the other to preponderate-shew how admirably the was qualified to guide the helm of a great empire in all its transactions with foreign states. We speak not of the equity of her proceedings; for it must be confessed, that equity formed no barrier against her ambition; and that she never failed to subjugate those whom she pretended to take under her protection. Her ruling passion was to enlarge her own territories, already so very extensive; and, for the attainment of that object, she contrived the most judicious plans, which she executed with vigour. In this part of her conduct; however, she has been equalled by other monarchs; but in the zeal and the wisdom with which she endeavoured to introduce among her half lavage subjects the blesfings of knowledge and industry, she stands unrivalled, except, perhaps, by her predecessor Peter the Great.

Of this we need bring no other proof, in addition to what has been already trated, than that the founded in St Petersburgh alone thirty-one feminaries, where 6800 children of both fexes were educated at the annual expence to the government of 754,335 rubles. She fuperintended herfelf the education of her grandchildren, and wrote for them books of instruction. If it be true, that 'every man acquainted with the common principles of human action, will look with veneration on the writer who is at one time combating Locke, and at another making a catechism for children in their fourth year;" with what veneration should we look upon the empre's of Russia, could we torget the means by which she ob tained that elevation from which the frequently descend-

ed for a fimilar employment? This she did, not for her Catharines own descendants alone, but also for the children of others; of whom she had always a great number in her apartments, who shared in the instruction given to her grandchildren, and whose careffes she returned with ex-

treme complaifance.

Her greatest weakness was furely that gross passion which her panegyrists have dignified with the name of love: but to such an appellation it had no claim, if love be any thing more than a fexual appetite. Besides Gregory Orloff, the had not fewer than ten favourites after the death of her husband; and of these she feems to have felt a refined affection for none but Lanskoi, a young Pole of a very ancient family, and of elegant manners, and the famous Potemkin, to whom the is faid fecretly to have given her hand, and who preferved her friendship, if not her affection, to the end of his life. To Lanskoi, whose education had been much neglected, she condescended to become preceptrix; and as he made great progress in the acquifition of useful knowledge, she admired in him her own creation. Potemkin, though not amiable, deserved her favour for the fidelity and abilities with which he ferved her, both in the council and in the field; and in him, when she had ceased to look on him with the eyes of love, she respected the intriguing politician and intrepid commander, who had formed plans for driving the Turks out of Europe, and fetting her on the throne of Byzantium. Her other favourites had nothing to recommend them but masculine beauty and corporeal strength. One of them, however, thought it necessary to have a library in the grand house, of which the empress, up. on receiving him into favour, had made him a prefent; and defired the principal bookseller to fill his shelves; The man asked him what books he would please to have. "You understand that better than I (replied the favourite); that is your business. You know the proper affortments; I have destined a large room to receive them. Let there be large books at the bottom, and smaller and smaller up to the top; that is the way they stand in the empress's library!" In the converfation of fuch men, the cultivated mind of Catharine could enjoy no interchange of fentiments.

We know not whether that more than Afiatic magnificence, which the displayed on every public occasion, thould be considered as an instance of weakness or of wildom. If she delighted in balls, and masquerades, and fumptuous entertainments, and drefs loaded with jewels and every kind of fplendid ornament, for their own fakes, she betrayed a weakness unworthy of that fovereign who held in her hand the balance of Europe, and at whose nod the greatest powers of Asia trem-bled: but if she introduced such splendor into her court merely to divert the attention of the Ruffians from the means by which she got possession of the throne, and to ween them from their own favage and flovenly manners; even this may perhaps be confidered as one of her most masterly strokes in politics.

Her ambition was boundless; but, if such a phrase may be allowed, it was not always true ambition. When the French republic had established itself on the ruins of monarchy, and was propagating new theories of government through all Europe, true ambition would furely have led the autocratrix of the north to unite her forces with those of the coalesced powers, in order Catharine, to crush the horrid hydra before its anarchical principles could be introduced among her own barbarous fubjects. Such would certainly have been the advice of her favourite Potemkin, who longed to lead a Russian army into France, even before the murder of the un-fortunate Louis. That general, however, had died in October 1791; and when Britain, Austria, and Prusfia, were leagued against the new republic, Catharine looked coolly on, in hopes, it is probable, of availing herself of their weakness, when exhausted by a long and bloody war. She gave refuge, indeed, in her dominions to many emigrants from France, and fent a squadron of ships to co-operate with the navy of England: but in this last measure she regarded merely her own immediate interest; for her crazy ships were repaired by British carpenters at the expence of the British government, and her officers had an opportunity of learning the evolutions of the British navy. She had likewise other prospects in view when she lent to the allies this flender aid. She meditated a new war with Turkey; and, depending upon meeting with no opposition, if she should not receive assistance from England and Austria, she slattered herself with accomplishing her flant? darling project of driving the Ottomans out of Europe, and of reigning in Constantinople. But she was difappointed. On the morning of the 9th of November 1796, she was seized with what her principal physician judged a fit of apoplexy; and, at 10 o'clock in the evening of the following day, expired, in the 68th year of her age, leaving behind her the character of one of the greatest sovereigns that ever swayed a sceptre.

After this long detail of the incidents of her life, it is needless to inform the reader that Catharine II. had no religion, and, of course, no principles of morality, which could induce her in every instance to do to others as she would have them do to her. She was a professed disciple of the French philosophers; by some of whom fhe was ridiculed, and by others cheated. The incense which she paid to the genius of Voltaire did not hinder him from frequently breaking his jests upon the autocratrix of Ruffia and her fucceffive favourites; and Didorot, whom she caressed, fold to her an immense library, when he possessed hardly a book, and was obliged to ranfack Germany and France for volumes to enable him to fulfil his bargain. Such is the friendship, and fuch the gratitude, which fubfifts among the amiable pupils of nature, and the philanthropic advocates

for the rights of man.

CAUDA Capricorni, a fixed flar of the fourth magnitude, in the tail of Capricorn; called also, by the Arabs, Dineb Algedi; and v by Bayer.

CAUDA Ceti, a fixed star of the third magnitude; called also, by the Arabs, Dineb Kaetos; marked & by

CAUDA Cygni, a fixed flar of the fecond magnitude, in the Swan's-tail; called by the Arabs Dineb Adigege, or Eldegiagich; and marked a by Bayer.

CAUDA Delphini, a fixed flar of the third magnitude, in the tail of the Dolphin; marked by Bayer.

CAUDA Dracquis, or Dragon's tail, the moon's fouth-

ern or descending node.

CAUDA Leonis, a fixed flar of the first magnitude, in the Lion's tail; called also, by the Arabs, Dineb Eleced; and marked B by Bayer. It is called also Lucida Cauda.

CAUDA Urfa Minoris, a fixed flar of the third magnitude, at the end of the Leffer Bear's tail; called also the Pole Star, and, by the Arabs, Alrukabah; and

marked a by Bayer.

CAUSE has been defined, we think, with accuracy in the Encyclopædia, and the doctrine stated which we believe to be true. Objections however have been made to that doctrine, of which we have endeavoured to remove fome, under the title Action, in this Supplement; and the dostrine itself has been well illustrated (at least fuch is our opinion) in the supplementary article Astronomy. We have, therefore, very little to add here on the subject of causes, though it is the most important subject which can employ the mind of man. What is the relation between a physical cause and that which is termed its effect-between heat, for instance, and the fusion of metals? Is it a necessary connection, or only a conjunction, discovered by experience to be con-

If by necessary connection be meant that kind of connection of which the contrary cannot be conceived, we do not think that the connection of any physical cause with its effect can be called necessary. We see no difficulty in conceiving, that fire, instead of fusing gold, might fix mercury. This may indeed be impossible; and we might perhaps fee the impossibility, did we as completely know the nature of fire and of metals as we know the relations of pure geometry. We know that the three angles of a plain triangle cannot possibly be either greater or less than two right angles; for in this comparison nothing is hid from our mental view. We do not, however, perceive the impossibility of mercury being fixed, as clay is hardened, by heat; for of heat, and mercury, and clay, we know very little, and

that little is the offspring of experience.

But if the connection between cause and effect be not necessary, are we not deprived of the means of demonstrating the great fundamental truth of religion? We have nowhere faid, that the connection between cause and effect is not necessary; but only, that we do not perceive the necessary connection between what are called physical causes and their effects. That every event is, and must be, brought about by fome cause, or some agency, we hold to be a self-evident truth, which no man can deny who understands the terms in which it is expressed; but what or where the agency is, we can very feldom, if ever, know, except when we think of our own voluntary actions. When a change is obferved, we cannot doubt of its being produced by something: either the thing changed is animated and has produced the change by its own agency, just as we move our heads and legs by an act of volition; or if it be inanimated, and of itself incapable of agency. the change has been produced by fomething external, denominated a cause. But all external causes, which are not likewise agents, in the proper fense of the word, may be traced, we think, as effects up to some agency; and therefore, in our opinion, there is no real, ultimate, efficient, cause but mind, or that which is endued with power. In proof of this doctrine, if it need any proof, we can only refer to what has been faid elsewhere on our no(ter. tions of power and of physical causes. See (Encycl.) METAPHYSICS, no 100, &c .- PHILOSOPHY and PHYsics paffim -- and (Suppl.) Action and Astronomy.

CENTER, or CENTRE, a word borrowed from the French name ceintre or cintre, given to the frame of timber by which the brick or stone of arched vaulting is supported during its erection, and from which it re-

ceives its form and curvature.

Pr ofe of

It is not our intention to describe the variety of conth rticle fructions which may be adopted in easy fituations, where the arches are of fmall extent, and where fufficient foundation can be had in every part of it for fupporting the frame. In fuch cases, the frequency of the props which we can fet up dispenses with much care; and a frame of very flight timbers, connected together in an ordinary way, will suffice for carrying the weight, and for keeping it in exact shape. But, when the arches have a wide ipan, and consequently a very great weight, and when we cannot fet up intermediate pillars, either for want of a foundation in the foft bottom of a river, or because the arch is turned between two lofty piers, as in the dome of a stately cathedral—we are then obliged to rest every thing on the piers themselves; and the framing which is to support our arch before the keystone is iet, must itself be an arch, depending on the mutual abutment of its beams. One should think that this view of the contruction of a centre would offer it felf at the first, naturally derived from the erection it was to affift: but it has not been fo. When intermediate pillars were not employed, it was usual to frame the mould for the arch with little attention to any thing but its shape, and then to cross it and recross it in all directions with other pieces of timber, till it was thought fo bound together that it could be lifted in any position, and, when loaded with any weight, could not change its shape. The frame was then raised in a lump, like any folid body of the same shape, and set in its place. This is the way still practifed by many country artists, who, having no clear principles to guide them, do not stop till they have made a load of timber almost equal to the weight which it is to carry.

But this artless method, besides leading the employer into great expence, is frequently fatal to the undertaker, from the unskilfulness of the construction. beams which connect its extremities are made also to fupport the middle by means of posts which rest on them. They are therefore exposed to a transverse or cross strain, which they are not able to bear. Their number must therefore be increased, and this increases the load. Some of these cross strains are derived from beams which are preffed very obliquely, and therefore exert a prodigious thrust on their supports. The beams are also greatly weakened by the mortises which are cut in them to receive the tenons of the croffing beams: and thus the whole is exceedingly weak, in proportion to what the same quantity of timber may be made by

a proper disposition of its parts.

The principles from which we are to derive this difposition are the general mechanical principles of carf conftric-pentry, of which we have given some account in that article. These furnish one general rule: When we would give the utmost strength possible to a frame of carpentry, every piece should be so disposed that it is subject to no strain but what either pushes or draws it in the direction of its length: and, if we would be in-

debted to timber alone for the force or firength of the Center, centre, we must rest all on the first of these strains; for when the straining force tends to draw a beam out of its place, it must be held there by a mortise and tenon, which possesses but a very trisling force, or by iron straps and bolts. Cases occur where it may be very difficult to make every frain a thrult, and the best artits admit of ties; and indeed where we can admit a tiebeam connecting the two feet of our frame, we need feek no better lecurity. But this may fometimes be very inconvenient. When it is the arch of a bridge that we are to support, such a tie-beam would totally ftop the passage of small craft up and down the river. It would often be in the water, and thus exposed to the most fatal accidents by freshes, &c. Interrupted ties, therefore, must be employed, whose joint or meetings must be supported by something analogous to the king-posts of roofs. When this is judiciously done, the fecurity is abundantly good. But great judgment is neceffary, and a very lerupulous attention to the disposition of the pieces. It is by no means an easy matter to discern whether a beam, which makes a part of our centre, is in a state of compression or in a state of extenfion. In some works of the most eminent carpenters even of this day, we fee pieces confidered as struts (and considerable dependence had on them in this capacity), while they are certainly performing the office of tie-beams, and should be secured accordingly. This was the case in the boldest centre (we think) that has been executed in Europe, that of the bridge of Orleans, by Mr Hupeau. Yet it is evidently of great confequence not to be mistaken in this point; for when we are mistaken, and the piece is stretched which we imagine to be compressed, we not only are deprived of some support that we expected, but the expected support has become an additional load.

To ascertain this point, we may suppose the piers How to difto yield a little to the preffure of the archftones on the tinguish a centre frames. The feet, therefore, fly outwards, and frut from a the shape is altered by the finking of the crown. We tic. must draw our frame anew for this new state of things, and must notice what pieces must be made longer than before. All fuch pieces have been acting the part of

tie-beams.

But a centre has still another office to sustain; it must keep the arch in its form; that is, while the load on the centre is continually increasing, as the masons lay on more courses of arch stones, the frame must not yield and go out of shape, finking under the weight on the haunches, and rifing in the crown, which is not yet carrying any load. The frame must not be supple; and must derive its stiffness, not from the closeness and ftrength of its joints, which are quite infignificant when fet in competition with fuch immense strains, but from ftruts or ties, properly disposed, which hinder any of the angles from changing its amplitude.

It is obvious, from all that has been faid, that the How to festrength and stiffness of the whole must be found in the cure stifftriangles into which this frame of carpentry may be renefs and folved. We have feen that the firains which one piece frength. produces on two others, with which it meets in one point, depends on the angles of their interfection; and that it is greater as an obtuse angle is more obtuse, or an acute angle more acute. And this fuggests to us the general maxim, "to avoid as much as possible all

eneral rinciples

ceffarily accompanied by obtuse ones, are not so hurtful; because the strain here can never exceed the straining force; whereas, in the case of an obtuse angle, it may

. furpass it in any degree.

Such are the general rules on this subject. Although fomething of the mutual abutment of timbers, and the fupport derived from it, has been long perceived, and employed by the carpenters in roofing, and also (doubtless) in the forming of centres, yet it is a matter of hittorical fact, that no general and distinct views had been taken of it till about the beginning of this century, or a little earlier. Fontana has preserved the figure of the frames on which the arches of St Peter's at Rome were turned. The one employed for the dome is constructed with very little skill; and those for the arches of the nave and transepts, though incomparably superior, and of confiderable simplicity and strength, are yet far inferior to others which have been employed in later times. It is much to be regretted that no trace remains of the forms employed by the great architect and confummate mechanician Sir Christopher Wren. We should doubtless have seen in them every thing that science and great fagacity could fuggest. We are told, indeed, that his centering for the dome of St Paul's was a wonder of its kind; begun in the air at the height of 160 feet from the ground, and without making use of even a projecting corniche whereon to rest it.

The earliest theory of the kind that we have met The earliest theory, on with, that is proposed on scientific principles, and with the express purpose of serving as a lesson, are two cenprinciples, tres by Mr Pitot of the Academy of Sciences, about the beginning of this century. As they have confiderable merit (greatly refembling those employed by Michael Angelo in the nave of St Peter's), and afford some good maxims, we shall give a short account of them. We crave the excuse of the artists if we should employ their terms of art somewhat aukwardly, not being very familiarly acquainted with them. Indeed, we observe very great differences, and even ambiguity, in the terms em-

ployed ..

What we shall describe under the name of a centre is (properly speaking) only one frame, truss, or rib, of a centre. They are set up in vertical planes, parallel to the truffes or main couples of a roof. Bridging joilts are laid across them .- In smaller works these are laid sparingly, but of confiderable scantling, and are boarded over; but for great arches, a bridging joist is laid for every course of archstones, with blockings between to keep them at their proper distances. The stones are not laid immediately on these joists, but beams of soft wood are laid along each joift, on which the stone is laid. These beams are afterwards cut out with the chiffel, in order to separate the centre from the ring of stones, which must now support each other by their mutual abutment.

Muftrated

The centre is distinguishable into two parts, ALLB Plate XIV (fig. 1.) and LDL, which are pretty independent of each other, or at least act separately. The horizontal STRETCHER LL cuts the semicircle ADB half way between the spring and the crown of the arch; the arches AL, LD, being 45° each. This stretcher is divided in the same proportion in the points G and H; that is, tGH is one half of LL, and LG, HL are each one-

Center. very obtule angles." Acute angles, which are not ne- fourth of LL nearly. Each end is supported by two Center STRUTS EI, GI, which rest below on a Sole or BED properly supported. The interval between the heads of the struts GI, HK is filled up by the STRAINING BEAM GH. abutting in a proper manner on the struts (see CARPENTRY, Supplement). The extremities I., L, are united in like manner by butting joints, with the heads of the outer struts. The ARCH MOULDS AP, BP, are connected with the struts by cross pieces PQ, which we finall call BRIDLES, which come inwards on each fide of the struts (being double), and are bolted to them. This may be called the lower part of the frame. The upper part confilts of the king post DR, supported on each side by the two struts or braces ML, ON, mortised into the post, and also mortised into the stretcher, at the points L, N, where it is supported by the struts below. The arches LD, LD are connected with the struts by the bridles PQ, in the same manner as below.

There is a great propriety in many parts of this ar-Propriety rangement. The lower parts or haunches of the archof this ar press very lightly on the centres. Each architone is ly-rangemen ing on an inclined plane, and tends to slide down only with its relative weight; that is, its weight is to its tendency to slide down the joint as radius to the fine of elevation of the joint. Now it is only by this tendency to slide down the joint that they press on the centering, which in every part of the arch is perpendicular to the joint: But the pressure on the joint, arising from this cause, is much less than this, by reason of the friction of the joints. A block of dry freestone will not slide down at all; and therefore will not press on the centering, if the joint be not elevated 35 degrees at least. But the archstones are not laid in this manner, by sliding them down along the joint, but are laid on the centres, and flide down their flope, till they touch the blocks on which they are to rest; so that, in laying the archstones, we are by no means allowed to make the great deduction from their weight just now mentioned, and which Mr Couplet prescribes (Mem. Acad. Sciences, 1729). But there is another cause which diminishes the pressure on the centres; each block slides down the planks on which it is laid, and preffes on the block below it, in the direction of the tangent to the arch. This pressure is transmitted through this block, in the same each other, at the diffance of 5, 6, 7, or 8 feet, like direction, to the next, and through it to the third, &c. In this manner it is plain that, as the arch advances, there is a tangential pressure on the lower archstones, which diminishes their pressure on the frame, and, if fufficiently great, might even push them away from it. Mr Couplet has given an analysis of this pressure, and shews, that in a semicircular arch of uniform thickness none of the arch flones below 30° press on the frames. But he (without faying fo) calculates on the supposition that the blocks descend along the circumference of this frame in the same manner as if it were perfectly smooth. As this is far from being the case, and as the obstructions are to the last degree various and irregular, it is quite useless to institute any calculation on the subject. A little reflection will convince the reader, that in this case the obstruction arising from friction must be taken into account, and that it must not be taken into account in estimating the pressure of each successive course of stones as they are laid. It is enough that we fee that the pressure of the lower courses of architones on the frame is diminished. Mr Couplet says, that the

c et whole preffure of a femicircular arch is but this of its weight; but it is much greater, for the reason just now given. We have tried, with a well made wooden model (of which the circumference was rubbed with black entrelead to render it more slippery), whether any part of the of l Fi- wooden blocks representing the archstones were detached from the frame by the tangential pressure of the superior blocks; but we could not fay confidently that any were so detached. We perceived that all kept hold of a thin flip of Chinese paper (also rubbed with black lead) between them and the frame, fo that a fensible force was required to pull it out. From a combination of circumstances, which would be tedious to relate, we believe that the centres carry more than two-thirds of the weight of the arch before the keystone is set. In elliptical and lower pitched circular arches, the proportion is still greater.

It feems reasonable enough, therefore, to dispose the framing in the manner proposed by Pitot, directing the main support to the upper mass of the arch, which presses most on the frame. We shall derive another advantage from this construction, which has not occurred

to Mr l'itot.

There is an evident propriety in the manner in which he has distributed the supports of the upper part. The ftruts which carry the king post spring from those points of the stretcher where it rests on the struts below: thus the stretcher, on which all depends, bears no transverse strains. It is stretched by the strut above it, and it is compressed in a small degree between the struts below it, at least by the outer ones. Mr Pitot proposes the straining beam GH as a lateral support to the stretcher, which may therefore be of two pieces: but although it does an yment its strength, it does not feem necessary for it. The stretcher is abundantly carried by the strap, which may and should suspend it from the king post. great use of the straining piece is to give a firm abutment to the inner struts, without allowing any lateral strain on the stretcher. N. B. Great care must be taken to make the hold fufficiently firm and extensive between the stretcher and the upper struts, fo that its cohesion to resist the thrusts from these struts may be much employed.

The only imperfection that we find in this frame is the lateral strains which are brought upon the upper firuts by the bridles, which certainly transmit to them part of the weight of the archftones on the curves. The space between the curves and ML should also have been truffed. Mr Pitot's form is, however, extremely ftiff; and the caufing the middle bridle to reach down to the firetcher, feems to fecure the upper firuts from

all risk of bending.

This centre gives a very distinct view of the offices of all the parts, and makes therefore a proper introduction to the general subject. It is the simplest that can be in its principle, because all the effential parts are subjected to one kind of ftrain. The stretcher LL is the only exception, and its extension is rather a collateral circumstance than a step in the general support.

The examination of the strength of the frame is exength of tremely easy. Mr Pitot gives it for an arch of 60 feet is frame span, and supposes the architones 7 feet long, which is a monstrous thickness for so small an arch; 4 feet is an abundant allowance, but we shall abide by his construction. He gives the following scantlings of the parts:

SUPPL. VOL. I. Part I.

The ring or circumference confifts of pieces of cak Center. 12 inches broad and 6 thick.

The stretcher LL is 12 inches square. The straining piece GH is also 12 by 12.

The lower struts 10 by 8. The king post 12 by 12. The upper struts 10 by 6. The bridles 20 by 8.

These dimensions are French, which is about Tth larger than ours, and the superficial dimensions (by which the fection and the absolute strength is measured) is almost the larger than ours. The cubic foot, by which the stones are measured, exceeds ours nearly th. The pound is deficient about "the. But fince very nice calculation is neither easy nor necessary on this subject, it is needless to depart from the French measures, which would occasion many fractional parts and a troublesome reduction.

The arch is supposed to be built of stone which weighed 160 pounds per foot. Mr Pitot, by a computation (in which he has committed a mistake), says, that only Tiths of this weight is carried by the frame. We believe, however, that this is nearer the truth than Mr Couplet's affumption of 4ths already mentioned.

Mr Pitot farther assumes, that a square inch of sound oak will carry 8640 pounds. By his language we should imagine that it will not carry much more: but this is very far below the strength of any British oak that we have tried; fo far, indeed, that we rather imagine that he means that this load may be laid on it with perfect fecurity for any time. But to compensate for knots and other accidental imperfections, he affumes 7200 as the measure of its absolute force.

He computes the load on each frame to be 707520 pounds, which he reduces to taths, or 555908 pounds.

The absolute force of each of the lower struts is 576000 (at 7200 per inch), and that of the curves 518400. Mr Pitot, confidering that the curves are kept from bending outwards by the arch stones which press on them, thinks that they may be considered as acting precisely as the outer struts EI. We have no objection to this supposition.

With these data we may compute the load which the Computed. lower truss can safely bear by the rule delivered in the article CARPENTRY. We therefore proceed as fol-

Measure off by a scale of equal parts as, at, each 576000, and add to 518400. Complete the parallelogram avxs, and draw the vertical xc, meeting the horizontal line aC in c. Make c b equal to ca. Join x b, and complete the parallelogram a x b y. It is evident that the diagonal x y will represent the load which these pieces can carry; for the line a v is the united force of the curve AP and the strut IE, and as is the strength of IG. These two are equivalent to ax. xb is, in like manner, equivalent to the support on the other fide, and xy is the load which will just balance the two supports a x and b x.

When xy is measured on the same scale, it will be found = 2850000 pounds. This is more than five times the load which actually lies on the frame. It is therefore vaftly stronger than is necessary. Half of each of the linear dimensions would have been quite sufficient, and the struts needed only to be 5 inches by 4. Even this would have carried twice the weight, and

Bb

would

Center. would have borne the load really laid on it with perfect

We proceed to measure the strength of the upper part. The force of each strut is 432000, and that of the curve is 518400; therefore, having drawn M v parallel to the ftrut ON, make Mv = 432000, and Ms= 432000 + 518400. Complete the parallelogram Msrv. Draw the horizontal line rk, cutting the vertical MC in k, and make ky = Mk. It is plain, from what was done for the lower part, that My will measure the load which can be carried by the upper part. This will be found = 1160000. This is also greatly superrior to the load; but not in fo great a proportion as the other part. The chief part of the load lies on the upper part; but the chief reason of the difference is the greater obliquity of the upper struts. This shortens the diagonal My of the parallelogram of forces. Mr Pitot should have adverted to this; and instead of making the upper struts more slender than the lower, he should have made them stouter.

The strain on the stretcher LL is not calculated. It is measured by r'k, when My is the load actually lying on the upper part. Less than the fixth part of the cohefion of the stretcher is more than sufficient for the horizontal thruft; and there is no difficulty of making the foot joints of the struts abundantly strong for the pur-

pose.

The reader will perceive that the computation just now given does not state the proportions of the strains actually exerted on the different pieces, but the load on the whole, on the supposition that each piece is subjected to a strain proportioned to its strength. The other calculation is much more complicated, but is not neces-

This centre has a very palpable defect. If the piers should yield to the load, and the feet of the centre fly out, the lower part will exert a very confiderable frain on the fretcher, tending to break it across between N and L, and on the other fide HKF of the lower part is firmly bound together, and cannot change its shape, and will therefore act like a lever, turning round the point F. It will draw the strut HK away from its abutment with GH, and the stretcher will be strained across at the place between H and F, where it is bolted with the bridle. This may be refifted in some degree by an iron frap uniting ON and HK; but there will still be a want of proportional strength. Indeed, in an arch of such height (a semicircle), there is but little risk of this yielding of the piers; but it is an imperfection.

A centre

The centre (fig. 2) is constructed on the same prinon the same ciple precisely for an elliptical arch (A). The calculaprinciples tion of its flrength is nearly the same also; only the for an ellip-two upper firsts of a fide being parallel, the parallelogram Morv (of fig. 1) is not needed, and in its flead we measure off on ON a line to represent twice its firength. This comes in place of Mr' of fig 1.- N. B. The calculation proceeds on the supposition that the

fume) to separate the heads of the struts, that their ob. Center, liquity might be leffened thereby: and this is a good thought; for when the angle formed by the struts on each fide is very open, the strain on them becomes very

The stretcher of this frame is fearfed in the middle. Suppose this joint to yield a little, there is a danger of the lower strut ON losing its hold, and ceasing to join in the support; for when the crown finks by the lengthening of the stretcher, the triangle ORN of fig. 2. will be more distorted than the space above it, and ON will be loofened. But this will not be the case when the finking of the crown arises from the mere compression of the struts. Nor will it happen at all in the centre, fig. 1. On the contrary, the strut ON will abut more firmly by the yielding of the foot of

The figure of this arch of Mr Pitot's confifts of three arches of circles, each of 60 degrees. As it is elegant, it will not be unacceptable to the artist to have a construction for this purpose.

Make BY = CD, and $\overrightarrow{CZ} = \frac{1}{2}$ CY. Describe the How to femicircle ZÆY, and make ZS = ZÆ. S is the centre confinua of the fide arches, each of 60 degrees. The centre T of fuch an the arch, which unites these two, is at the angle of an arch.

equilateral triangle STS

This conftruction of Mr Pitot's makes a handsome oval, and very near an ellipfis, but lies a little without We shall add another of our own, which coincides with the ellipse in eight points, and furnishes the artist, by the way, a rule for drawing an infinite variety of

Let AB, DE (fig. 2. No 2.) be the axes of an ellipse, C the centre, and F, f the two foci. Make C & = CD, and describe a circle AD be passing through the three given points A, D, and b. It may be demonstrated, that if from any point P of the arch AD be drawn a chord PD, and if a line PRr be drawn. making the angle DPR = PDC, and meeting the two axes in the points R and r, then R and r will be the centres of circles, which will form a quarter APD of an oval, which has AB and DE for its two axes.

We want an oval which shall coincide as much as poffible with an ellipfis? The most likely method for this is to find the very point P where the ellipfis cuts the circle AD be. The easiest way for the artist is to defcribe an arch of a circle a m, having AB for its radius, and the remote focus f for its centre. Then fet one foot of the compasses on any point P, and try whether the distance PF from the nearest focus F is exactly equal to its distance Pm from that circle. Shifting the foot of the compasses from one point of the arch to another, will foon discover the point. This being found, draw PD, make the angle DPr = PDr, and R and r are the centres wanted. Then make Cs = CR, and we get the centres for the other fide.

The geometer will not relish this mechanical construction. He may therefore proceed as follows: Draw fhort straining piece MM makes but one firm body with Dd parallel to AB, cutting the circle in d. Draw ed the king post. Mr Pitot employed this piece (we pre- cutting AC in N. Draw CG parallel to Ae, and make

⁽A) It is the middle arch of the bridge at Lille Adam, of which Mr Pitot had the direction. It is of 80 feet span, and rises 31 feet.

Oi. Make OM, OM' = Oi, and draw MP, M'P' perpendicular to AB. These ordinates will cut the circle All be in the points P and P', where it is cut by the ellipse. We leave the demonstration as a geometrical exercise for the dilettante.

We faid, that this centering of Mr Pitot's refembled he ve of in principle the one employed by Michael Angelo for er's the nave and transepts of St Peter's church at Rome. Fontana, who has preferved this, ascribes the construction of it to one of the name of San Gallo. A sketch of it is given in fig. 3. It is, however, fo much superior, and fo different in principle, from that employed for the cupola, that we cannot think it the invention of the same person. It is, like Pitot's, not only divisible, but really divided into two parts, of which the upper carries by much the greatest part of the load. The pieces are judiciously disposed, and every important beam is amply fecured against all transverse strains. Its only fault is a great profusion of strength. The innermost polygon aghb is quite superfluous, because no strain can force in the struts which rest on the angles. Should the piers yield outwards, this polygon will be loofe, and can do no service. Nor is the triangle gib of any use, if the king post above it be strapped to the tie-beam and firaining fill. Perhaps the inventor confidered the king post as a pillar, and wished to secure the tie-beam against its cross strain. This centering, however, must be allowed to be very well composed; and we expect that the well-informed reader will join us in preferring it to Mr Pitot's, both for fimplicity of principle, for scientific propriety, and for strength.

There is one confiderable advantage which may be derived from the actual division of the truss into two parts. If the tie-beam LL, instead of resting on the firetcher EF, had rested on a row of chocks formed like double wedges, placed above each other, head to point, the upper part of the centering might be fruck independent of the lower, and this might be done gradually, beginning at the outer ends of the firetcher. By this procedure, the joints of the architones will close on the haunches, and will almost relieve the lower centering, fo that all can be pulled out together. Thus may the arch fettle and confolidate in perfect fafety, without any chance of breaking the bond of the mortar in any part; an accident which frequently happens in great arches. This procedure is peculiarly advisable for low pitched or elliptical arches. But this will be more clearly seen afterwards, when we treat of the internal movements of an arch of masonry.

This may fuffice for an account of the more simple construction of truffed centres; and we proceed to such as have a much greater complication of principle. We shall take for examples some constructed by Mr Personet, a very celebrated French architect

Mr Perronet's general maxim of construction is to make the truss consist of several courses of separate trusles, independent (as he thinks) of each other, and thus to employ the joint support of them all. In this confruction it is not intended to make use of one truss, or part of one trufs, to support another, as in the former fet, and as is practifed in the roofs of St Paul's church, Covent Garden, and in Drury Lane theatre. Each truls spans over the whole distance of the piers, and would stand alone (having, however, a tottering equili-

('er. the angle CG i = AD e. Bisect CN in O, and join brium.). It consists of a number of struts, set end to Center. end, and forming a polygon. These trusses are so arranged, that the angles of one are in the middle of the fides of the next, as when a polygon is inferibed in a circle, and another (of the fame number of fides) is circumferibed by lines which touch the circle in the angles of the inferibed polygon. By this construction the angles of the alternate truffes he in lines pointing towards the centre of the curve. King posts are therefore placed in this direction between the adjoining beams of the truffes. These king posts confist of two beams, one on each fide of the truls, and embrace the trulsbeams between them, meeting in the middle of their thickness. The abutting beams are mortised, half into each half of the post. The other beam, which makes the base of the triangle. passes through the post, and a ftrong bolt is driven through the joint, and fecured by a key or a nut. In this manner is the whole united; and it is expected, that when the load is laid on the uppermost truss, it will all butt together, forcing down the king posts, and therefore prefing them on the beams of all the inferior truffes, caufing them also to abutt on each other, and thus bear a share of the load. Mr Perrouet does not assume the invention to himself; but says, that it was invented and practised by Mr Mansard de Sagonne at the great bridge of Moulins. It is much more ancient, and is the work of the celebrated physician and architect Perrault; as may be feen in the collection of machines and inventions of that gentleman published after his death, and also in the great collection of inventions approved of by the Academy of Sciences. It is this which we propose to examine.

Fig 4. represents the centering employed for the Centering bridge of Cravant. The arches are elliptical, of 60 seet employed fpan and 20 feet rife. The architones are four feet for the thick, and weigh 176 pounds per foot. The truss- Cravant, beams were from 15 to 18 feet long, and their fection was 9 inches by 8. Each half of the king posts was about 7 feet long, and its fection 9 inches by 8. The whole was of oak. The five truffes were 51 feet asunder. The whole weight of the arch was 1350000 lbs. which we may call 600 tons (it is 558). This is about 112 tons for each truss. We must allow near 90 tons of this really to press the trus. A great part of this pressure is borne by the four beams which make the feet of the trufs, coupled in pairs on each fide. The diagonal of the parallelogram of forces drawn for these beams is, to one of the fides, in the proportion of 360 to 285. Therefore say, as 360 to 285; so is 90 to 71½ tons, the thrust on each foot. The section of each is 144 inches. We may with the utmost safety lay three tons on every inch for ever. This amounts to 432 tons, which is more than fix times the strain really pressing the foot beams in the direction of their length; nay, the upper truss alone is able to carry much more than its load. The absolute strength of its foot-beam is 216 tons. It is much more advantageously placed; for the diagonal of the parallelogramof forces corresponding to its pontion is to the fide as 438 to 285. This gives 58 to tons for the strain on each foot; which is not much above the tourth part of what it is able to carry for ever. No doubt can therefore be entertained of the superabundant strength of this centering. We fee that the upper row of ftruts is cuite sufficient, and all that is wanted is to procure fliffnels for it; for it mud be carefully kept in mind, that B b 2

15 'erronet's naxim of onstrucion.

Center. that this upper row is not like an equilibrated arch. It, fore a crofs strain on the beams. Observe also, that the Center. the joints at the crown raised up. This must be refisted.

Here then we may gather, by the way, a useful lesson. Let the outer row of struts be appropriated to the carriage of the load, and let the rest be employed for giving stiffness. For this purpose let the outer row have abundant strength. The advantages of this method are considerable. The position of the beams of the exterior row is more advantageous, when (as in this example) the whole is made to rest on a narrow foot: for this obliges us to make the latt angle, at least of the lower row, more open, which increases the strain on the strut; besides, it is next to impossible to distribute the compressing thrusts among the different rows of the truss beams; and a beam which, during one period of the mason work, is acting the part of a strut, in another period is bearing no strain but its own weight, and in another it is stretched as a tie. A third advantage is, that, in a case like this, where all rests on a narrow foot, and the lower row of beams are bearing a great part of the thrust, the horizontal thrust on the pier is very great, and may push it aside. This is the most ruinous accident that can happen. An inch or two of yielding will cause the crown of the arch to fink prodigiously, and will instantly derange all the bearings of the abutting beams: but when the lower beams already act as ties, and are quite adequate to their office, we render the frame perfectly stiff or unchangeable in its form, and take away the horizontal thrust from the piers entirely. This advantage is the more valuable, because the very circumstance which obliges us to rest all on a narrow foot, places this foot on the very top of the pier, and makes the horizontal thrust the more dangerous.

But, to proceed in our examination of the centering of Cravant bridge, let us suppose, that the king posts are removed, and that the beams are joined by compass joints. If the pier shall yield in the smallest degree, both rows of struts must fink; and fince the angles (at least the outermost) of the lower row are more open than those of the upper row, the crown of the lower

row will fink more than that of the upper.

The angles of the alternate rows must therefore separate a little. Now restore the king posts; they prevent this separation. Therefore they are stretched; therefore the beams of the lower row are also stretched: consequently they no longer butt on their mortises, and must be held in their places by bolts. Thus it appears that, in this kind of fagging, the original distribution of the load among the different rows of beams is changed, and the upper row becomes loaded beyond our expecta-

If the fagging of the whole truss proceed only from the compression of the timbers, the case is different, and we may preserve the original distribution of mutual abutment more accurately. But in this case the stiffness of the frame arises chiefly from cross strains. Suppose that the frame is loaded with architones on each fide up to the posts HC, hc; the angles E and e are pressed down, and the beams EOF, eoF push up the point F. This cannot rife without bending the beams EOF, eoF; because O and o are held down by the double king posts, which grasp the beams between them. There is there-

will be very unequally loaded as the work advances. triangle EHF does not preferve its shape by the con-The haunches of the frame will be pressed down, and nection of its joints; for although the strut beams are mortifed into the king post, they are in very shallow mortifes, rather for steadying them than for holding them together. Mr Perronet did not even pin them, thinking that their abutment was very great. The triangle is kept in shape by the base EF, which is firmly bolted into the middle post at O. Had these intersections not been strongly bolted, we imagine that the centres of some of Mr Perronet's bridges would have yielded much more than they did; yet some of them yield. ed to a degree that our artists would have thought very dangerous Mr Perronet was obliged to load the crown of the centering with very great weights, increasing them as the work advanced, to prevent the frames from going out of shape: in one arch of 120 feet he laid on 45 tons. Not withstanding this imperfection, which is perhaps unavoidable, this mode of framing is undoubtedly very judicious, and perhaps the best which can be employed without depending on iron work.

Fig. 5. represents another, constructed by Perronet For the for an arch of 90 feet span and 28 feet rife. The trus-bridge of fes were 7 feet apart, and the arch was 41 thick; so that Nogent, the unreduced load on each frame was very nearly 235 tons. The scantling of the struts was 15 by 12 inches. The principle is the same as that of the former. The chief difference is, that in this centre the outer trussbeam of the lower row is not coupled with the middle row, but kept nearly parallel to the outer beam of the upper row. This adds greatly to the strength of the foot, and takes off much of the horizontal thrust from

Mr Perronet has shewn great judgment in causing the polygon of the inner row of trufs beams gradually to approach the polygon of the outer row. By this disposition, the angles of the inner polygon are more acute than those of the outer. A little attention will shew, that the general fagging of all the polygons will keep the abutments of the lower one nearer, or exacily, to their original quantity. We must indeed except the foot-beam. It is still too oblique; and, instead of converging to the foot of the upper row, it should have diverged from it. Had this been done, this centre is almost perfect in its kind. As it is, it is at least fix times stronger than was absolutely necessary. We shall have occasion to refer to this figure on another occasion.

This maxim is better exemplified by Mr Perronet in St Maxthe centering of the bridge of St Maxence, exhibited in ence, fig. 5. no 2. than in that of Nogent, fig. 5. no 1. But we think that a horizontal truss-beam a b should have been inserted (in a subordinate manner) between the king posts next the crown on each side. This would prevent the crown from rifing while the haunches only are loaded, without impairing the fine abutments of cd, cd, when the arch is nearly completed. This is an excellent centering, but is not likely to be of much use in thefe kingdoms; because the arch itself will be cousidered as ungraceful and ugly, looking like a huge lintel. Perronet says, that he preferred it to the ellipse, because it was lighter on the piers, which were thin. But the failure of one arch must be immediately followed by the ruin of all We know much better methods of lightening the piers.

Fig. 6. represents the centering of the bridge of

Neuilly,

120 feet span, and 30 feet rise, and is 5 feet thick. The frames are 6 feet apart, and each carries an absolute (that is, not reduced to 11 or to 4) load of 350 tons. The first beams are 17 by 14 inches in fcant-ling. The king posts are of 15 by 9 each half; and the horizontal bridles, which bind the different frames together in five places, are also 15 by 9 each half. There are eight other horizontal binders of 9 inches

This is one of the most remarkable arches in the world; not altogether on account of its width (for there are several much wider), but for the flatness at the crown; for about 26 feet on each fide of the middle it was intended to be a portion of a circle of 150 feet radius. An arch (femicircular) of 300 feet span might therefore be easily conftructed, and would be much stronger than this, because its horizontal thrust at the crown would be vaftly greater, and would keep it more

firmly united.

The bolts of this centre are differently placed from those of the former; and the change is judicious. Mr Perronet had doubtless found by this time, that the stiffness of his framing depended on the transverse strength of the beams; and therefore he was careful not to weaken them by the bolts. But notwithstanding all his care, the framing funk upwards of 13 inches before the keystones were laid; and during the progress of the work, the crown rose and suck, by various steps, as the loading was extended along it. When 20 courses were laid on each fide, and about 16 tons laid on the crown of each frame, it funk about an inch. When 46 courles were laid, and the crown loaded with 50 tons, it funk about half an inch more. It continued finking as the work advanced; and when the keystone was set it had sunk 134 inches. But this finking was not general; on the contrary, the frame had rifen greatly at the very haunches, so as to open the upper part of the joints, many of which gaped an inch; and this opening of the joints gradually extended from the haunches towards the crown, in the neighbourhood of which they opened on the under fide. This evidently arose from a want of stiffness in the frame. But these joints closed again when the centres were struck, as will be mentioned af-

We have taken particular notice of the movements and twisting of this centre, because we think that they indicate a deficiency, not only of stiffness, but of abutment among the truss beams. The whole has been too flexible, because the angles are too obtuse: This arises from their multiplicity. When the intercepted arches have fo little curvature, the power of the load to press it inward increases very fast. When the intercepted arch is reduced to one half, this power is more than doubled; and it is also doubled when the radius of curvature is doubled. The king-posts should have been farther apart near the crown, fo that the quantity of arch between them should compensate for its diminished curvature.

The power of withstanding any given inequality of load would therefore have been greater, had the centre confifted of fewer pieces, and their angles of meeting been proportionally more acute. The greatest improvement would have been, to place the foot of the lower tier of truss-beams on the very foot of the pier, and to

er. Neuilly, near Paris, also by Perronet. The arch has have also separated it at the head from the rest with a Center. longer king-polt, and thus to have made the distances of the beams on the king posts increase gradually from the crown to the fpring. This would have made all the angles of abutment more acute, and would have produced a greater pressure on all the lower tiers when the frame fagged.

Fig. 7. represents the centering of the bridge of Or-Orleans, ins. I'he arch has 100 feet span, and rifes 30, and the arch-stones are 6 feet long, It is the construction of Mr Hupcau, the first architect of the bridge. It is the boldest work of the kind that we have seen, and is conttructed on clear principles. 'The main abutments are few in number. Because the beams of the outer polygon are long, they are very well supported by Araining beams in the middle; and the struts or braces which support and butt on them, are made to rest on points carried entirely by ties. The inventor, however, feems to have thought that the angles of the inner polygon were supported by mutual compression, as in the outer polygon. But it is plain that the whole inner polygon may be formed of iron rods. Not but that both polygons may be in a flate of compression (this is very possible); but the smallest sagging of the frame will change the proportions of the preffures at the angles of the two polygons. The pressures on the exterior angles will increase, and those on the lower or interior angles will diminish most rapidly; so that the abutments in the lower polygon will be next to nothing. Such points could bear very little pressure from the braces which support the middle of the long bearings of the upper beams, and their pressures must be borne chiefly by the joints supported by the king-posts. The king posts would then be in a state of extension. It is difficult, however, to decide what is the precise state of the pressure at these interior angles.

The hittory of the erection of this bridge will throw Inftructive much light on this point, and is very instructive. Mrhistory of Hupeau died before any of the arches were carried far- this centre. ther than a very few of the fuft courses. Mr Perronet fucceeded to the charge, and finished the bridge. As the work advanced, the crown of the frame rose very much. It was loaded; and it funk as remarkably.

This shewed that the lower polygon was giving very little aid. - Mr Perronet then thought the frame too weak, and inferted the long beam DE, making the diagonal of the quadrangle, and very nearly in the direction of the lower beam ab, but falling rather below this line. He now found the frame abundantly strong. It is evident that the truss is now changed exceedingly, and confifts of only the two long fides, and the fhort straining beam lying horizontally between their heads. The whole centering confifts now of one great truss a E e b, and its long fides a E, e b, are truffed up at B and f. Had this fimple idea been made the principle of the construction, it would have been excellent. The angle a DE might have been about 176°, and the polygon Deghemployed only for giving a flight support to this great angle, so as not to allow it to exceed 180°. But Mr Perronet found, that the joint c, at the foot of the post Ec, was about to draw loose, and he was obliged to bolt long pieces of timber on each fide of the joint, embracing both beams. These were evi-

dently acting the same part as iron straps would have

done; a complete proof that, whatever may have been

the point c, and that the beams that met there were not in a state of compression, but were on the stretch. Mr Perronet fays that he put these cheeks to the joints to sliffen them. But this was not their office; because the adjoining beams were not struts, but ties, as we have

now proved.

We may therefore conclude, that the outer polygon, with the assistance of the pieces a b, DE, were carrying the whole load. We do not know the distance between the frames; but supposing them seven feet apart, and the arch 6 feet thick, and weighing 170 pounds per foot, we learn the load. The beams were 16 inches square. If we now calculate what they would bear at the fame very moderate rate allowed to the other centres, we find that the beams AB and a b are not loaded to one-fixth

of their strength.

We have given this centre as a fine example of what carpentry is able to perform, and because, by its simplicity, it is a fort of text on which the intelligent artist may make many comments. We may see plainly that, if the lower polygon had been formed of iron rods, firmly bolted into the feet of the king-posts, it would have maintained its shape completely. The service done by the beam DE was not fo much an increase of abutment as a discharge of the weight and of the pull at the joint c. Therefore, in cases where the feet of the truss are necessarily confined to a very narrow space, we should be careful to make the upper polygon sufficient to carry the whole load (fay by doubling its beams), and we may then make the lower polygon of slender dimenfions, provided we fecure the joints on the king-pofts by iron straps which embrace a considerable portion of the tie on each fide of the joint.

We are far from thinking that these centres are of the best kind that could be employed in their fituation; but they are excellent in their kind; and a careful fludy of them will teach the artist much of his profession. When we have a clear conception of the state of strain in which the parts of a frame really are, we know what should be done in order to draw all the advantage possible from our materials. We have said in another place, that where we can give our joints sufficient connection (as by straps and bolts, or by cheeks or fishes), it is better to use ties than struts, because

ties never bend.

We do not approve of Mr Perronet's practice of giving his truffes such narrow feet. By bringing the foot of the lower polygon farther down, we greatly diminish all the strains, and throw more load on the lower polygon: and we do not fee any of Mr Perronet's centres where this might not have been done. He feems to affect a great span, to shew the wonders of his art; but our object is to teach how to make the best centre of a given quantity of materials; and how to make the most perfect centre, when we are not limited in this respect, nor in the extent of our fixed points.

We shall conclude this series of examples with one of the cen- where no fuch affectation takes place. This is the centre employ-tering of the bridge at Blackfriars, London. The span Blackfriars of the arch is 100 feet, and its height from the spring is about 43. The drawing fig. 8. is fufficiently minute to eonvey a distinct notion of the whole construction. We need not be very particular in our observations, after what has been faid on the general principles of con-

Center, the original preffures, there was no abutment now at firuction. The leading maxim, in the prefent example, Center, feems to be, that every part of the arch shall be supported by a simple truss of two legs resling, one on each pier. H, H, &c. are called APRON PIECES to firengthen the exterior joints, and to make the RING as stiff in itself as possible. From the ends of this apron-piece proceed the two legs of each trufs. Thele legs are 12 inches square: They are not of an entire piece, but of several, meeting in firm abutment Some of their meetings are fecured by the double king posts, which grasp them firmly between them, and are held together by bolts. At other intersections, the beams appear halved into each other; a practice which cannot but weaken them much, and would endanger their breaking by crofs ftrains, if it were possible for the frame to change its shape. But the great breadth of this frame is an effectual stop to any fuch change. The fact was, that no finking or twisting whatever was observed during the progress of the mason work. Three points in a straight line were marked on purpose for this observation, and were observed every day. The arch was more than fix feet thick; and yet the finking of the crown, before fetting the key-stones, did not amount to one inch.

The centre employs about one-third more timber than Perronet's great centre in proportion to the span of the arch; but the circumference increases in a greater proportion than this, because it is more elevated. In every way of making a comparison of the dimenfions, Mr Mylne's arch employs more timber; but it is beyond all comparison stronger. The great elevation is partly the reason of this. But the disposition of the timbers is also much more advantageous, and may be copied even in the low pitched arches of Neuilly. The fimple truss, reaching from pier to pier for the middle point of the arch, gives the strong support where it is most of all wanted; and in the lateral points H, although one leg of the truss is very oblique, the other

compensates for it by its upright position.

The chief peculiarity of this centre is to be feen in its base. This demands a more particular attention: but we must first make some observations on the condition of an arch, as it rests on the centering after the keystones are all set, and on the gradual transference of the pressure from the boards of the centering to the

joints of the arcliftones.

While all the archstones lie on the centering, the Observalower courses are also leaning pretty strongly on each tions on the other. But the mortar is hardly compressed in the state of an joints; and least of all in the joints near the crown. rests on the Suppose the arch to be Catenarean, or of any other centering. shape that is perfectly equilibrated: When the centering is gradually withdrawn, all the architones follow it. Their wedge-like form makes this impossible, without the middle ones squeezing the lateral ones aside. This compresses the mortar between them. As the stones thus come nearer to each other, those near the crown must defeend more than those near the haunches, before every stone has lessened its distance from the next by the fame quantity; for example, by the hundredth part of an inch. This circumstance alone must cause a finking in the crown, and a change of shape. But the joints near the crown are already more open than those near the liaunches. This produces a still greater change of form before all is fettled. Some maions enceavour to remedy, or at least to diminish, this, by using no

Excellence bridge.

. All thefe

good in

their kind.

mortar

flones dry, and even force them together by wedges and blocks laid between the stones on opposite sides of the crown: They afterwards pour in fine cement. This appears a good practice. Perronet rejects it, because the wedging fometimes breaks the stones. We should not think this any great harm; because the fracture will make them close where they would otherwise lie hollow. But, after all our care, there is still a finking of the crown of the arch. By gradually withdrawing the centering, the joints close, the architones begin to butt on each other, and to force afide the lateral courfes. This abutment gradually increasing, the pressure on the haunches of the centering is gradually diminished by the mutual abutment, and ceases entirely in that course, which is the lowest that formerly pressed it: it then ceases in the course above, and then in the third, and so on. And, in this manner, not only the centering quits the arch, gradually, from the bottom to the top, by its own retiring from it, but the arch also quits the centering by changing its shape. If the centering were now pushed up again, it would touch the arch first at the crown; and it must lift up that part gradually before it come again in contact with the haunches. It is evident, therefore, that an arch, built on a centre of a shape perfectly suited to equilibration, will not be in equilibrio when the centering is removed. It is therefore necessary to form the centering in fuch a manner (by raifing the crown), that it shall leave the arch of a proper form. This is a very delicate task, requiring a previous knowledge of the ensuing change of form. This cannot be ascertained by the help of any theory we are acquainted with.

But, suppose this attained, there is another difficulty: While the work advances, the centering is warped by the load laid on it, and continually increasing on each fide. The first pressure on the centering forces down the haunches, and raises the crown. The arch is therefore less curved at the haunches than is intended: the joints, however, accommodate themselves to this form, and are close, and filled with mortar. When the mafons approach the middle of the arch, the frame finks there, and rifes up at the haunches. This opens all the joints in that place on the upper side. By the time that the keystones are set, this warping has gone farther; and joints are opened on the under fide near the crown. It is true we are here speaking rather of an extreme case, when the centering is very flexible; but this occurred to Mr Perronet in the two great bridges of Neuilly and of Mantz. In this last one, the crown funk above a foot before the key was fet, and the joints at the haunches opened above an inchabove, while some nearer the crown opened near a quarter of an inch below.

In this condition of things, it is a delicate business to nues to strike the centering. Were it removed in an instant, 21 would probably come down; for the architones are not yet abutting on each other, and the joints in the middle are open below. Mr Perronet's method appears to us to be very judicious. He began to detach the centering at the very bottom, on each fide equally, where the pressure on the centering is very slight. He cut away the blocks which were immediately under each archstone. He proceeded gradually upwards in this way with some speed, till all was detached that had been put out of shape by the bending of the centering. This be-

intering.

mortar in the joints near the crown. They lay the ing no longer supported, sunk inward, till it was stopped Center. by the abutment which it found on the architones near the crown, which were still resting on their blocks. During part of this process, the open joints opened still more, and looked alarming. This was owing to the removal of the load from the haunches of the centering. This allowed the crown to fink full more, by forcing out the arch stones at the haunches. He now paused fonce days; and during this time the two haunches, now hanging in the air, gradually preffed in toward the centering, their outer joints closing in the meanwhile. The haunches were now preffing pretty hard on the arch-flones nearer the crown. He then proceeded more flowly, destroying the blocks and bridgings of these upper architones. As foon as he destroyed the support of one, it immediately yielded to the pressure of the haunch; and if the joint between it and the one adjoining toward the crown happened to be open, whether on the under or the upper fide, it immediately closed on it. But in proceeding thus, he found every stone sink a little while it closed on its neighbour; and this was like to produce a ragged foffet, which is a deformity. He therefore did not allow them to fink fo much. In the places of the blocks and bridgings which he had cut away, he set small billets, standing on their ends, between the centering and the archstones. These allowed the pendulous arch to push toward the crown without sensibly descending; for the billets were pushed out of the perpendicular, and some of them tumbled down. Proceeding in this way, he advanced to the very next course to the keystone on each side, the joints cloting all the way as he advanced. The last job was very troublesome; we mean the detaching the three uppermost courses from the centering : for the whole elafticity of the centering was now trying to unbend, and preffing hard against them. He found that they were lifted up; for the joints beyond them, which had closed completely, now opened again below: but this job was sinished in one day, and the centre fprung up two or three inches, and the whole arch funk about fix inches. This was an auxious time; for he dreaded the great momentum of fuch a valt mass of matter. It was hard to say where it would stop. He had the pleasure to see that it stopped very foon, fettling flowly as the mortar was compressed, and after one or two days settling no more. I'his fettling was very confiderable both in the bridge at Neuilly and in that at Mantz. In the former, the finking during the work amounted to 13 inches. It funk fix inches more when the blocks and bridgings were taken out, and 11 when the little standards were destroyed, and 11 more next day; fo that the whole finking of the pendulous arch was 91 inches, besides what it had funk by the bending and compression of the center-

The crown of the centering was an arch of a circle described with a radius of 150 feet; but by the finking of the arch its shape was considerably changed, and about 60 feet of it formed an arch of a circle whole radius was 2.14 feet. Hence Mr Perronet infers, that a semicircle of 500 feet span may be erected. It would no doubt be stronger than this arch, because its greater horizontal thrust would keep the stones firmer together. The finking of the arches at Mantz was not quite for great, but every thing proceeded in the same way. It amounted in all to 201 inches, of which 12 inches were owing

Center. owing to the compression and bending of the center- the work, made all this supposed roominess useless: be. Center.

26 The foregoing ob-

In fig. 5. no 1. may be observed an indication of this procedure of the masonry. There may be noticed a horizontal line ac, and a diagonal ab. These are supposed to be drawn on the masonry as it would have flood had the frames not yielded during the building. The dotted line A b' c' shews the shape which it took by the finking of the centering. The dotted line on the other fide was actually drawn on the masonry when the keystone was set; and the wavy black line on the fame fide shews the form which the dotted line took by the striking of the centering The undulated part of this line cuts its former position a little below the middle, going without it below, and falling within it above. This shews very distinctly the movement of the whole masonry, distinguishing the parts that were forced out

and the parts which funk inward.

We presume that the practical reader will think this account of the internal movements of a stupendous arch very instructive and useful. As Mr Perronet observed it to be uniformly the same in several very large arches which he erected, we may conclude that it is the general process of nature. We by no means have the con fidence in the durability or folidity of his arches which he prudently professes to have. We have conversed with some very experienced masons, who have also erected very great arches, and in very difficult fituations, which have given universal satisfaction; and we have found them uniformly of opinion, that an arch which has lettled to luch a proportion of its curvature as to change the radius from 150 to 244 feet, is in a very hazardous fituation. They think the hazard the greater, because the span of the arch is so great in proportion to its weight (as they express it very emphatically) or its height. The weight, fay they, of the haunches is too fmall for forcing together the keystones, which have fearcely any wedgelike form to keep them from sliding down. This is very good reasoning, and expresses very familiar notions. The mechanician would say, that the horizontal thrust at the crown is too small. When we questioned them about the propriety of Mr Perronet's method of removing the centering, they unanimously approved of its general principle, but faid that it was very ticklish indeed in the execution. The cases which he narrates were new to them. They should have almost despaired of success with arches which had gone so much out of shape by the bending of the centres; because, said they, the slope of the centering, to a great distance from the crown, was so little, that the archstones could not slide outwards along it, to close even the under fide of the joints which had opened above the haunches; fo that all the architones were at too great a distance from each other; and a great and general subfiding of the whole was necessary for bringing them even to touch each other. They had never observed fuch bendings of the centerings which they had em. ployed, having never allowed themselves to contract the feet of their truffes into fuch narrow spaces. They obferved, that nothing but lighters with their masts down can pals under the truffes, and that the fides must be so protected by advanced works from the accidental shock of a loaded boat, that there cannot be left room for more than one. They added, that the bridges of communication, necessary for the expeditious conducting of

fides, the business can hardly be so urgent and crowded anywhere, as to make the passage through every arch indispensably necessary. Nor was the inconvenience of this obstruction greatly complained of during the erec. tion of Westminster or Blackfriars bridges. Nothing should come in competition with the undoubted solidity of the centering and the future arch; and all boafting display of talent and ingenuity by an engineer, in the exhibition of the wonders of his art, is misplaced here.

These appeared to us good reasons for preferring the more cautious, and incomparably more fecure, construction of Mr Mylne, in which the breadth given to each base' of the trusses permitted a much more effective disposition of the abutting timbers, and also enabled the engineer to make it incomparably stiffer; fo that no change need be apprehended in the joints which have already closed, and in which the mortar has already taken its fet, and commenced an union that never can be restored if it be once broken in the smallest degree, no

not even by greater compression.

Here we beg leave to mention our notions of the The conconnection that is formed by mortar composed of lime nection or gypium. We confider it as confifting chiefly, if not that is folely, in a crystallization of the lime or gypfum and by mora water. As much water is taken up as is necessary for time, the formation of the crystals during their gradual con. &c. version into mild calcareous earth or alabatter, and the rest evaporates. When the free access of air is ablolutely prevented, the crystallization never proceeds to that state, even although the mortar becomes extremely dry and hard. We had an opportunity of observing this accidentally, when passing through Maestricht in 1770, while they were cutting up a massy revetment of a part of the fortifications more than 300 years old. The mortar between the bricks was harder than the bricks (which were Dutch clinkers, fuch as are now used only for the greatest loads); but when mixed with water it made it limewater, feemingly as strong as if fresh lime had been used. We observed the same thing in one small part of a huge mass of ancient Roman work near Romney in Kent; but the rest, and all the very old mortar that we have feen, was in a mild flate, and was generally much harder than what produced any lime water. Now when the mortar in the joints has begun its first crystallization, and is allowed to remain in perfect rest, we are confident that the subsequent crystals, whether of lime, or of calcarcous earth, or of gypfum, will be much larger and stronger than can ever be produced if they are once broken; and the farther that this crystallization has been carried, that is, the harder that the mortar has become, less of it remains to take any new crystallization. Why should it be otherwise here than in every other crystallization that we are acquainted with?

We think therefore that it is of great consequence Necessity to keep the joints in their first state if possible; and keeping the that the strength (as far as it depends on the mortar) joints in is greatly diminished by their opening; especially when their the mortar has acquired considerable hardness, which it state. will do in a month or fix weeks, if it be good. The cohesion given by mortar is indeed a mere trisle, when opposed to a force which tends to open the joints, acting, as it generally does, with the transverse force of a lever: but in fituations where the overload on any par-

(ter. ticular architones tends to push them down through between their neighbours, like wedges, the cohesion of the

mortar is then of very great consequence.

We must make another observation. Mr Perronet's ingenious process tended very effectually to close the joints. In doing this, the forces which he brought into action had little to oppose them; but as soon as they were closed, the contact of the parts formerly open opposed an obstruction incomparably greater, and immediately balanced a force which was but just able to turn the stone gently about the two edges in which it touched the adjoining stones. This is an important remark, though feemingly very triffing; and we wish the practitioner to have a very clear conception of it; but it would take a multitude of words to explain it. It is worth an experiment. Form a little arch of wooden blocks; and form one of these so, that when they are all resting on the centering, it may be open at the outer joint-Remove the centering - Then press on the arch at some distance from the open joint .- You will find that a very small pressure will make the arch bend till that joint closes-Press a little harder, and the arch will bend more, and the next joint will open .- Thus you will find that, by preffing alternately on each fide of the open joint, that stone can easily be made to stap over to either side; and that immediately after this is done the refistance increases greatly. This shews clearly, that a very moderate force, judiciously employed, will close the joints, but will not press the parts strongly together. The joints therefore are closed, but no more than closed, and are hanging only by the edges by which they were hanging while the joints were open. The arch, therefore, though apparently close and firm, is but loose and tottering. Mr Perronet tays, that his arches were firm, because hardly a stone was observed to chip or fplinter off at the edges by the fettlement. But he had done every thing to prevent this, by digging out the mortar from between the headers, to the depth of two inches, with faws made on purpose. But we are well informed, that before the year 1791 (twenty years after the erection) the arches at Neuilly had funk very fenfibly, and that very large splinters had flown off in feveral places. It could not be otherwise. The origi-Perro- nal conftruction was too bold; we may fay needlessly and oftentatiously bold. A very gentle slope of the roadway, which would not have flackened the mad gallop of a ducal carriage, nor fenfibly checked the laborious pull of a loaded waggon, and a proper difference in the fize of the arches, would have made this wonderful bridge incomparably stronger, and also much more elegant and pleafing to the eye. Indeed, it is far from being as handsome as it might have been. The ellipse is a most pleasing figure to every beholder; but this is concealed as much as possible, and it is attempted to give the whole the appearance of a tremendous lintel. It has the oppressive look of danger. It will SUPPL. VOL. I. Part I.

not be of long duration. The bridge at Mantz is still Centermore exceptionable, because its piers are tall and slender. If any one of the arches fails, the rest must fall in a moment. An arch of Blackfriars Bridge might be blown up without disturbing its neighbours.

Mr Perronet mentions another mode of firiking the A bad mecentering, which he fays is very usual in France. Every thod of second bridging is cut out. Some time after, every secutive. cond of the remainder; after this, every fecond of the remainder; and so on, till all are removed. This is never practifed in this country, and is certainly a very bad method. It leaves the arch hanging by a number of diflant points; and it is wonderful that any arch can bear

this treatment.

Our architects have generally proceeded with extreme caution. Wherever they could, they supported the centering by intermediate pillars, even when it was a truffed centre, having a tie-beam reaching from fide to fide. The centre was made to rest, not immediately on these The conta pillars, but on pieces of timber formed like acute wedges, mon meplaced in pairs, one above the other, and having the thed in point of the one on the thick end of the other. These Britain. wedges were well foaped and rubbed with black lead, to make them flippery. When the centres are to be flruck, men are stationed at each pair of the wedges with heavy mauls. They are directed to strike together on the opposite wedges. By this operation, the whole centering descends together; or, when any part of the arch is obferved to have opened its joints on the upper fide, the wedges below that part are flackened. The framing may perhaps bend a little, and allow that part to subfide. If any part of the arch is observed to open its joints on the under fide, the wedges below that part are allowed to stand after the rest have been slackened. By this process, the whole comes down gradually, and as flowly as we pleafe, and the defects of every part of the arch may be attended to. Indeed the caution and moderation of our builders have commonly been fuch, that few defects have been allowed to shew themselves. We are but little acquainted with joints opening to the extent of two inclies, and in fuch a cate would probably lift every flonc of the arch again (B). We have not employed truffed centerings fo much perhaps as we should have done; nor do we see their advantage (speaking as mere builders) over centres supported all over, and unchangeable in their form. Such centres must bend a little, and require loading on the middle to keep them in shape. Their compression and their elasticity are very troublesome in the striking of the centres in Mr Perronet's manner. The elasticity is indeed of use when the centres are struck in the way now described.

These observations on the management of the internal movements of a great arch, will enable the reader to appreciate all the merit of Mr Mylne's very ingenious construction. We proceed therefore to complete our

description.

Сс

(B) The writer of this article can only fay, that, after much inquiry, he has no information of any arch being received from the builder as sufficient that had suffered half the change of shape mentioned by Mr Perronet. The arch of Dublin bridge, built by an excellent, but a very private, mason, Mr Steven, is 105 feet wide, with only 22 feet of rife. It was erected (but not on a truffed centering) without changing one full inch in its elevation; and when the centering was removed, it funk only 13th inches, and about half an inch more when the parapets were added and the bridge completely finished.

uctions bold.

method

Blackfriars bridge enabled the architect to place a feries of five posts c, c, c, c, one on each stap of the pier; the ingenious contexture of which made it like one fo-The excel lid block of stone (fee ARCH, Supplement), These struts lence of Mr were gradually more and more oblique, till the outer one formed an obtuse angle with the lowest side of the interior polygon of the truss. On the top of these posts was laid a floping SEAT or beam D of flout oak, the upper part of which was formed like a zig-zag scarfing. The posts were not perpendicular to the under side of the feat. The angles next the pier were somewhat obtuse. Short pieces of wood were placed between the heads of the posts (but not mortised into them), to prevent them from slipping back. Each face of the scarf was covered with a thick and smooth plate of copper. The feet of the truss were mortised into a similar piece F, which may be called the SOLE of the truss, having its lower fide notched in the fame manner with the upper fide of D, and like it covered with copper. Between these two lay the STRIKING WEDGE E, the faces of which corresponded exactly with the slant faces of the seat and the sole. The wedge-was so placed, that the corresponding faces touched each other for about half of their length. A block of wood was put in at the broad end or base of this wedge, to keep it from slipping back during the laying the architones. Its outer end E was bound with iron, and had an iron bolt feveral inches long driven into it. The head of this bolt was broad enough to cover the whole wood of the wedge within the iron ferrule.

We presume that the reader, by this time, foresees the use of this wedge. It is to be driven in between the sole and the feat (having first taken out the block at the base of the wedge). As it advances into the wider spaces, the whole truss must descend, and be freed from the arch; but it will require prodigious blows to drive it back. Mr Mylne did not think fo, founding his expectation on what he faw in the launching of great thips, which flide very eafily on a flope of 10 or 12 degrees. He rather feared, that taking out the block behind would allow the wedge to be pushed back at once, so that the descent of the truss would be too rapid. However, to be certain of the operation, he had prepared an abundant force in a very ingenious manner. A heavy beam of oak, armed at the end with iron, was fuspended from two points of the centre like a battering ram, to be used in the same manner. Nothing could be more fimple in its structure, more powerful in its operation, or more easy in its management. Accordingly the success was to his wish. The wedge did not flip back of itself; and very moderate blows of the ram drove it back with the greatest ease. The whole operation was over in a very few minutes. The spectators had suspected, that the space allowed for the recess of the wedge was not sufficient for the settlement of the arch; but the architect trusted to the precautions he had taken in its construction. The reader, by turning to the article ARCH in this Supplement, will fee, that there was only the arch LY which could be expected to fettle: accordingly, the recess of the wedge was found to be much more than was necessary. However, had this not been the case, it was only necessary to take out the pieces between the polls below the feat, and then to drive back the heads of the struts; but this was

The gradual enlargement of the base of the piers of not needed (we believe) in any of the arches. We are Center well affired that none of the arches funk an inch and a half. The great arch of 100 feet foan did not fink one inch at the crown It could hardly be perceived whether the arch quitted the centering gradually or not, fo

small had been the changes of shape.

We have no hefitation in faying, that (if we except The great fome waste of great timber by uncommon joggling) the superiority whole of this performance is the most perfect of any of the cen that has come to our knowledge. We doubt not but tering uld that several have equalled it, or may have excelled it; by him. but we do not know of them: and we think, that the bringing forward fuch performances is no lefs ferviceable to the public than it is honourable to the inventor. Nor do we suppose that any views of interest can be so powerful as to prevent an ingenious architect from communicating to the public fuch honourable specimens of his own talents. We should be happy to communicate more of this kind; for we consider it as a very important article of practical mechanics, and think that it is. of confequence to the nation that it should be very generally understood. In every corner of the country bridges are to be built - we have everywhere good mafons, who are fully able to execute any practicable project, but too little acquainted with principle to invent, or to accommodate even what they know to local circumflances, and are very apt to be duped by appearances of ingenuity, or misled by erroneous notions of the strains which are excited. We profess more science, and to treat the subject with the assistance of accurate principles: But while we are certain that every circumstance is susceptible of the most accurate determination, we must acknowledge that we have by no means attained an accurate knowledge of all the strains which are produced and excited in a frame of carpentry, which is fettling and changing its shape, even though it be not very complicated; far less are we possessed of a clear view of what happens in a mass of masonry in similar conditions. Therefore, though we speak with the strong belief of our being right, we fpeak with a fense of our fallibility, and with great deference to the judgment of eminent and experienced architects and engineers. We should consider their free and candid criticisms as the highest favour; and we even solicit them, with assurances of thanks, and that we will take fome opportunity, before the close of this work, to acknowledge and correct our mistakes We even presume to hope, that the liberal minded artist will be pleased with this opportunity which we give him of increasing the national flock of knowledge. Let mutual jealoufy and rivalship reign in the breafts, and prompt the exertions, of our restless neighbours on the continent-let them think that the dignity of man confifts in perpetual warfare, in which every individual feels himself indebted only to himself, freed from all the sweet ties of domestic partiality, of friendship, and of patriotic attachment. We hope that the hearts of Britons will long continue to be warmed and fortified by the thoughts of mutual affiftance, mutual co-operation, mutual attachment, and a patriotic preference of their countrymen to all other men. While these sentiments are regulated by unshaken honesty, by candour, and by Christian charity, we thall be fecured from the errors of partial attachments, and yet enjoy all the pleasures of unsophistcated nature. Families will still be bound together by the affectionate

will be in harmony with the bonds which connect the members of each family, by their endless croffings and intermixings. In this state, the state of focial nature, the man of talents will not lock up all the fruits of his exertions in his own breaft, but will feel a pleafure in imparting them to a fociety that is dear to him, and on which he depends for all his best enjoyments. Nothing will hold the good man back when this is in his power, but the virtuous use which he can make of his superiority in the discharge of his own little circle of duties. This is all that is required of true patriotiim; and it is not too much to be expected from Britons, who feel a pleasure in viewing their country as the great school of the arts, under the patronage of a fovereign who has done more for their improvement than all the other princes of Europe, and who (we are well affured) is now meditating a plan which must be highly gratifying to every eminent professor of the arts.

THE subject which we have been considering is very je of this closely connected with the construction of wooden ar e con-bridges. These are not always constructed on the sole principles of equilibrium, by means of mutual abutment. Attion of They are stiff frames of carpentry, where, by a proper disposition, beams are put into a state of extension, as well as of compression, so as to stand in place of solid bi ges. bodies as big as the spaces which the beams inclose; and thus we are enabled to couple two, three, or four of these together, and set them in abutment with each other like mighty architones. We shall close this artiele, therefore, with two or three specimens of wooden bridges, disposed in a series of progressive composition, fo as to serve as a fort of introduction to the art in general, and furnish a principle which will enable the intelligent and cautious artift to push it with confidence as far as it can go.

The general problem is this. Suppose that a bridge te XVI, is to be thrown over the space AB (fig. 9.), and that this is too wide for the strength of the fize of timber which is at our command; how may this beam AB be supported with sufficient effect? There are but two ways in which the middle point C (where the greatest strain is) can be supported: 1. It may be suspended by two ropes, iron rods, or wooden ties, DC, EC, made fast to two firm points D, E, above it; or it may rest on the ridge of two rafters dC, eC, which rest on two firm points d, e below it. 2. It may be supported by connecting it with a point so supported; and this connection may be formed, either by suspending it from this point, or by a post reiting on it. Thus it may hang, by means of a rod or a king-post FC, from the ridge F of two rafters AF, BF; or it may rest on the strut Cf, whose lower extremity f is carried by the ropes, rods, or wooden ties Af, Bf,

Whichfoever of these methods we employ, it follows, from the principles of carpentry, that the support given to the point C is so much the more powerful, as we make the angle DCE, or dCe, or the equivalent angles AFB, or AfB, more acute.

Each of these methods may be supposed equally strong. Our choice will depend chiefly on the facility of finding the proper points of support D, E, d, e; except in the second ease, where we require no fixed points but A and B. The simple torms of the first case require a great

The ties of blood; and the whole frame of British society extent of figure. Very rarely can we suspend it from Center. have depth enough of bank to allow the support of the Phe usual rafters dC, eC; but we can always find room for the and fimples fimple trufs AFB. This therefore is the most usually me had of

In the construction, we must follow the maxims and bridges. directions prescribed in the article CARPENTRY of this volume, and the article Roor of the Encycl. The beams FA, FB must be mortised into AB, in the firmest manner, and there secured with straps and bolts; and the middle must hang by a strap attached to the king polt FC, or to the iron rod that is used for a king post. No mortifing in the point C must be employed; it is unnecessary, and it is hurtful, because it weakens the beam, and because it lodges water, and soon decays by rot. The best practice is not to suspend the beam immediately by this strap, but to let it rest, as in fig. 10. on a beam C, which croffes the bridge below, and has its other end supported in the same manner by the other

It is evident that the length of the king post has no effect on the support of C. We may therefore contract every thing, and preserve the same strength of support, by finding two points a and b (fig. 11.) in the banks, at a moderate distance below A and B, and setting up the rafters a F, b F, and suspending C from the shortened king post. In this construction, when the beam AB rests on a cross bearer, as is drawn here, the struts a F, b F are kept clear of it. No connection between them is necessary, and it may be hurtful, by inducing cross strains on both. It will, however, greatly increase the sliffues of the whole. This construction may safely be loaded with ten times the weight that AB can carry

Suppose this done, and that the feantling of AB is $_{A ext{n im}}$. too weak for carrying the weight which may be brought provement on the parts AC, CB. We may now trufs up each of that mehalf, as in fig. 12. and then the whole will form a hand. thod. fome bridge, of the simplest construction possible. The interfections of the fecondary braces with those of the main truss will form a hand-rail of agreeable figure.

We are not confined to the employment of an entire piece AB, nor to a rectilineal form. We may frame the bridge as in fig. 13. and in this form we diffuade from allowing any connection with the middle points of the main braces. This construction also may be followed till each beam AC and CB is loaded to ten times what it can fafely bear without the fecondary

truffing. There is another way by which a bridge of one beam Another may be supported beyond the power of the first and method. simplest construction. This is represented in fig. 14. and fig. 15. The trufs beam FG thould occupy onethird of AB. The advantage of this confluction is very confiderable. The great elevation of the braces (which is a principal element of the firength) is preferved, and the braces are greatly shortened.

This method may be pushed still farther, as in fig.

And all these methods may be combined, by joining These methe constructions of fig. 14 and fig. 15. with that of thods com-

In all of them there is much room for the display of skill, in the proper adjustment of the scantling of the Cc2

Center. timber, and the obliquity of the braces to the lengths of the different bearings. A very oblique strut, or a flender one, will fuffice for a small load, and may often give an opportunity to increase the general strength; while the great timbers and upright supports are referved for the main pressures. Nothing will improve the composition so much as reflecting progressively, and in the order of these examples, on the whole. This alone can preserve the great principle in its simplicity and full

The ele These constructions are the elements of all that can ments of all be done in the art of building wooden bridges, and are that can be to be found more or less obviously and distinctly in all done in this attempts of this kind. We may affert, that the more

obviously they appear, the more perfect the bridge will be. It is aftonishing to what extent the principle may be carried. We have seen a bridge of 42 feet span formed of two oak truffes, the biggest timber of which did not exceed fix inches square, bearing with perfect steadiness and safety a waggon loaded with more than two tons, drawn by four front horses. It was framed as fig. 16 nearly, with the addition of the dotted lines, and was near thirty years old; protected, however, from the weather by a wooden roof, as many bridges in Germany are.

We recollect another in the neighbourhood of Stettin, which seemed constructed with great judgment and spirit. It had a carriage road in the middle about 20 feet (we think) wide, and on each fide a foot way about five feet wide. The span was not less than 60 feet, and the greatest scantling did not appear to exceed 10

inches by 6.

This bridge confifted of four truffes, two of which formed the outfide of the bridge, and the other two made the separation between the carriage road and the two foot ways. We noticed the construction of the truffes very particularly, and found it fimilar to the laft, except in the middle division of the upper truss, which,

being very long, was double truffed, as in fig. 17.

The reader will find in that volume of Leupold's Theatrum Machinarum, which he calls Theatrum Pontificum, many specimens of wooden bridges, which are very frequent in the champain parts of Germany. They are not, in general, models of mechanic art; but the reflecting reader, who confiders them carefully, will pick up here and there subordinate hints, which are ingenious, and may fometimes be useful.

What we have now exhibited are not to be confidered

as models of construction, but as elementary examples and lessons, for leading the reader systematically into a

thorough conception of the subject.

We cannot quit the subject without taking notice of a very wonderful bridge at Wittingen in Switzerland, in Switzer- flightly described by Mr Coxe (Travels, vol. I. 132.) It is of a construction more simple still than the bridges we have been describing. The span is 230 feet, and it rifes only 25. The sketch (fig. 18.) will make it sufficiently intelligible. ABC is one of two great arches, approaching to a Catenarean shape, built up of seven courses of solid logs of oak, in lengths of 12 or 14 feet, and 16 inches or more in thickness. These are all picked of a natural shape, suited to the intended curve; so that the wood is nowhere cut across the grain to trim it into shape. These logs are laid above each other, so that their abutting joints are alternate, like

those of a brick wall; and it is indeed a wooden wall, Center fimply built up, by laying the pieces upon each other, taking care to make the abutting joints as close as posfible. They are not fastened together by pins or bolts, or by fearfings of any kind. They are, however, held together by iron straps, which surround them, at the diffance of five feet from each other, where they are fastened by bolts and keys.

E

These two arches having been erected (by the help, we prefume, of pillars, or a centering of some kind), and well butted against the rock on each fide, were freed from their supports, and allowed to fettle. They are so placed, that the intended road abc intersects them about the middle of their height. The roadway is supported by cross joists, which rest on a long horizontal fummer beam. This is connected with the arches on each fide by uprights bolted into them. The whole is covered with a roof, which projects over the arches on each fide to defend them from the weather. Three of the spaces between these uprights have struts or braces, which give the upper work a fort of truffing in that

This construction is simple and artless; and appears, by the attempt to truls the ends, to be the performance of a person ignorant of principle, who has taken the whole notion from a stone arch. It is, however, of a firength much more than adequate to any load that canbe laid on it. Mr Coxe fays, but does not explain how, that it is so contrived that any part of it can be repaired independent of the rest. It was the last work of one Ulrich Grubenhamm of Tuffen, in the canton of Appenzel, a carpenter without education, but celebrated for teveral works of the fame kind; particularly the bridge over the Rhine at Schafhausen, confisting of two arches, one of 172 and the other of 193 feet ipan, both resting on a small rock near the middle of the river.

While writing this article, we got an account of a wooden bridge erected in North America, in which this fimple notion of Grubenhamm's is mightily improved. The span of the arch was faid to exceed 250 feet, and its rife exceedingly small. The description we got is very general, but sufficient, we think, to make it per-

fectly intelligible.

In fig. 19. DD, EE, FF, are supposed to be three Another in beams of the arch. They confift of logs of timber of North small lengths, suppose of 10 or 12 feet such as can be America. found of a curvature fuited to its place in the arch without trimming it across the grain. Each beam is double, confilling of two logs applied to each other, fide to fide, and breaking joint, as the workmen term it They are kept together by wedges and keys driven through them

at short intervals, as at K, L, &c.

The manner of joining and strongly binding the two fide pieces of each beam is shewn in fig. 20. The mortife aicb and dcio, which is cut in each half beam, is confiderably longer on the outfide than on the infide, where the two mortiles meet. Two keys, BB and CC, are formed, each with a notch bed, or aio, on its fide; which notch fits one end of the mortife. The inner fide of the key is straight, but so formed, that when both keys are in their places, they leave a space between them wider at one end than at the other. A wedge AA, having the fame taper as the space just mentioned, is put into it and driven hard. It is evident that this must hold the two logs firmly together.

This is a way of uniting timber not mentioned in the article CARPENTRY; and it has fome peculiarities worthy of notice. In the first place, it may be employed fo as to produce a very strong lateral connection, and would then co operate finely with the other artificial methods of scarfing and tabling that we described in the article referred to. But it requires nice attention to some circumstances of construction to secure this effect. If the joints are accurately formed to each other, as if the whole had been one piece divided by an infinitely thin faw, this manner of joining will keep them all in their places. But no driving of the wedge AA will make them firmer, or cause one piece to press hard on the other. If the abutment of two parts of the hali beam is already close, it will remain so; but if open in the smallest degree, driving of the wedge will not make it tighter. In this respect, therefore, it is not fo proper as the forms described in CARPENTRY.

In order that the method now deteribed may have the effect of drawing the halves of the beams together, and of keeping them hard squeezed on each other, the joints must be made so as not to correspond exactly. The prominent angle aio (fig. 21.), formed by the ends of the two half mortifes, must be made a little more obtufe than the angle a fo of the notch of the key which this prominence is intended to fill up. Moreover, the opposite side et of this key should not be quite straight, but a very little convex. With these precautions, it is easy to fee that, by driving the wedge AA, we cause the notch a fo to take hold, first at the two points a and o, and then, by continuing to drive the wedge, the fides af, of, of the notch gradually compress the wood of the half beams, and press them on each other. By continuing to drive the wedge, the mutual compression of the key and the beam squeezes all together, and the space a foi is completely filled up. We may see, from this process, that the mutual compression and drawing together of the timber will be greater in proportion as we make the angle a io more prominent, and its correfoonding anyle a fo more deep; always taking care that the key shall be thick enough not to break in the narrow part.

This adjustment of the keys to the mortise is necesfary on another account. Supposing the joints to fit each other exactly before driving the wedge, and that the whole shrinks a little by drying—by this the angle aio will become more prominent, and the angle afo will become more shallow; the joint will open at a and o, and the mutual compressure will be at an end.

We may also observe, that this method will not give any additional firmness to the abutments of the different lengths employed to piece out the arch beam; in which respect it differs materially from the other modes of join-

ing timber. Having shown how each beam is pieced together, we must now show how a number of them are united, so as to compose an arch of any thickness. This is done in the very same way. The beams have other mortises worked out of their inner fides, half out of each half of the beam. The ends of the mortifes are formed in the same way with those already described. Long keys BB, CC, (fig. 19.) are made to fit them properly, the notches being placed fo as to keep the beams at a proper distance from each other. It is now plain that driving in a long wedge AA will bind all together.

In this manner may an arch be extended to any fpan, Center. and made of any thickness of arching. The bridge over Portsmouth river, in North America, was more than 250 feet in length, and confided of feveral parallel arches of beams. The inventor (we think that his name is Bludget) faid that he found the strength fo great, that he could with perfect confidence make one of four times the span.

We admire the ingenuity of this construction, and think it very effectual for bringing the timbers into firm and uniform abutment; but we imagine that it requiresequilibration, because it is extremely flexible. There is nothing to keep it from bending, by an inequality of load, but the transverie strength of the beams. The keys and wedges can have very little power to prevent this bending. The distance between the beams will also contribute little or nothing to the stiffness; nay, we imagine that a great distance between them will make the frame more flexible. Could the beams be placed fo near each other that they could be fomehow joggled on each other, the whole would be fliffer; but at present they will bend like the plates of a coachspring. But nothing hinders us from adding diagonal pieces to this construction, which will give it any degree of stiffness, and will enable it to bear any inequality of loading. When completed in this manner, we imagine that it will be at least equal to any construction that has yet been thought of. One advantage it possesses that is very precious: Any piece that tails may be taken out, and replaced by another, without disturbing the rest, and without the smallest risk. On the whole, we think it a very valuable addition to British carpentry. The method here practifed, both for joining the parts of one beam and for framing the different beams together, suggests the most firm and light constructions for dome-roofs that can be conceived: incomparably superior to any that have yet been erected. The whole may be framed, without a nail or a spike, into one net-like shell that cannot even be pulled in pieces. We may perhaps confider this in another article; at prefent we return to the confideration of truffed bridges.

When the width of the river exceeds what is thought Bridges practicable by a fingle trus, we must then combine, combined either by simple addition, or by composition, different by simple truffes together. We compose a bridge by simple ad-addition or dition when we make a frame of carpentry of an un-by composition. changeable and proper shape, to serve as one of the architones of a bridge of masonry. This may easily be comprehended by looking at fig. 22. Each of the frames A, B, C, D, must be considered as a separate body, and all are supported by their mutual abutment. The nature of the thing is not changed, although we suppose that the rails of the frame B, instead of being mortised into an upright b'b', unconnected with the frame C, is mortifed into the upright cc of that frame, the direction and intensity of the mutual pressures of the two frames are the fame in both cases; accordingly this is a very common form of small wooden bridges. It is usual, indeed, to put diagonal battens into each: but we believe that this is more frequently done to please the eye than to produce an unalterable shape of each frame.

To an unskilful carpenter this bridge does not feem effentially different from the centering of Mr Hupeau for the bridge of Orleans; and indeed, in many cases,

tinguish rent mea thods.

Center. it requires reflection, and sometimes very minute reflection, to diffinguish between a construction which is only an addition of frame to frame till the width be covered, from a construction where one frame works on the adjoining one transversely, pushing it in one part, and

How to dif- ad a real transversely.

The ready way for an unlettered artill to form a just notion of this point, is to examine whether he may faw through the connecting piece formed ac- b' b' from one end to the other, and make them two cording to separate frames. Whenever this cannot be done without that part opening, it is a confiruction by composition. Some of the beams are on the Bretch; and iron straps, extending along both pieces, are necessary for securing the joint. The bridge is no longer a piece of masonry, but a performance of pure carpentry, depending on principles peculiar to that art. Equilibration is necessary in the first construction; but, in the second, any inequality of loading is made ineffectual for hurting the edifice, by means of the stretch that is made to operate on some other piece. We are of opinion, that this most simple employment of the distinguishing principle of carpentry, by which the beams are made to act as ties, will give the most perfect construction of a wide bridge. One polygon alone should contain the whole of the abutments; and one other polygon should consist entirely of ties; and the beams which form the radii, connecting the angles of the two polygons, complete the whole. By confining the attention to these two simple objects, the abutments of the outer polygon, and the joints of the inner one, may be formed in the most simple and efficient manner, without any collateral connections and dependencies, which divide the attention, increase the complication, and commonly produce unexpected and hurtful strains. It was for this reason that we have so frequently recommended the centering of the bridge of Orleans. Its office will be completely performed by a truss of the form of fig. 23.; where the polygon ABCDEF, confilling of two layers of beams (if one is not fufficient), contains the whole abutments, and the other AbcdeF is nothing but an iron rod. In this construction, the obtuseness of the angles of the lower polygon is rather an advantage. The braces Gc, Gd, which are wanted for trufsing the middle of the outer beams, will effectually fecure the angles of the exterior polygon against all risk of change. The reader must perceive that we have now terminated in the construction of the Norman roof. We indeed think it the best general form, when some moderate declivity is not an infuparable objection. When this is the case, we recommend the general plan of the centering of the bridge of Orleans. We would make the bridge (we speak of a great bridge) consist of four truffes; two to ferve as the outfides of the bridge, and two inner truffes, feparating the carriage-way from the foot-paths. The road should follow the course of the lower polygon, and the main trufs should form the rails. It might look strange; but we are here speaking of flrength; and evident, but not unwieldy, flrength, once it becomes tamiliar, is the furest squrce of beauty in all works of this kind.

CENTRE of Friction, is that point in the base of a body on which it revolves; into which, if the whole furface of he base, and the mais of the body, were collected, and made to revolve about the centre of the base of the given body, the angular velocity destroyed

by its friction would be equal to the angular velocity destroyed in the given body by its friction in the same time. See FRICTION in this Supplement.

CENTRE of Gyration, is that point in which, if the whole mass be collected, the same angular velocity will be generated in the same time, by a given force acting at any place, as in the body or fyttem itself. This point differs from the centre of oscillation, in as much as in this latter case the motion of the body is produced by the gravity of its own particles; but, in the case of the centre of gyration, the body is put in motion by some other force acting at one place only.

GENTRE of Ofcillation, is that point in the axis or line of suspension of a vibrating body, or system of bodies, in which, if the whole matter or weight be collected, the vibrations will still be performed in the same time, and with the fame angular velocity, as before. Hence, in a compound pendulum, its diftance from the point of suspension is equal to the length of a simple pendulum whose oscillations are isochronal with those of the compound one.

- CENTRE of Prefure, of a fluid against a plane, is that point against which a force being applied equal and contrary to the whole pressure, it will just sustain it, so as that the body preffed on will not incline to either fide. - This is the fame as the centre of percuffion, fupposing the axis of motion to be at the intersection of this plane with the furface of the fluid; and the centre of pressure upon a plane parallel to the horizon, or upon any plane where the pressure is uniform, is the same as the centre of gravity of that plane.

CENTROBARICO, the fame as centre of gravity. CENTROBARIC METHOD, is a method of determining the quantity of a furface or folid, by means of the generating line or plane and its centre of gravity. The doctrine is chiefly comprised in this theorem:

Every figure, whether superficial or folid, generated by the motion of a line or plane, is equal to the product of the generating magnitude and the path of its centre of gravity, or the line which its centre of gravity describes.

CERUSE, or WHITE-LEAD, is a fubstance so much used in painting, and for other purposes, that numerous modes have been employed for the preparation of it. Of the most common of these, a sufficient account has been given in the Encyclopædia (fee CERUSE, and the fame word CHEMISTRY-Index); but Lord Dundonald has discovered a more expeditious and facile method than any of them, which becomes the more ufeful, as the substance with which it is effected has been hitherto rejected by the chemical world as a caput mor-

His lordship directs common lead to be reduced to a calx, but not too fine, and to have a proportion of fivefixth parts thereof, intimately mixed with muriate, or solution of potass. In this state, he directs it to be frequently flired, in order to have the new surfaces of the mixture exposed to the carbonic acid of atmospheric air; as his lordship ohserves, that the effects of the carbonic acid on the alkali existing in the present state of the mixture is esentially necessary, in order to effect the intended purpose. In this state, it is to be frequently fprinkled with water; and, after the calx has been long enough immerfed with the muriate to be fufficiently operated upon, the muriate is to be legigated by com-

The best general form of a wonden bridge.

evaporation, in order to be made use of at a future period with other calx. The calx is to be afterwards ground, levigated, and dried for use.

E

For this discovery, his lordship obtained a patent on the 18th of August 1797; and the success which has attended the former patents of this scientific nobleman leads us to conclude, that the present discovery is cn-

titled to the attention of the public.

CHAMBERS (Sir William), the celebrated architect, was descended of the ancient family of Chalmers in Scotland, barons of Tartas, in France. His grandfather inffered confiderably in his fortune by fupplying Charles XII. of Sweden with money, &c. which that monarch repaid in base coin. Sir William's father resided several years in Sweden to recover his claims; and there Sir Wilham was born, and, at eighteen years of age, appointed Supercargo to the Swedish East India company. From a voyage which he made to China, he brought home the Afratic style of ornament, in tents, temples, mosques, and pagodas. These ornaments (through the interest of lord Bute) he was enabled to apply in the gardens at Kew. Patronifed by the princefs dowager and the king, Mr Chambers had much of the fashionable business of the day. Under Burke's reform, he was appointed furveyor general of the board of works. Somerfet house was worth to him at least I. 2000 a year. His Chef d'œuvres are his staircases, particularly those at Lord Besborough's, Lord Gower's, and the Royal and Antiquarian Societies. The terrace behind Somerfet house is a bold effort of conception. His defigns for interior arrangements were excellent. His Treatife on Civil Architecture alone will immortalize his name. In private life, Sir William was hospitable, kind, and amiable. His fon married Miss Rodney; Mr Cotton, Mr Innis, and Mr Harward, married his beautiful daughters. Having been abstemious in his youth, Sir William's constitution did not begin to break till he was seventy years of age. For the last three years, he was kept alive by wine and oxygenated air; and died on the 5th of March 1796. His celebrity will be lafting in the works which he has left; and, as he was equally skilled in the theory and practice of the arts which he professed, his precepts are as valuable as his works. At his death, he was fellow of the Royal and Antiquarian Societies, treasurer of the Royal Academy, furveyor general of the board of works, and knight of the Swedish order of the Polar Star.

CHAMFER, or CHAMFERET, an ornament, in are chitecture, confitting of half a fcotia; being a kind of

fmall furrow or gutter on a column.

CHAPPE (Jean d'Auteroche), a French aftronomer, was born at Mauriac, in Auvergne, March 2. 1728. A taste for drawing and mathematics appeared in him at a very tender age; and he owed to Dom Germain a knowledge of the first elements of mathematics and astronomy. M. Cassini, after affuring himself of the genius of this young man, undertook to improve it. He employed him upon the map of France, and the translation of Halley's tables, to which he made considerable additions. The king charged him in 1753 with drawing the plan of the county of Bitche, in Lorraine, all the elements of which he determined geographically. He occupied himself greatly with the two comets of 1760; and the fruit of his labour was his

elementary treatife on the theory of those comets, enriched with observations on the zodiacal light, and on the aurora borealis. He soon after went to Tobolsk, in Siberia, to observe the transit of Venus over the sun; a journey which greatly impaired his health. After two years absence he returned to France in 1762, where he occupied himself for some time in putting in order the great quantity of observations he had made. M. Chappe also went to observe the next transit of Venus, viz. that of 1769, at California, on the west side of North America, where he died of a dangerous epidemic disease, the 1st of August 1769. He had been named adjunct astronomer to the academy the 17th of January 1759.

The published works of M. Chappe, are, 1. The Astronomical Tables of Dr Halley, with Observations and Additions, in 8vo, 1754. 2. Voyage to California, to Observe the Transit of Venus over the Sun, the 3d of June 1769; in 4to, 1772. 3. He had a considerable number of papers inserted in the Memoirs of the Academy, for the years 1760, 1761, 1764, 1765, 1766, 1767, and 1768; chiefly relating to astronomical

matters

UNIVERSAL CHARACTERS, could they be introduced, would contribute so much to the diffusion of useful knowledge, that every attempt to make such a fcheme simple and practicable is at least entitled to notice. Accordingly, in the Encyclopædia Britannica, under the word CHARACTER, a short account is given of the principal plans of univerfal characters which had then fallen under our observation; but since that article was published, a new method of writing, by which the various nations of the earth may communicate their fentiments to each other, has been proposed by Thomas Northmore, Efq; of Queen-street, Mayfair. It bears some resemblance to that which we have given from the Journal Literaire, 1720, but it is not the same; and of the two, Mr Northmore's is perhaps the most ingenious. 'The ground-work of the superstructure differs not indeed from that of the journalist, being this in both, "That if the same numerical figure be made to repres fent the fame word in the various languages upon earth, an universal character is immediately obtained." The only objection which our author or his friends faw to fuch a plan, originates in the diverfity of idioms; but; as he truly observes, every schoolboy has this difficulty to encounter as often as he construes Terence.

Such then was Mr Northmore's original plan: but he foon perceived that it was capable of confiderable improvement; for, instead of using a figure for every word; it will be necessary to apply one only to every useful word; and we all know how few words are absolutely necessary to the communication of our thoughts. Even these may be much abbreviated by the adoption of certain uniform fixed signs (not amounting to above 20), for the various cases, numbers, genders, degrees of comparison, of nouns, tenses, and moods, of verbs, &c. All words of negation, too, may be expressed by a prefixed sign. A few instances will best explain the author's

eaning.

Suppose the number 5 to represent the word fee,

6 — — a man,

7 — happy,

8 — — never,

Characters. "I would then (fays he) express the tenses, genders, cases, &c. in all languages, in some such uniform manner as following:

(1)	5	==	present tense, -	fee,
(2)	-5	Miles	perfect tense,	faw,
(3)	:5	Probability Standards	perfed participle, -	feen,
(4)	5:	Married Married	present participle, -	feeing,
(5)	5.	-	future, -	will fee,
(6)	5	==	fubstantive, -	fight,
(7)	5	markets beares	personal substantive, -	spectator,
(8)	6		nominative case, -	a man,
(9)	6	==	genitive, -	of a man,
(10)	6	Mirror Service	dative, -	to a man,
(11)	6	- majori	feminine, -	a woman,
(12)-	+6	=.	plural, — —	men,
(13)	7	desirent periode	positive,	happy,
(14)	7	-	comparative, -	happier,
(15)	7	==	Superlative, -	happiest,
	7	entropy, sellprov	as above, N° 6	happiness,
(16)-	-7	==	negation,	unhappy.

"From the above specimen, I should find no difficulty in comprehending the following sentence, though it were written in the language of the Hottentots:

9, 8, .5, -7, 6. I never faw a more unhappy woman.

"Those languages which do not use the pronoun prefixed to the verb, as the Greek and Roman, &c. may apply it, in a small character, simply to denominate the person; thus, instead of 9, 8, 5, I never saw; they may write, 8, 9.5, which will signify that the verb is in the first person, and will still have the same meaning."

Our author feems confident that, according to this scheme of an universal character, about 20 figns, and less than 10,000 chosen words (synonyms being set a fide), would answer all the ends proposed; and that foreigners, by referring to their numerical dictionary, would easily comprehend each other. He proceeds next to shew how appropriate sounds may be given to his signs, and an universal living language formed from the universal characters.

To attain this end, he proposes to distinguish the ten numerals by ten monosyllabic names of easy pronunciation, and such as may run without difficulty into one another. To illustrate his scheme, however, he calls them, for the present, by their common English names; but would pronounce each number made use of by uttering separately its component parts, after the manner of accountants. Thus let the number 6943 represent the word borse, he would not, in the universal language, call a horse six thousand nine hundred and forty-three, but six, nine, four, three, and so on for all the words of a sentence, making the proper stop at the end of each. In the same manner, a distinct appellation must be appropriated to each of the presixed signs, to be pronounced immediately after the numeral to which it is an ap-

pendage. Thus if plu be the appellation or the fign of Charache the plural number, fix, nine, four, three, plu will be Chaumen horfes.

Thus (fays our author), I hope, it is evident that about 30 or 40 diffinet fyllables are sufficient for the above purpose; but I am much mistaken if eleven only will not answer the same end. This is to be done by substituting the first 20 or 30 numerals for the signs, and saying, as in algebra, that a term is in the power of such a number, which may be expressed by the simple word under. Ex. gr. Let 6943 represent the word borse; and suppose 4 to be the sign of the plural number. I would write the word thus, \$\frac{4}{5\sigma_1}\$; and pronounce it, six, nine, sour, three, in the power of or under four. By these means eleven distinct appellations would be sufficient, and time and use would much abbreviate the pronunciation."

To refuse the praise of ingenuity to this contrivance for an universal language would be very unjust; but elocution in this manner would be so very tedious, that surely the author himself, when he thinks more coolly on the subject, will perceive, that in the living speech its defects would more than balance its advantages. A pangraph, as he calls his universal character, would indeed be useful, and is certainly practicable; a panleg (if we may form such a word) would not be very useful, unless it were much more perfect than it could be made according to the plan before us.

CHAUMETTE (Pierre Gasparine), though a man of talents and an author, would hardly have deserved a place in this work, did not his life and the manner of his death hold out an awful warning against those principles which produced the overthrow of social order in France.

He was a native of the town of Nevers, in the Orleanois; and as he rose to the office of recorder in Paris, few men excited more attention in France for a time, or had a more hateful talk to perform, during the most tragical part of the revolution, than Chaumette. He had been bred to the sea; but not relishing that life, and failing to obtain expected preferment therein, he quitted it, and lived by the use of his pen, which he certainly knew how to manage more to his profit than the compass. He could, however, speak better, and more fluently, than he could write. He had also been employed as a librarian and amanuenfis to a dignitary of the church, in the diocese of Nivernois; but at the commencement of the troubles in France, he was actually a clerk to an attorney, and occasionally wrote for the newspapers, as well as trifles for the stage. He was one of the chief disciples of Camille Desmoulins, and among the first who put the tri-coloured cockade in his hat just before the taking of the Bastille. He greatly out-ran that apostle in zeal for the new faith; for when Camille was composing the first number of his Vieux Cordelier, with the hope of tranquilifing the overheated imaginations of the leaders of that great event, and tempering the public rage against the real or supposed enemies of the new order of things, Chaumette was still farther inflaming it, and directing it in vengeance against particular individuals. It was Chaumette that instigated the commune of Paris to demand the trial of the queen, and he was of the committee which prepared the charges and regulated the evidence against that ill-fated woman. He was himself a witness too against

than the her at the revolutionary tribunal, and undertook to re- the veil which covered the workings of the plot, and an-Chaumette primand M. la Tour Dupin, lately war minister to Louis XVI. for not exposing those parts of Antoinette's conduct, which, it was infifted on, he was privy to or acquainted with.

The most infamous part of Chaumette's conduct on that occasion was his accusing the queen of an incestuous connection with her fon. Even the horrid tribunal was shocked at this infinuation, of which the author became instantly the object of almost universal abhorrence; and Robespierre himself, under whose auspices Chanmette was believed to act, grew outrageous when he was told of a charge fo fcandaloufly abfurd. "The fool (exclaimed he)! was it not enough that he had proved her a Messalina, but he must make her an Agrippina too!" Of proof indeed there was not much; and the feverest enemy of the beautiful Antoinette, if his mind be not wholly warped by prejudice, will admit, that by these brethren in iniquity she was murdered under the form of a revolutionary trial.

Robespierre had sense enough to see that this abominable conduct of Chaumette would hurt the cause in which they were both embarked; and for that reason he never forgave him, though he allowed the zeal to continue to operate on inferior objects, till it whelmed the zealot himself in ruin. Chaumette had credit now with none but the very foum of the revolution; and fuch recrementitious matter will always be thrown off in na-

tional ebullitions of this kind.

Robespierre was at this time in the very zenith of his power, yet Chaumette moved fuch a proposition in the full commune, as gave reason to many to believe that he would fet up as his rival in the city. This daring motion was for uniting all the heads of the 48 fections of Paris in one council; a measure that would have fuperseded the force of the legislature itself, if not its authority. This was a project, conceived in common with the famous Hebert, Momora, and Mazuel, and would have been aided in its execution by the daring Roufin, who at that time commanded a body of the arme revolutionaire.

How far Robespierre was apprised of or approved the scheme, does not appear; many shrewd observers of what was passing, seemed satisfied that it was to have been only a prelude "to the fwelling act" that was to follow, when the hero of the piece was to have been in full play. The majority of the convention faw through

ticipated their own danger, should it be carried into effect. They, therefore, without loss of time, annulled the proceedings already had in it, and declared all to be rebels who should persist therein. Chaumette appeared to put a good face on the correction. He told the commune, on its next meeting, that his proposition must be relinquished; for that the convention, with a voice paternal, though fevere, had flamped with nullity their former resolution, and that it became them, like dutiful children, to submit. Hebert, Momora, and Mazuel, were foon after accused as traitors, imprisoned, tried, and executed; but Chaumette furvived a short time longer, as his enemies thought it fafer to wear away by degrees the remaining popular partiality for him, before he should be struck at. He was taken up, however, on the 26th of March 1794, under a charge of conspiring, with the foregoing men, against the government, and guillotined on the 13th of April following, without the smallest effort, on the part of Robespierre, to fave him. Such is the gratitude and fuch the friendship of minds filled with univerfal philanthropy and the rights of man! That Chaumette and Robeinierie were closely linked together, is known to all who are not strangers to the transactions of that time; but when the latter had rifen to dictatorial power on the shoulders of the former, he kicked him, like a useless scaffold, from under his feet.

Chaumette said at the place of execution, that the revolution had inflamed his imagination, and at times intoxicated his brain, from the too free gratification of his vengeance for the personal injuries he had received. He faid also, that three inflances had come to light of his aristocratic and inveterate enemies attempting his life; and that a defire of reprifal, in which he conceived the fafety of the comm nwealth in a measure involved, made him feek all occasions for arrogating power; but that he never cherished an idea of possessing any permanent authority, not even of a secondary or subordinate nature. That the revolution intoxicated his brain, is doubtless true; but that he never aspired to permanent authority, is an infamous falsehood.

CHEMIN des Ronds, in fortification, the way of the rounds, or a space between the rampart and the low parapet under it, for the rounds to go about it.

CHEMISTRY,

Definition. TS a science, the object of which is to ascertain the ly practical chemists; and the most effential improveingredients that enter into the composition of bodies, to examine the nature of these ingredients, the manner in which they combine, and the properties refulting from their combination.

As an art, it has been in some measure coeval with the human race; for many of the most important branches of manufactures could not have been conducted without at least some knowledge of chemical combinations As a science, it can hardly be dated farther back than the middle of the 17th century; but fince that time it has advanced with a rapidity altogether unprecedented in the annals of philosophy. Newton laid its foundation; and fince his days an almost incredible number of the most distinguished names in Europe have enlisted under its banners. So rapid has this progress been, that though the article CHEMISTRY in the Encyclopadia Britannica was written only about ten years ago, the language and reasoning of chemistry have been fo greatly improved, and the number of facts have accumulated fo much, that we find ourselves under the necessity of tracing over again the very elements of the

Importance ery.

Indeed, if we confider the importance of chemistry, of chemif- we shall not be so much surprised at the ardour with which it has been cultivated. As a science, it is intimately connected with all the phenomena of nature; the causes of rain, snow, hail, dew, wind, carthquakes; even the changes of the feafons can never be explored with any chance of fuccess while we are ignorant of chemistry: and the vegetation of plants, and some of the most important functions of animals, have received all their illustration from the same source. No study can give us more exalted ideas of the wisdom and goodness of the Great First Cause than this, which shews us everywhere the most astonishing effects produced by the most simple though adequate means, and difplays to our view the great care which has everywhere been taken to fecure the comfort and happiness of every living creature. As an art, it is intimately connected with all our manufactures: The glafs-blower, the potter, the smith, and every other worker in metals, the tanner, the foap-maker, the dyer, the bleacher, are realments have been introduced into all these arts by the progress which chemistry has made as a science. Agriculture can only be improved rationally, and certainly by calling in the affistance of chemistry; and the advantages which medicine has derived from the same fource are too obvious to be pointed out.

It is evident from the definition of chemistry that it Arra must consist in a history of the sample substances which men enter into the composition of bodies, in an investigation of the manner in which these substances combine, and in a description of the properties of the compounds which they form. And this is the arrangement which we mean to purfue; referving to ourfelves, however, the liberty of deviating a little from it, whenever it may appear necessary for the fake of perspicuity. All our classifications are in fact artificial; nature does not know them, and will not submit to them. They are useful, however, as they enable us to learn a science sooner, and to remember it better; but if we mean to derive these advantages from them, we must renounce a rigid adherence to arbitrary definitions, which nature disclaims.

We shall begin by an account of the simplest bodies, and proceed gradually to those which are more compound. By fimple bodies, we do not mean what the ancient philosophers called the elements of bodies, but merely substances, which have not yet been decompounded. Very possibly the bodies which we reckon simple may be real compounds; but till this has actually been proved, we have no right to suppose it. Were we acquainted with all the elements of bodies, and with all the combinations of which these elements are capable, the science of chemistry would be as perfect as possible; but at present this is very far from being the case.

We shall divide this article into four parts. The first part shall treat of those bodies which are at present confidered as fimple; the fecond, of those bodies which are formed by the union of two fimple bodies, and which for want of a better word we shall call compound bodies; the third, of those bodies which are formed by the union of two compound bodies; and the fourth, of bodies fuch as they are presented to us by nature in the mineral, ve-

getable, and animal kingdoms.

OF SIMPLE BODIES. PART I.

fimple ho-

LL the bodies which are at present reckoned simple, because they have never been decompounded, may be reduced into fix classes.

1. Oxygen, 2. Simple combustibles,

4. Earths,

3. Metals,

5. Caloric, 6. Light.

These shall form the subjects of the fix following chapters.

CHAP. I. Of OXYGEN.

TAKE a quantity of nitre, or faltpetre as it is also called, and put it into a gun barrel A (fig. 1.), the touch-hole of which has been previously closed up with Met metal. This barrel is to be bent in fuch a manner, proc that while the close end, in which the nitre lies, is put (x) ! into the fire E, the open end may be plunged below the furface of the water, with which the vessel B is filled. At the same time, the glass jar D, previously filled with water, is placed on the support C, lying at the bottom of the vessel of water B, so as to be exactly over the open end of the gun barrel A. As soon as the nitre becomes hot, it emits a quantity of air, which iffuing from the end of the gun barrel, ascends to the top of the glass jar D, and gradually displaces all the water. The glass jar D then appears to be empty, but is in fact filled with air. It may then be removed in the following manner; Slide it away a little from the gun barrel and the support, and then dipping any flat dish into the water below it, raise it on it, and bear it away. The dish must be allowed to retain a quantity of water in it, (fee fig. 2.) Another jar may then be filled with air in the same manner; and this process may be continued either till the nitre ceases to give out air, or till as many jarfuls have been obtained as are required. This method of obtaining and confining air was first invented by Dr Mayow, and a terwards much improved by Dr Hales. All the airs obtained by this or any other process, or, to speak more properly, all the airs differing from the air of the atmosphere, have, in order to diftinguish them from it, been called gases, and this name we shall afterwards employ.

The gas which we have obtained by the above prothey cess was discovered by Dr Priestley on the 1st of Auand recie gust 1774, and called by him dephlogisticated air. Scheele of Sweden discovered it in 1775, without any previous knowledge of what Dr Priestley had done: he gave it the name of empyreal air. Condorcet, so conspicuous during the French revolution, gave it first the name of vital air; and Mr Lavoisier afterwards called it oxygen gas; a name which is now generally received, and

which we shall adopt.

Oxygen gas may be obtained likewise by the follow-

ing process:

Pr erties

ygen.

D (in fig. 3.) represents a wooden trough, the infide of which is lined with lead or tinned copper. AB is a shelf running along the inside of it, about three inches from the top. C is the cavity of the trough, which ought to be a foot deep. It is to be filled with water at least an inch above the shelf AB. In the body of the trough, which may be called the ciftern, the jars destined to hold gas are to be filled with water, and then to be lifted, and placed inverted upon the shelf at B, with their edges a little over it. This trough, which was invented by Dr Priestley, has been called by the French chemists the pneumato-chemical, or simply pneumatic apparatus, and is extremely useful in all experiments in which gases are concerned. Into the glass vessel E put a quantity of the black oxyd (A) of manganese in powder, and pour over it as much of that liquid which in commerce is called oil of vitriol, and in chemiltry fulphuric acid, as will fomewhat more than cover it. Then infert into the mouth of the veffel the glass tube F, so closely that no air can escape except through the tube. This may be done by covering the joining with a paste made of wheat flour and water, or any other lute, as substances used for similar purposes are called. The end of the tube C is then to be plunged into the pneumatic apparatus 1) and the jar G, previously filled with water, to he placed over it on the shelf. The whole apparatus being fixed in that fituation, the glass veffel E is to be heated by means of a lamp or a candle. A great quantity of oxygen gas rushes along the tube F, and fills the jar G. As foon as the jar is filled, it may be flid to another part of the shelf, and other jars substituted in its place, till as much gas has been obtained as is wanted.

1. Oxygen gas is colourless, and invisible like com-

mon air. Like it too, it is elastic, and capable of in- Oxygen. definite expansion and compression.

2. If a lighted taper be let down into a jar of oxygen Supports gas, it burns with fuch splendor that the eye can scarcely slame, bear the glare of light, and at the same time produces a much greater heat than when burning in common air. It is well known that a candle put into a well closed jar filled with common air is extinguished in a few seconds. This is the case also with a candle inclosed in oxygen gas; but it burns much longer in an equal quantity of that gas than of common air.

3. It was proved long ago by Boyle, that animals can- And life. not live without air, and by Mayow that they cannot breath the same air for any length of time without suffocation. Dr Priestley and several other philosophers have shewn us, that animals live much longer in the fame quantity of oxygen gas than of common air. Count Morozzo placed a number of sparrows, one after another, in a glass bell filled with common air, and in-

verted over water. The first sparrow lived 0 3 The fecond 0 3 The third

He filled the fame glass with oxygen gas, and repeated the experiment. The first sparrow lived

The	ninth	40				0	22	
The	tenth	-	-	-	-	0	21	

He then put in two together; the one died in 20 minutes, but the other lived an hour longer.

4. Atmospherical air contains about 27 parts in the Exists in hundred of oxygen gas. This was first discovered by be atmo-Scheele. It has been proved by a great number of ex-sphere. periments, that no substance will burn in common air previously deprived of all the oxygen gas which it contained; but combustibles burn with great splendor in oxygen gas, or in other gates to which oxygen gas has been added. Oxygen gas, then, is absolutely necessary for combustion.

5. It has been proved also, by many experiments, that no breathing animal can live for a moment in any air or gas which does not contain oxygen mixed with it. Oxygen gas then is absolutely necessary for respiration.

6. When substances are burnt in oxygen gas, or in any other gas containing oxygen, if the air be examined after the combustion, a great part of the oxygen will be found to have disappeared. If charcoal, for instance, be burnt in oxygen gas, there will be found, instead of part of the oxygen, another very different gas, known by the name of carbonic acid gas. Exactly the fame thing takes place when air is respired by animals; part of the oxygen gas disappears, and its place is occupied by fubflances possessed of very different properties. Oxygen

Dd2

use with bleachers and several other manufacturers.

(4) This substance shall be afterwards described. It is now very well known in Britain, as it is in common

Oxygen. gas then undergoes some change during combustion, as well as the bodies which have been burnt; and the same

observation applies also to respiration (B). 12

Its specific gravity.

7. The specific gravity of oxygen gas, as determined by Mr Kirwan*, is 0,00135, that of water being gisson, sect. i. 1,0000, as is always the case when specific gravity is mentioned absolutely. It is therefore 740 times lighter than the same bulk of water. Its weight to atmospherical air is as 1103 to 1000: 116 cubic inches of oxygen gas weigh 39,03 grains troy, 116 cubic inches of common air, 35,38 grains.

8. Oxygen is capable of combining with a great num-Affinity ex. ber of bodies, and forming compounds. As the combination of bodies is of the utmost importance in chemistry, before proceeding farther we shall attempt to explain it. When common falt is thrown into a vessel of pure water, it melts, and very foon foreads itself through the whole of the liquid, as any one may convince himself by the taste. In this case the salt is combined with the water, and cannot afterwards be separated by filtration or any other method merely mechanical. It may, however, by a very fimple process: Pour into the folution a quantity of spirit of wine, and the

whole of the falt inftantly falls to the bottom.

Why did the falt diffolve in water, and why did it fall to the bottom on pouring in spirit of wine? These questions were first answered by Sir Isaac Newton. There is a certain attraction between the particles of common falt and those of water, which causes them to unite together whenever they are presented to one another. There is an attraction also between the particles of water and of spirit of wine, which equally disposes them to unite, and this attraction is greater than that between the water and falt; the water therefore leaves the falt to unite with the spirit of wine, and the salt, being now unsupported, falls to the ground by its gravity. This power, which disposes the particles of different bodies to unite, was called by Newton attraction, by Bergman, elective attraction, and by many of the German and French chemists, affinity; and this last term we fhall employ, because the other two are rather general. All substances which are capable of combining together are faid to have an affinity for (c) each other: those substances, on the contrary, which do not unite, are faid to have no affinity for each other. Thus there is no affinity between water and oil. It appears from the instance of the common salt and spirit of wine, that substances differ in the degree of their affinity for other substances, since the spirit of wine displaced the falt and

united with the water. Spirit of wine therefore has a Oxyge stronger affinity for water than common falt has.

In 1719 Geoffroi invented a method of representing the different degrees of affinities in tables, which he called tables of affinity. His method consisted in placing the substances whose affinities were to be afcertained at the top of a column, and the substances with which it united below it, each in the order of its affinity; the fubstance which had the strongest affinity next it, and that which had the weakest farthest distant, and so of the rest. According to this method, the affinity of water for spirit of wine and common salt would be marked as follows:

WATER, Spirit of wine, Common falt.

This method has been univerfally adopted, and has contributed very much to the rapid progress of che-

We shall proceed therefore to give a table of the af-Affinite finities of oxygen.

OXYGEN,

Carbon, Zinc, Iron, Manganese, Hydrogen, Azot, Sulphur, Phosphorus, Cobalt, Nickel, Lead, Tin, Phosphorous acid. Copper, Bilmuth, Antimony, Mercury, Silver, Arfenic, Sulphurous acid, Nitrous gas, Gold, White oxyd of arfenic, Muriatic acid Oxyd of tin,

White

(B) Mayow had in the last century made confiderable progress towards the discovery of oxygen gas. He knew that only a part of the air supported combustion: This part he called particula igneo-aerea. He knew that this part was contained in nitre: "Pars nitri aerea nihil aliud quam particulæ ejus igneo-aereæ est." He adds, "At non est estimandum pabulum igneo aereum ipsum aerem esse, sed tantum partem ejus majus activam subtilemque. Quippe lucerna vitro inclusa expirat cum tamen copia aeris satis ampla in eodem continetur." He knew also that it was this part of the air which was useful in respiration. After mentioning seweral experiments to prove this, he adds, 46 Ex dictis certo constat animalia respirando particulas quasdam vitales easque elasticas ab aere haurire." See his Tractatus quinque Medico-Phylici, p. 12. and 106 .- He knew also that this part of the air was necessary to combustion : 66 Et tamen certo constat, particulas nitro-acreas non minus quam sulphureas ad ignem constandum necessareas esse." Ibid, p. 26.

(c) We are not certain that the phrase affinity for is warranted by classical authority; we have ventured, however, to use it, because, as the word affinity in this article fignifies a species of attraction, we thought it would be more perspicuous to put after it the preposition for, which usually follows the word attraction, than to or with,

which come after affinity when used in its ordinary acceptation.

rt I.

White oxyd of lead? Nitrous acid, White oxyd of manganefe, Water.

The reason of this order will appear when we treat of these various substances.

CHAP. II. Of SIMPLE COMBUSTIBLE BODIES.

imple By combustibles, we mean substances capable of combustibles, and by simple combustibles, bodies of that nature which have not yet been decompounded. These are only five in number, Sulphur, Phosphorus, Carbon, Hydrogen, and Azor. Were we to adhere strictly to our definition indeed, we should add all the metals; for they are also combustible, and have not yet been decompounded: But for the reasons formerly given, we shall venture to deviate a little from strict logic, and consider them afterwards as a distinct class of substances.

SECT. I. Of Sulphur.

SULPHUR, distinguished also in English by the name of brimstone, was known in the earliest ages. As it is found native in many parts of the world, it could not fail very soon to attract the attention of mankind. It was used by the ancients in medicine, and its sumes were employed in bleaching wool*.

Sulphur is a hard brittle fubstance, commonly of a yellow colour, without any fmell, and of a weak though

perties perceptible tafte.

Pliny,

16

XXXV.

lulphur

It is a non-conductor of electricity, and of course

becomes electric by friction.

If a confiderable piece of fulphur be exposed to a fudden though gentle heat, by holding it in the hand, bureroy, for instance, it breaks to pieces with a crackling noise.

Its specific gravity is 1,990.

When heated to the temperature of 185° of Fahrenheit, it melts and becomes very fluid. If the temperature be still farther increased, the sluidity diminishes; but when the sulphur is then carried from the fire and allowed to cool, it becomes as sluid as ever before it conbrake. geals ‡.

When sulphur is heated to the temperature of 170°, it rifes up in the form of a fine powder, which may be easily collected in a proper vessel. This powder is call-owers of ed flowers of sulphur. When substances sly off in this manner on the application of a moderate heat, they are called volatile; and the process itself, by which they are raised, is called volatilization.

Sulphur undergoes no change by being allowed to

remain exposed to the open air.

When thrown into water, it does not melt, as common falt does, but falls to the bottom, and remains there unchanged; it is therefore infoluble in water. If, however, it be poured, while in a ftate of fusion, into water, it assumes a red colour, and retains such a degree of softness, that it may be kneaded between the singers; Foureroy, but it loses this property in a few days*.

There are a great many bodies which, after being difable of folved in water or melted by heat, are capable of affuystalli- ming certain regular figures. If a quantity of common

falt, for inflance, be diffolved in water, and that fluid, by the application of a moderate heat, be made to fly off in the form of fleam; or, in other words, if the water be flowly evaporated, the falt will fall to the bottom of the veffel in cubes. These regular figures are called cryflals. Now fulphur is capable of cryflallizing. If it be melted, and as soon as its surface begins to congeal, the liquid sulphur beneath be poured out, the internal cavity will exhibit long needle shaped cryflallizing sulphur was contrived by Rouelle.

When sulphur is heated to the temperature of 302° Converted in the open air, it takes fire spontaneously, and burns by combuswith a pale blue flame, and at the same time emits a tion into an great quantity of fumes of a very strong suffocating acid. odour. When heated to the temperature of 570°, or a little higher, it burns with a bright white flame, and at the same time emits a vast quantity of sumes. If the heat be continued long enough, the fulphur burns all away without leaving any ashes or residuum. If the fumes be collected, they are found to confift entirely of fulphuric acid. By combustion, then, fulphur is converted into an acid. This fact was known feveral centuries ago, but no intelligible explanation was given of it till the time of Stahl. That chemist undertook the task; and founded on his experiments a theory fo exceedingly ingenious, and supported by such a vast number of facts, that it was in a very short time adopted with admiration by all the philosophic world, and contributed not a little to raife chemistry to that rank among the fciences from which the ridiculous pretenfions of the early chemists had excluded it.

According to Stahl, there is only one fubstance in Stahl's exnature capable of combustion, which therefore he called planation
Phlogiston; and all those bodies which can be set of this
on fire contain less or more of it. Combustion is merely the separation of this substance. Those bodies which
contain none of it are of course incombustible. All combustibles, except those which consist of pure phlogiston
(if there be any such), are composed of an incombustible
body and phlogiston united together. During combustion the phlogiston slies off, and the incombustible body
remains behind. Now when sulphur is burnt, the substance which remains is sulphuric acid, an incombustible
body. Sulphur therefore is composed of sulphuric acid

and phlogiston.

To establish this theory completely, it was necessary to shew that sulphur could be actually made by combining sulphuric acid and phlogiston; and this also Stahl undertook to perform. Sulphat of potass is a substance composed of sulphuric acid and potass (D), and charcoal is a combustible body, and therefore, according to the theory of Stahl, contains phlogiston: when burnt, it leaves a very inconsiderable residuum, and consequently contains hardly any thing else than phlogiston. He melted together in a crucible a mixture of potass and sulphat of potass, stirred into it one fourth part by weight of pounded charcoal, covered the crucible with another inverted over it, and applied a strong heat to it. He then allowed it to cool, and examined its contents. The charcoal had disappeared, and there only remained in the crucible a mixture of potass and sulphur combined

(D) The nature of potass shall afterwards be explained. It is the potash well known in commerce in a state of purity.

refiduum of the charcoal. Now there were only three fubstances in the crucible at first, potass, sulphuric acid, and charcoal: two of these have disappeared, and fulphur has been found in their place. Sulphur then must have been formed by the combination of these two. But charcoal confifts of phlogiston and a very small re-The fulfiduum, which is still found in the crucible. phur then must have been formed by the combination of sulphuric acid and phlogiston. This simple and luminous explanation appeared fo fatisfactory, that the composition of fulphur was long considered as one of the best demonstrated truths in chemistry.

Unsatisfactory.

There are two facts, however, which Stahl either did not know or did not fufficiently attend to, neither of which were accounted for by his theory. The first is, that fulphur will not burn if air be completely excluded; the second, that sulphuric acid is heavier than the

fulphur from which it was produced.

To account for these, or facts similar to these, succeeding chemists refined upon the theory of Stahl, deprived his phlogiston of gravity, and even assigned it a principle of levity. Still, however, the necessity of the contact of air remained unexplained. At last Mr Lavoisier, who had already distinguished himself by the extensiveness of his views, the accuracy of his experiments, and the precision of his reasoning, undertook the examination of this subject, and his experiments were pub-

lished in the Memoirs of the Academy of Sciences for Real expla-1777. He put a quantity of fulphur into a large glass nation by veffel filled with air, which he inverted into another vef-Lavoisier. fel containing mercury, and then fet fire to the sulphur by means of a burning glass. It emitted a blue slame, and gave out thick vapours, but was very foon extinguished, and could not be again kindled. There was, however, a little fulphuric acid formed, which was a good deal heavier than the fulphur which had disappeared; there was also a diminution in the air of the restel proportional to this increase of weight. The fulphur, therefore, during its conversion into an acid, must have absorbed part of the air. He then put a quantity of fulphuret of iron, which confifts of fulphur and iron combined together, into a glass vessel full of air, which he inverted over water (E). The quantity of air in the vessel continued diminishing for eighteen days, as was evident from the afcent of the water to occupy the fpace which it had left; but after that period no farther diminution took place. On examining the sulphuret, it was found somewhat heavier than when first introduced into the veffel, and the air of the veffel wanted precifely the same weight. Now this air had lost all its oxygen; all the oxygen of the air in the vessel must therefore have entered into the sulphuret. Part of the sulphur was converted into fulphuric acid; and as all the rest of the fulphuret was unchanged, the whole of the increase of weight must have been owing to something which had entered into that part of the fulphur which was converted into acid. This fomething we know was oxygen. Sulphuric acid therefore must be compofed of fulphur and oxygen; for as the original weight of the whole contents of the veffel remained exactly the

Sulphur. together, and of a darker colour than usual, from the fame, there was not the smallest reason to suppose that Sulphur

any fubiliance had left the sulphur.

It is impossible, then, that fulphur can be composed of fulphuric acid and phlogiston, as Stahl supposed; fince fulphur itself enters as a part into the composition of that acid. There must therefore have been some want of accuracy in the experiment by which Stahl proved the composition of sulphur, or at least some fallacy in his reasonings; for it is impossible that two contradictory facts can both be true. Upon examining the potafs and fulphur produced by Stahl's experiment, we find them to be confiderably lighter than the charcoal, fulphuric acid, and potass originally employed. Something therefore has made its escape during the application of the heat. And if the experiment be conducted in a close vessel, with a pneumatic apparatus attached to it, a quantity of gas will be obtained exactly equal to the weight which the substances operated on have loft; and this weight confiderably exceeds that of all the charcoal employed. This gas is carbonic acid gas, which is composed of charcoal and oxygen, as will afterwards appear. We now perceive what passes in this experiment: Charcoal has a stronger affinity for oxygen at a high temperature than sulphur has. When charcoal therefore is presented to sulphuric acid in that temperature, the oxygen of the acid combines with it, they fly off in the form of carbonic acid gas, and the fulphur is left behind.

The combustion of fulphur, then, is nothing else than the act of its combination with oxygen; and, for any thing which we know to the contrary, it is a fimple

fubitance.

The affinities of fulphur, according to Bergman, are Affiniti fulphur as follows:

Lead, Tin, Silver, Mercury, Arfenic, Antimony, Iron, Fixed alkalies, Ammonia, Barytes, Lime, Magnesia, Phosphorus? Oils, Ether, Alcohol.

SECT. II. Of Phofphorus.

LET a quantity of bones be burnt, or, as it is term- protu ed in chemistry, calcined, till they cease to smoke, or of pho to give out any odour, and let them afterwards be re-rus. duced to a fine powder. Put this powder into a glass veffel, and pour fulphuric acid on it by little at a time, till farther additions do not cause any extrication of air bubbles (F). Dilute the mixture with a good deal of water, agitate it well, and keep it hot for some hours; then pais it through a filtre. Evaporate the liquid

⁽E) This experiment was first made by Scheele, but with a different view. (F) The copious emission of air bubbles is called in chemistry effervescence.

sphor"s flowly till a quantity of white powder falls to the bottom. This powder must be separated by filtration and thrown away. The evaporation is then to be refumed; and whenever any white powder appears, the filtration must be repeated in order to separate it. During the whole process, what remains on the filtre must be washed with pure water, and this water added to the liquor. The evaporation is to be continued till all the moilture disappears, and nothing but a dry mass remains. Put this mass into a crucible, and keep it melted in the fire till it ceases to exhale fulphureous odours; then pour it out. When cold it affumes the appearance of a brittle glass. Pound this glass in a mortar, and mix it with one-third by weight of charcoal dust. Put this mixture into an earthen ware retort, and apply a receiver containing a little water. Put the retort into a fand bath, and increase the fire till it becomes red hot. A substance then paffes into the receiver, which has the appearance of melted wax, and which congeals as it falls into the water of the receiver. This substance is phosphorus.

It was discovered by Brandt, a chemist of Hamburgh, about the year 1667, while he was employed in attempting to extract from human urine a liquid capable of con-

verting filver into gold*.

Kunkel, another German chemist, hearing of the dif-Telange de covery, was anxious to find out the process, and for that purpose affociated himself with a friend of his named Kraft. But the latter procured the secret from the discoverer; and expecting by means of it to acquire a fortune, refused to give any information to his affociate. Vexed at this treachery, Kunkel refolved to attempt the discovery himself; and though he knew only that phosphorus was obtained from urine, prosecuted the inquiry with fo much zeal, that he fucceeded, and has been deservedly considered as one of the disco-

Boyle likewise discovered phosphorus. Leibnitz inred Experi-deed affirms that Kraft taught Boyle the whole process, and Kraft declared the same thing to Stahl. furely the affertion of a dealer in fecrets, and one who had deceived his own friend, on which the whole of this flory is founded, cannot be put in competition with the affirmation of a man like Boyle, who was one of the honestest men, as well as greatest philosophers, of his age; and he positively assures us, that he made the discovery without being previously acquainted with the processt.

Gahn, a Swedish chemist, discovered, in 1769, that phosphorus was contained in bones ||, and Scheele (G) Bergman's very foon after invented a process for obtaining it from them. Phosphorus is now generally procured in that manner. The process described in the beginning of this fection is that of the Dijon academicians: it differs from that of Scheele only in a fingle particular.

Phosphorus, when pure, is of a clear, transparent, yellowish colour; but when kept some time in water, it

becomes opaque, and then has a great refemblance to Phosphorus white wax. Its confiftence is nearly that of wax: it may be cut with a knife or twifted to pieces with the fingers. It is infoluble in water. Its specific gravity is 1,714.

It melts at the temperature of 99°*, and even at 67° * Pelletier, It melts at the temperature of 99, and teth dark; Journal de it gives out a white smoke, and is luminous in the dark; Physique, that is to fay, it suffers a flow combustion: so that it xxxv. 380. can only be prevented from taking fire by keeping it in a very low temperature, or by allowing it to remain always plunged in water. If air be excluded, it evaporates at 219°, and boils at 554° †. When heated to † Ibid. 381, 122°(H), it burns with a very bright flame, and gives Converted out a great quantity of white smoke, which is luminous by combusin the dark; at the same time it emits an odour which tion has some resemblance to that of garlic. It leaves no refiduum; but when the white smoke is collected, it is found to be an acid. Stahl considered this acid as the muriatic (1). According to him, phosphorus was composed of muriatic acid and phlogiston, and the combustion of it was merely the separation of phlogiston. He even declared, that to make phosphorus, nothing more was necessary than to combine muriatic acid and phlogiston; and that this composition was as easily accomt Three Huna plished as that of fulphur itself ‡.

dred Experia These affertions gained implicit credit; and the composition and nature of phosphorus were considered as completely understood, till Margraf of Berlin published his experiments in the year 1743. That great man, one of those illustrious philosophers who have contributed fo much to the rapid increase of the science, distinguished equally for the ingenuity of his experiments and the clearness of his reasoning, attempted to produce phosphorus by combining together phlogiston and muriatic acid; but though he varied his process a thoufand ways, prefented the acid in many different states, and employed a variety of substances to furnish phlogifton, all his attempts failed, and he was obliged to give up the combination as impracticable. On examining Into phofthe acid produced during the combustion of phospho phosic acid, rus, he found that its properties were very different from those of muriatic acid. It was therefore a distinct substance. The name of phosphoric acid was given to it; and it was concluded that phosphorus was composed of this acid united to phlogiston.

But it was observed in 1772 by Morveau*, that * Digress. phosphoric acid was heavier than the phosphorus from p 253. which it was produced (k); and Boyle had long before shewn that phosphorus would not burn except when in contact with air. These facts were sufficient to prove the inaccuracy of the theory concerning the composition of phosphorus; but they remained themselves unaccounted for, till Lavoisier published those celebrated experiments, which threw fo much light on the nature and composition of acids.

He exhausted a glass globe of air by means of an air-

(G) Crell, in his life of Scheele, informs us, that Scheele was him self the discoverer of the fact. This, he says, clearly appears from a printed letter of Scheele to Gahn, who was before looked upon as the discoverer. See Crell's Annals, English Trans. I. 17.

He fet fire to the phosphorus by means of a burning glass. The combustion was extremely rapid, accompanied by a bright flame and much heat. Large quantities of white flakes attached themselves to the inner surface of the globe, and rendered it opaque; and these at last became so abundant, that notwithstanding the constant supply of oxygen gas, the phosphorus was extinguished. The globe, after being allowed to cool, was again weighed before it was opened. The quantity of oxygen employed during the experiment was afcertained, and the phosphorus, which still remained unchanged, accurately weighed. The white flakes, which were nothing else than pure phosphoric acid, were found exactly equal to the weights of the phosphorus and oxygen, which had disappeared during the process. Phosphoric acid therefore must have been formed by photpherus the combination of these two bodies; for the absolute weight of all the substances together was the same before and after the process *. It is impossible then that gen * Lavoisier's phosphorus can be composed of phosphoric acid and phlogiston, as phosphorus itself enters into the compofition of that acid (L).

Thus the combustion of phosphorus, like that of fulphur, is nothing else than its combination with oxygen: for during the process no new substance appears except the acid, accompanied indeed with much heat and

light.

Phof. horus con bines with ful-

Which is

with xy-

chap. v.

Phosphorus combines readily with sulphur, as Margraf discovered during his experiments on phosphorus. This combination was afterwards examined by Mr Pelletier. The two fubstances are capable of being mixed in different proportions. Seventy-two grains of phofphorus and nine of fulphur, when heated in about four ounces of water, melt with a gentle heat. The compound remains fluid till it be cooled down to 77°, and then becomes folid. These substances were combined in the same manner in the following proportions:

Phosphor. Sulphur	congeals at	59°
Phofphor. Sulphur	at	50°
Phosphor. Sulphur	at	410
Phosphor. Sulphur	at	99°

Phosphorus and sulphur may be combined also by melting them together without any water; but the combination takes place fo rapidly, that they are apt to rush out of the vessel if the heat be not exceedingly mo-

The affinities of phosphorus have not yet been afcer-

SECT. III. Of Carbon.

IF a piece of wood be put into a crucible, well covered with fand, and kept red hot for some time, it is converted into a black shining brittle substance, without either taste or smell, well known under the name of charcoal. This substance contains always mixed with it several earthy and saline particles. When freed from these impurities it is called carbon.

Charcoal is infoluble in water. It is not affected (pro Propert vided that all air be excluded) by the most violent heat of carbo which can be applied, excepting only that it is rendered

much harder.

New-made charcoal abforbs moisture with avidity. When heated to a certain temperature, it absorbs air copiously. La Metherie plunged a piece of burning charcoal into mercury, in order to extinguish it, and introduced it immediately after into a glass veffel filled with common air. The charcoal absorbed four times its bulk of air. On plunging the charcoal in water, one-fifth of this air was disengaged. This air, on being examined, was found to contain a much smaller quantity of oxygen than atmospherical air does. He extinguished another piece of charcoal in the same manner, and then introduced it into a veffel filled with oxygen gas. The quantity of oxygen gas absorbed amounted to eight times the bulk of the charcoal; a fourth part of it was difengaged on plunging the charcoal into water*. It appears from the experiments of Sennebier, * Journ that charcoal when exposed to the atmosphere absorbs Phys. xx oxygen gas in preference to azot; as the other portion 309. of common air is called.

When heated to the temperature of 370°‡, it takes 261. fire, and, provided it has been previously freed from the More earths and falts which it generally contains, it burns thod. ar without leaving any refiduum. If this combustion be Affinité. performed in close veffels filled with oxygen gas instead of common air, part of the charcoal and oxygen difap-Convert pear, and in their room is found a particular gas exactly cid. equal to them in weight. This gas has the properties of an acid, and is therefore called carbonic acid gas. Mr Lavoisier, to whom we are indebted for this discovery, ascertained, by a number of very accurate experiments, that this gas was composed of about 28 parts of carbon and 72 of oxygen ||.

Carbon is susceptible of crystallization. In that state cad. 178 it is called diamond. The figure of the diamond varies p. 448. confiderably; but most commonly it is a hexagonal prism 33 terminated by a fix fided pyramid. When pure it is co-of cyfla lourless and transparent. Its specific gravity is from zation. 3,44 to 3,55. It is one of the hardest substances in nature; and as it is not affected by a confiderable heat, it was for many ages confidered as incombustible. Sir Ifaac Newton, observing that combustibles refracted light more powerfully than other bodies, and that the diamond possessed this property in great perfection, suf-

(L) The quantity of phosphorus consumed was 45 grains The quantity of oxygen gas 69,375

Weight of the phosphoric acid produced 114,375 Phosphoric acid therefore is composed of 100 parts phosphorus and 154 oxygen.

thon. pected, from that circumstance, that it was capable of combustion. This fingular conjecture was verified in 1694 by the Florentine academicians, in the presence of Cosmo III. grand duke of Tuscany. By means of a burning-glass, they destroyed several diamonds. Francis I. emperor of Germany, afterwards witneffed the destruction of several more in the heat of a furnace. These experiments were repeated by Rouelle, Macquer, and D'Arcet, who proved that the diamond was not merely evaporated, but actually burnt, and that if air was excluded it underwent no change.

No attempt, however, was made to ascertain the product, till Lavoisier undertonk a series of experiments for that purpose in 1772. He obtained carbonic acid gas. It might be concluded from these experiments, that the diamond contains carbon; but it was referved for Mr Tennant to show that it consisted entirely of that sub-

Then it

nms dia-

Into a tube of gold, having one end closed and a glass tube adapted to the other to collect the product, that gentleman put 2½ grains of diamonds and a quarter of an ounce of nitre (M). This tube was heated flowly; the confequence of which was, that great part of the nitric acid passed off before the diamond took fire, and by that means almost the whole of the carbonic acid formed during the combustion of the diamond remained in the potals, for which it has a strong affinity. To ascertain the quantity of this carbonic acid, he disfolved the potals in water, and added to the folution another falt composed of muriatic acid and lime. Muriatic acid has a stronger affinity for potass than for lime; it therefore combines with the potals, and at the same time the lime and carbonic acid unite and fall to the bottom of the vessel, because they are nearly insoluble in water. He decanted off the liquor, and put the lime which contained the carbonic acid gas into a glass globe, having a tube annexed to it. This globe and tube he then filled with mercury, and inverted into a veffel containing the fame fluid. The lime by that means occupied the very top of the tube. It now remained to separate the carbonic acid from the lime, which may be done by mixing it with any acid, as almost every other acid has a stronger affinity for lime than carbonic acid has. Accordingly on introducing muriatic acid, 10,3 ounce measures of carbonic acid gas, or nearly 9,166 grains, were separated. But, according to the experiments of Lavoisier, this gas is composed of 72 parts of oxygen and 28 of carbon; 9,166 grains therefore contain 2,56 grains of carbon, which is almost precisely the weight of the diamond consumed It follows, therefore, that it was composed of pure carbon *. 'The difficulty of burning the diamond is owing entirely to its hardness. Messrs Morveau and Tennant rendered common charcoal fo hard by exposing it for some time to a violent fire in close vessels, that it lost much of its natural tendency to combustion, and endured even a red heat without catching fire +.

Charcoal possesses a number of singular properties,

Suppl. Vol. I. Part I.

which render it of confiderable importance. It is in- Hydrogen. capable of putrifying or rotting like wood, and is not therefore liable to decay through age. This property has been long known. It was customary among the ancients to char the outfide of those stakes which were to be driven into the ground or placed in water, in order to preserve the wood from spoiling. New made cliarcoal, by being rolled up in cloths which have contracted a difagreeable odour, effectually destroys it. It takes away the bad taint from meat beginning to putrify, by being boiled along with it. It is perhaps the best teeth powder known. Mr Lowitz of Petersburgh has shown, that it may be used with advantage to purify a great variety of lubstances.

Carbon unites with a number of bodies, and forms Carburets. with them compounds known by the name of carburets.

Its affinities have not yet been ascertained,

Hydrogen, gen and oxygen gas be mixed together and kindled, they burn instantaneously, and produce an explosion like gunpowder. The fame effect follows when a mixture of hydrogen gas and atmospherical air is kindled, but the explosion is less violent. Hydrogen gas will not burn except in contact with oxygen gas, nor will it burn even in contact with oxygen gas, unless a red heat be applied to it. If 85 parts by weight of oxygen gas, and 15 of hydrogen gas, be mixed together, and fet on fire in a close vessel, they disappear, and in their place there is found a quantity of water exactly equal to them in weight. This water must be tion of wa-composed of these two gases; for it did not previously exist in the vessel, and no other substance except the gases was introduced. Water then is composed of oxygen and hydrogen; and the combustion of hydrogen is nothing elfe but the act of its combination with oxygen (o).

It had been supposed, in consequence of the experiments of Dr Priestley and several other philosophers, that when hydrogen gas was allowed to remain in contact with water, it was gradually decomposed, and converted into another gas; but Mr de Morveau*, Mr Chim. i. 754 Hassenfratz+, and Mr Libes+, have shewn, that it un-Chim.i. 192. dergoes no change, provided sufficient care be taken to

‡ Jour. de Pbys. xxxvi exclude every other gas.

Hydrogen gas dissolves fulphur, phosphorus, and carbon. The compounds are called fulphurated, phosphora-

Compoundsted, and carbonated bydrogen gas. of hydro-

1. Sulphurated hydrogen gas was first examined with attention by Scheele, who, together with Bergman, difcovered many of its properties. Mr Kirwan likewise published a very valuable paper on the same subject. If equal parts of fulphur and potafs be melted together in a covered crucible, they combine together, and form ted hydroa compound known by the name of fulphuret of potals, but formerly called, from its red colour, hepar sulphuris, or liver of fulphur. When this fubstance is moistened with water, it gives out a quantity of fulphurated hydrogen gas; hence this gas was at first called hepatic gas.

Mr Gengembie enclosed a bit of fulphur in a glass vessel filled with hydrogen gas, and melted the fulphur by means of a burning glass. A quantity of it disappeared, and the hydrogen assumed all the properties of hepatic gas. Hence it follows that this gas is merely

fulphur dissolved in hydrogen gas.

The easiest method of obtaining it is to pour an acid, the muriatic for instance, on a quantity of the fulphuret reduced to powder. An effervescence takes place, the gas is extricated, and may be collected by means of a pneumatic apparatus. The theory of this emission is obvious. The fulphur is gradually converted into fulphuric acid, by decomposing the water, which is always united with acids, and feizing its oxygen: the hydrogen of the water is thus fet at liberty; it affumes the gaseous form, and at the same time dissolves part of the remaining fulphur, for which it has a con- Hydroger fiderable affinity.

The specific gravity of sulphurated hydrogen gas is 0,00135*; it is to common air as 1106 to 1000.

It has a very fetid odour, precifely fimilar to that on Phlogistic emitted by rotten eggs, which indeed is owing to the feet. It. emission of the very same gas.

It is not more respirable than hydrogen gas. When fet on fire, in contact with oxygen gas, it burns with a light blue flame, without exploding, and at the same time a quantity of fulphur is deposited. The combustion of this gas, then, is merely the union of its hydrogen, and perhaps part of its fulphur, with oxygen.

This gas turns fyrup of violets to a green colour * . * Fourcroy It does not feem capable of existing in atmospherical art. Sulphi air without decomposition; for the moment it comes into contact with oxygen gas, fulphur is deposited +.

2. Phosphorated hydrogen gas was discovered by Mr Gengembre in 1783, and by Mr Kirwan some time after hydrogen the hydrogen gas was discovered by Mr Hosphorated ter, before he became acquainted with the experiments gen gas, of that gentleman. It may be procured by mixing phosphorus with potafs diffolved in water, and applying a boiling heat to the folution. The phofphorus is gradually converted into an acid by decomposing the water, and uniting with its oxygen. The hydrogen affumes the form of a gas, and flies off after diffolving a little of the phosphorus. This gas may be collected by means of a pneumatic apparatus.

Phosphorated hydrogen gas has a smell refembling that of putrid fish. When mixed with oxygen gas or common air, it becomes luminous; and on the application of the smallest heat, it burns with astonishing rapidity. ‡. The products are water and phosphoric acid. ‡ Kirwan, The combustion of this gas therefore is nothing else than the union of its phosphorus and hydrogen with oxygen, attended by an emission of heat and light.

Phosphorated hydrogen gas may also be formed by introducing a bit of phosphorus into a jar containing hydrogen gas; but care must be taken to make this gasas dry as possible; for its affinity with phosphorus is weakened in proportion to its moisture | .

3. Carbonated hydrogen gas arifes spontaneously in li, Nicholhot weather from marshes, but always mixed with seve-son's four-ral other gases. Several species of it have been lately nal, i. 445. discovered by the affociated Dutch chemists Bondt, Dieman, Van Trooftwyck, and Lauwcrenberg J. When & Ann. de 75 parts of sulphuric acid and 25 of spirit of wine are Chim. xxi. mixed together, a gas is extricated which suffers no al-48. teration from flanding over water. Its specific gravity Carbonate is 0,00111, or it is to common air as 909 to 1000. It Carbonau has a fetid odour, and burns with a strong compact gas. flame. When passed through fulphur it is converted into sulphurated hydrogen gas, and at the same time a quantity of carbon is deposited in the form of a fine powder; it must therefore be composed of carbon and hydrogen gas. When burnt, the product is carbonic

(o) The history of this great discovery, and the objections which have been made to it, we referve for the chapter which treats of Water, where they will be better understood than they could be at present. This subflance was called hydrogen by the French chemists, because it enters into the composition of water, from very awater, and ywou at I am born. Objections have been made to the propriety of the name, into which we shall not enter. It ought never to be forgotten, that Newton had long before, with a fagacity almost greater than human, conjectured, from its great refracting power, that water contained a combustible fubstance.

by ogen acid gas and water*. By making ether (r) pass thro' a red hot glass tube, another carbonated hydrogen gas was formed, the specific gravity of which was 0,00086. Spirit of wine, passed in the same manner, afforded a gas, the specific gravity of which was 0,00053, and which burned with a paler flame than the other two. These gases were found to contain from 80 to 74 parts of carbon, and from 20 to 26 of hydrogen. The first species was found to contain most carbon, and the last to contain least +.

The affinity of hydrogen gas for these three combus-

A ities of tibles is as follows:

Sulphur, Carbon, Phosphorus (Q).

Dr Austin found, that by repeatedly passing electric explosions through a small quantity of carbonated hydrogen gas, it was permanently dilated to more than twice its original bulk. He rightly concluded, that this remarkable expansion could only be owing to the evolution of hydrogen gas. On burning air thus ex-44 panded, he found that it required a greater quantity of compose oxygen than the same quantity of gas not dilated by electricity: An addition therefore had been made to the combustible matter; for the quantity of oxygen necessary to complete the combustion of any body, is always proportional to the quantity of that body. He concluded from these experiments, that he had decomposed the carbon which had been dissolved in the hydrogen gas; and that carbon was composed of hydrogen and azot (R), some of which was always found in the vessel after the dilated gas had been burnt by means of oxygen 1. If this conclusion be fairly drawn, we must expunge carbon from the list of simple substances,

of. lxxx. and henceforth confider it as a compound.

There was one circumftance which ought to have prevented Dr Austir from drawing this conclusion, at amined, seast till warranted by more decisive experiments. The quantity of combustible matter had been increased. Now, if the expansion of the carbonated hydrogen gas was owing merely to the decomposition of carbon, no fuch increase ought to have taken place, but rather the contrary; for the carbon, which was itself a combustible substance, was resolved into two ingredients, hydrogen and azot, only the first of which burnt on the addition of oxygen and the application of heat. Dr Auftin's experiments have been lately repeated by Mr William Henry with a great deal of accuracy *. He found, that the dilatation which Dr Austin describes actually and 1797 took place, but that it could not be carried beyond a a few days; but a confiderable refiduum of air still re-azot.

certain degree, a little more than twice the original bulk of the gas. Upon burning separately by means of oxygen, two equal portions of carbonated hydrogen gas, one of which had been expanded by electricity to double its original bulk, the other not, he found that each of them produced precifely the same quantity of carbonic acid gas. Both therefore contained the fame quantity of carbon; confequently no carbon had been decompounded by the electric shocks.

Mr Henry then suspected that the dilatation was ow- And found ing to the water which every gas contains in a larger or smaller quantity. To ascertain this, he endeavoure ful. to deprive the carbonated hydrogen gas of as much water as possible, by making it pass over very dry potass, which attracts water with avidity. Gas treated in this manner could only be expanded one-fixth of its bulk; but on admitting a drop or two of water, the expansion went on as usual. The substance decompounded by the electricity, then, was not the carbon, but the water in the carbonated hydrogen gas. Nor is it difficult to fee in what manner this decomposition is effected. Carbon at a high temperature has a greater affinity for oxygen than hydrogen has; for if the steam of water be made to pass over red hot charcoal, it is decomposed, and carbonic acid and hydrogen gas are formed. The electric explosion supplies the proper temperature; the carbon unites with the oxygen of the water, and forms carbonic acid; and the hydrogen, thus fet at liberty, occafions the dilation. Carbonic acid gas is absorbed with avidity by water: and when water was admitted into 709 measures of gas thus dilated, 100 measures were absorbed; a proof that carbonic acid gas was actually present. As to the azot which Dr Austin found in his dilated gas, it evidently proceeded from the admiffion of some atmospheric air, about 73 parts of which in the 100 confift of this gas: for Dr Austin's gas had flood long over water; and Drs Priestley and Higgins have shewn that air in such a situation always becomes impregnated with azot.

The affinities of hydrogen have not yet been after. Affinities of tained, but perhaps they are as follows: hydrogen.

Oxygen, Carbon,

Azot.

SECT. V. Of Azot.

IF a quantity of iron filings and fulphur, mixed together and moistened with water, be put into a glass vessel Method of full of air, it will abforb all the oxygen in the course of procuring

(P) Ether is a very volatile and fragrant liquid, obtained by mixing spirit of wine and acids, and distilling. It shall be afterwards described.

(Q) Sulphur decomposes carbonated hydrogen gas; therefore its affinity is greater than that of carbon. The Dutch chemists melted phosphorus in carbonated hydrogen gas, but no change was produced; therefore the

affinity of phosphorus is inferior to that of carbon.

⁽R) See next Section. - His theory was, that carbonated hydrogen gas was composed of hydrogen, and azot, and carbon of azot, and carbonated hydrogen gas, which comes nearly to the fame thing with regard to the elements of carbon. It is fingular enough, that though Dr Austin would not allow the presence of carbon in carbonated hydrogen gas, he actually decomposed it by melting sulphur in it: the sulphur combined with the hydrogen gas, and a quantity of carbon was precipitated. This experiment he relates without making any remarks upon it, and feems indeed not to have paid any attention to it. of caygen. Indoles carflica forrius tair! (says bt) a particular ges linit-arreis provenis.

49 Discovery of azct.

mains incapable of any farther diminution. This refidnum has obtained the appellation of azotic gas.

It was discovered in 1772 by Dr Rutherford, now professor of botany in the university of Edinburgh (s). Scheele procured it by the above process as early as 1776, and proved that it was a diffinct fluid. Mr Lavoifier afterwards proved the fame thing, without any previous knowledge of Scheele's discoveries.

The air of the atmosphere contains about ,73 parts of azotic gas; almost all the rest is oxygen gas. The eafiest method of procuring azotic gas is to put some sulphnret of potats into a glass vessel filled with air, and accurately closed, and then to apply heat to the fulphuret. All the oxygen is absorbed almost instantly. This * Nichol- method was first pointed out by Morveau*.

Mr Kirwan examined the specific gravity of azotic nal, i. 208. gas obtained by Scheele's process; it was 0,00120: it is therefore fomewhat lighter than the atmospheric | On Phlo air, it is to atmospheric air as 985 to 1000 ||.

gifton, § 1st. It tinges delicate blue colours slightly with

It tinges delicate blue colours flightly with green ‡. It is exceedingly noxious to animals; if they are obli-Its preper- ged to respire it, they drop down dead almost instantreason that a candle is extinguished in atmospherical air Chim. i. 45 as foon as the oxygen near it is confumed. Mr Goettling, indeed, published, in 1794, that phosphorus shone, and was converted into phosphoric acid, in pure azotic gas. Were this the case, it would not be true that no combustible burns in this gas; for the conversion of phofphorus into an acid, and even its shining, is an actual though flow combustion. Mr Goettling's experiments were foon after repeated by Drs Scherer and Jaeger, who found, that phosphorus does not shine in azotic gas when it is perfectly pure; and that therefore the gas on which Mr Goettling's experiments were made had contained a mixture of oxygen gas, owing principally to its having been only confined by water. Thefe refults were afterwards confirmed by Professor Lampadius and Professor Hildebrandt. It is therefore proved beyoud a doubt, that phosphorus does not burn in azotic gas, and that whenever it appears to do fo, there is + Nicholfon's always fome oxygen gas prefent +.

Journal, ii. Azotic gas is capable of diffolving pholphorus, as has been proved by the experiments of Fourcroy and

> It diffolves also a little carbon: for azotic gas obtained from animal fubitances, which contain a great

deal of azot, when confined long in jars, deposits on the fides of them a black matter which has the properties

Fources These two solutions the properties of which have not Ann. de yet been accurately examined, are called phosphorated Chim.i.4 and carbonated azotic gas.

Azotic gas is capable of combustion. Take a glass Producti tube, the diameter of which is about the fixth part of of nitric an inch; shut one of its ends with a cork, through the acid. middle of which paffes a fmall wire with a ball of metal at each end. Fill the tube with mercury, and then plunge its open end into a bason of that fluid. Throw up into the tube as much of a mixture, composed of 13 parts of azotic and 87 parts of oxygen gas, as will fill 3 inches. Through this gas make, by means of the wire in the cork, a number of electric explosions pals. The volume of gas gradually diminishes, and in its place there is found a quantity of nitrous acid. This acid, therefore, is composed of azot and oxygen: and these two fubstances are capable of combining, or, which is the fame thing, azotic gas is capable of combustion in the temperature produced by electricity, which we know Fourtroy, ly (T). No combustible will burn in it. This is the to be pretty high. The combustibility of azotic gas, and the nature of the product, was first discovered by Mr Cavendish, and communicated to the Royal Society on the 2d of June 1785 (v).

The affinities of azot are still unknown. It has never Attempt yet been decompounded, and must therefore, in the pre-to decom fent state of our knowledge, be considered as a simple pole azo substance. Dr Priestley, who obtained azotic gas at a very early period of his experiments, confidered it as a compound of oxygen gas and phlogiston, and for that reason gave it the name of phlogisticated air According to the theory of Stahl, which was then universally prevalent, he confidered combustion as merely the separation of phlogiston from the burning body. To this theory he made the following addition: Phlogifton is separated during combustion by means of chemical affinity: Air (that is, oxygen gas) has a strong affinity for phlogiston: Its presence is necessary during combustion, because it combines with the phlogiston as it separates from the combustible; and it even contributes by its affinity to produce that separation: The moment the air has combined with as much phlogifton as it can receive, or, to use a chemical term, the moment it is faturated with phlogiston, combustion neceffarily stops, because no more phlogiston can leave the combuf.

(s) See his thesis De Aere Mephitico, published in 1772 .- "Sed aer falubris et purus respiratione animali non modo ex parte sit mephiticus sed et aliam indolis sua mutationem inde patitur. Postquam enim omnis aer mephiticus (carbonic acid gas) ex eo, ope lixivii caustici secretus et abductus suerit, qui tamen restat nullo modo salubrior inde evadit; nam quamvis nullam ex aqua calcis præcipitationem faciat haud minus quam antea et flammam et vitam extinguit. Page 17.

"Aer qui per carbones ignitos folle adactus fuit, atque deinde ab omni aere mephitico (carbonic acid gas) expurgatus, malignus tamen adhuc reperitur et omnino fimilis est ei qui respiratione inquinatur. Immo ab experimentis patet, hanc folam esse aeris mutationem quæ inslammationi adscribi potest. Si enim accenditur materies quælibet quæ ex phlogisto et basi sixa atque simplici constat, aer inde natus ne minimum aeris mephitici quantitatem in se continere videtur. Sic aer in quo sulphur aut phosphorus urinæ combustus suit, licet maxime malignus, calcem tamen ex aqua minime præcipitat. Interdum quidem si ex phosphoro natus suerit, nubeculam aquæ calcis inducit sed tenuissimam, nec aeri mephitico attribuendam, sed potius acido illi quod in phosphoro inest, et quod, ut experimenta docuerunt, hoc fingulari dote pollet." Page 19.

(τ) Hence the name azot, given it by the French chemists, which signifies destructive to life, from a and ζων. u) It is remarkable enough, that the acidity of nitric acid was afcribed by Mayow, in 1674, to the presence of oxygen. Indoles caustica spiritus nitri (fays he) a particulis ejus igneo-aereis provenit. Tract. p. 19.

combustible (v): Air saturated with phlogiston is azo-This was a very ingenious theory, and, when Dr Priestley published it, exceedingly plausible. A great number of the most eminent chemists accordingly embraced it: But it was soon after discovered, that during combustion the quantity of air, instead of increating, as it ought to have done, had phlogiston been added to it, actually diminished both in volume and ef- weight. There was no proof, therefore, that during combustion any substance whatever combined with air, but rather the contrary. It was discovered also, that a quantity of air combined with the burning substance during combustion, as we have feen was the cafe with fulphur, phosphorus, carbon, and hydrogen; and that this air had the properties of oxygen gas. These discoveries entirely overthrew the evidence on which Dr Prieftley's theory was founded: accordingly, as no attempt to decompound azot has fucceeded, it has been given up by almost every chemist except Dr Priestley himself. Atmospheric air, as Scheele first proved, is compoled of about 27 parts of oxygen, and 73 of azotic gas. During combustion, the oxygen is abstracted and the azotic gas remains behind.

La Metherie made an attempt to prove that azot was composed of oxygen and carbon (w). He took a bit of burning charcoal, extinguished it in mercury, and then plunged it while hot into oxygen gas. On being plunged into water, one fourth of the gas was difengaged, and part of it was found to confift of azotic gas. From this he concluded, that he had formed azotic gas by combining oxygen and carbon: But it was proved by Mr Lavoisier, beyond the possibility of doubt, that oxygen and carbon form carbonic acid gas. They cannot then certainly form azot; for two contradictory facts cannot both be true. There must then have been fomething overlooked in the experiment. Indeed the experiment itself does not warrant the conclusion which De La Metherie drew from it. He did not ascertain whether the weight of the charcoal was diminished; and, befides, there was azot mixed with the oxygen gas which he employed, as he himself has informed us: And how was it possible for him to admit the charcoal into water without, at the fame time, admitting fome

atmospherical air?

WE have now described all the combustibles which are at prefent reckoned fimple, except the metals. We have found, that during combustion all of them combine with oxygen; that no part of them is disengaged, no part of them loft : we have therefore concluded, that the combustion of these substances is nothing else but the act of their uniting with oxygen. We have feen, however, that none of them, except phosphorus, was capable of uniting with oxygen at the common temperature of the atmosphere; that, in order to produce the union, heat was necessary, and that the degree of this heat was different for each. Hydrogen required a red heat, and azot a still greater. We have seen,

too, that during these combinations a quantity of heat Metals. and light escaped. Now why is heat necessary for these combinations? and whence come the heat and the light which we perceive during the combustion of these bodies? These questions are of the highest importance, and can only be answered by a particular investigation of the nature and properties of heat and light. investigation we shall attempt, as soon as we have defcribed the metals and earths, which form the subject of the two following chapters.

CHAP. III. Of METALS.

METALS may be considered as the great instruments Properties of all our improvements: Without them, many of the of metals, arts and sciences could hardly have existed. So sensible were the ancients of their great importance, that they raifed those persons who first discovered the art of working them to the rank of deities. In chemistry, they have always filled a conspicuous station: at one period the whole science was confined to them; and it may be faid to have owed its very existence to a rage for making and transmuting metals.

1. One of the most conspicuous properties of the metals is a particular brilliancy which they possess, and which has been called the metallic lustre. This proceeds from their reflecting much more light than any other body; a property which feems to depend partly on the closeness of their texture. This renders them peculiarly proper for mirrors, of which they always form the

balis.

2. They are absolutely opaque, or impervious to Opacity. light, even after they have been reduced to very thin plates. Silver leaf, for inflance, 100000 of an inch thick, does not permit the smallest ray of light to pass throught it. Gold, however, may be rendered transparent; for gold leaf, 280000 of an inch thick, transmits light of a lively green colour *. And it is not * Niebelimprobable that all the other metals, as Sir Ifaac Newton fon's Notes supposed, would become transparent, if they could be on Fourcroye reduced to a fufficient degree of thinnels. It is to this opacity that a part of the excellence of the metals, as mirrors, is owing; their brilliancy alone would not qualify them for that purpose.

3. They may be melted by the application of heat, Fufibility. and even then still retain their opacity. This property enables us to east them in molds, and then to give them any shape we please. In this manner many elegant iron utenfils are formed.

4. Their specific gravity is greater than that of any Gravity. other body hitherto discovered.

5. They are better conductors of electricity than any

6. But one of their most important properties is Malleabilimalleability, by which is meant the capacity of being ty. extended and flattened when struck with a hammer. This property enables us to give the metallic body any form we think proper, and thus renders it easy for us

(v) This ingenious theory was first conceived by Dr Rutherford, as appears from the following passage of his thesis. "Ex issdem etiam deducere licet quod aer ille malignus (azotic gas) componitur ex aere atmospherico cum phlogisto unito et quasi saturato. Atque idem consirmatur eo, quod aer qui metallorum calcinationi jam inferwit, et phlogiston ab iis abripuit, ejusdem plane sit indolis." De aere Mephitico, p. 20.

(w) Or rather of hydrogen, for he confidered carbon itself as a compound.

Metals. to convert them into the various instruments for which we have occasion. All metals do not possess this property; but it is remarkable that almost all those which were known to the ancients have it. Heat increases this property confiderably.

7. Another property which is also wanting in many Ductility of the metals, is ductility; by which we mean the capacity of being drawn out into wire by being forced through holes of various diameters. This property has by some been called tenacity; and it doubtless depends

upon the tenacity of the various metals.

8. When exposed to the action of heat and air, most Calcination of the metals lofe their lustre, and are converted into earthy like powders of different colours and properties, according to the metal and the degree of heat employed. Several of the metals even take fire when exposed to · a strong enough heat; and after combustion the residuum is found to be the very fame earthy-like fub. stance. If any of these calces, as they are called, be mixed with charcoal powder, and exposed to a strong heat in a proper vessel, it is changed again to the metal from which it was produced. From these phenomena Stahl's the Stahl concluded, that metals were composed of earth composition and phlogiston. He was of opinion, that there was only one primitive earth which not only formed the basis of the basis also of all the metals. He found, however, that it was impossible to combine any mere earth with phlogiston; and concluded, therefore, with Beccher, that there was another principle besides earth and phlogiston which entered into the composition of the metals. To this principle Beccher gave the name of mercurial earth, because, according to him, it existed most abundantly in mercury. This principle was supposed to be

very volatile, and therefore to fly off during calcination:

and some chemists even affirmed that it might be ob-

tained in the foot of those chimneys under which metals

have been calcined. A striking defect was soon perceived in this theory. Defective. The original metal may be again produced by heating its calx along with some other substance which contains - phlogiston: now, if the mercurial earth slies off during combustion, it cannot be necessary for the formation of complete metals, for they may be produced without it: if, on the contrary, it adheres always to the calk, there is no proof of its existence at all. Chemists, in consequence of these observations, found themselves obliged to discard the mercurial principle altogether, and to conclude, that metals were composed of earth only, united to phlogiston. But if this be really the case, how comes it that these two substances cannot be united by art? Henkel was the first who attempted to Improved folve this difficulty. According to him, earth and By Henkel phlogiston are substances of so opposite a nature, that it is exceedingly difficult, or rather it has been hitherto impossible, for us to commence their union; but after it has been once begun by nature, it is an easy matter to complete it. No calcination has hitherto deprived the metals of all their phlogiston; force still adheres to the calces. It is this remainder of phlogiston which renders it so easy to restore them to their metallic state.

Were the calcination to be continued long enough to M deprive them altogether of phlogiston, they would be reduced to the state of other earths; and then it would be equally difficult to convert them into metals, or, to use a chemical term, to reduce them. Accordingly we find, that the more completely a calx has been calcined, the more difficult is its reduction. This explanation was favourably received. But after the characteristic properties of the various earths had been ascertained, prove and the calces of metals were accurately examined, it was perceived that the calces differed in many particulars from all the earths, and from one another. To call them all the same substance, then, was to go much farther than either experiment or observation would warrant, or, rather, it was to declare open war against both experiment and observation. It was concluded, therefore, that each of the metals was composed of a peculiar earthy substance combined with phlogiston. For this great improvement in accuracy, chemistry is chiefly indebted to Bergman.

But there were feveral phenomena of calcination still which had all this time been unaccountably overlooked feet. The calces are all confiderably heavier than the metals from which they are obtained. Boyle had observed this circumstance, and had ascribed it to a quantity of all those substances known by the name of earths, but fire which, according to him, became fixed in the metal during the process I. But succeeding chemists paid | Fire little attention to it, or to the action of air, till Mr La-flame u voisier published his celebrated experiments on calcina-ed. tion, in the Memoirs of the Paris Academy for 1774. He put eight ounces of tin into a large glass retort, the point of which was drawn out into a very slender tube to admit of easy fusion. This retort was heated slowly till the tin began to melt, and then fealed hermetically. This heat was applied to expel some of the air from the retort; without which precaution it would have expanded and burst the vessel. The retort, which was capable of containing 250 cubic inches, was then weighed accurately, and placed again upon the fire. The tin foon melted, and a pellicle formed on its top, which Refuse was gradually converted into a grey powder, that funk by a little agitation to the bottom of the liquid metal: in short, the tin was partly converted into a calx. This process went on for three hours; after which the calcination stopped, and no farther, change could be produced on the metal. The retort was then taken from the fire, and found to be precifely of the same weight as before the operation. It is evident, then, that no new fubstance had been introduced, and that therefore the increased weight of calces cannot, as Boyle suppofed, be owing to the fixation of fire (x).

When the point of the retort was broken, the air rushed in with a hissing noise, and the weight of the retort was increased by ten grains. Ten grains of air, therefore, must have entered, and, consequently, precifely that quantity must have disappeared during the calcination. The metal and its calx being weighed, were found just ten grains heavier than before: therefore, the air which disappeared was absorbed by the metal: and as that part of the tin which remained in a metallic flate was unchanged, it is evident that this

(x) This experiment had been performed by Boyle with the same success. He had drawn a wrong conclusion from not attending to the state of the ar of the vessel. Shaw's Boyle, II. 394.

air must have united with the calk. The increase of gen than they have. This is the reason that charcoal. Metals. weight, then, which metals experience during calcination, is owing to their uniting with air (y). But all the air in the veffel was not absorbed, and yet the calcination would not go on. It is not the whole, then, but some particular part of the air which unites with the calces of metals. By the subsequent discoveries of Priestley, Scheele, and Lavoisier himself, it was ascertained, that the reliduum of the air, after calcination has been performed in it, is always pure azotic gas: It follows, therefore, that it is only the oxygen which combines with calces; and that a metallic calx is not a fimple substance, but a compound. Mr Lavoisier observed, that the weight of the calx was always equal to that of the metal employed, together with that of the oxygen absorbed. It became a question, then, Whether metals, during calcination, lost any substance, and, confequently, whether they contained any phlogiston? Mr Lavoisier accordingly proposed this question; and he answered it himself by a number of accurate experiments and ingenious observations. Metals cannot be calcined, excepting in contact with oxygen, and in proportion as they combine with it. Confequently they not only absorb oxygen during their calcination, but that absorption is absolutely necessary to their assuming the form of a calx. If the calx of mercury be heated in a retort, to which a pneumatic apparatus is attached, to the temperature of 1200°, it is converted into pure mercury; and, at the same time, a quantity of oxygen separates from it in a gaseous form. As this process was performed in a close vessel, no new substance could enter: The calx of mercuiy, then, was reduced to a metallic flate without phlogiston. The weights of the metal, and the oxygen gas, are together just equal to that of the calx; the calx of mercury, therefore, must be composed of mercury and oxygen; confequently, there is no reason whatever to suppose that mercury contains phlogiston. Its calcination is merely the act of uniting it with oxygen (z). The calces of lead, filver, and gold, may be decomposed exactly in the same manner; and Mr Van Marum, by means of his great electrical machine, decomposed also those of tin, zinc, and antimony, and refolved them into their respective metals and oxygen ||. The fame conclusions, therefore, 1785. must be drawn with respect to these metals. All the metallic calces may be decomposed by prefenting to

them substances which have a greater affinity for oxy-

powder is so efficacious in reducing them: and if they are mixed with it, and heated in a proper veffel, furnished with a pneumatic apparatus, it will be easy to discover what passes. During the reduction, a great deal of carbonic acid gas comes over, which, together with the metal, is equal to the weight of the calx and the charcoal: it must therefore contain all the ingredients; and we know that carbonic acid gas is composed of carbon and oxygen. During the process, then, the oxgen of the calx combined with the charcoal and the metal remained behind. It cannot be doubted, therefore, that all the metallic calces are composed of the entire metals combined with oxygen; and that calcination, like combustion, is merely the act of this combination. All metals, then, in the present state of chemistry, must be considered as simple substances; for they have never yet been decompounded.

The words calx and calcination are evidently impro-Oxyd and per, as they convey false ideas; we shall therefore af oxydation terwards employ, in stead of them, the words oxyd and what. oxydation, which were invented by the French chemists. A metallic oxyd fignifies a metal united with oxygen; and oxydation implies the act of that union.

Metals are capable of uniting with oxygen in different proportions, and, consequently, of forming each of them different oxyds. These are diffinguished from one another by their colour. One of the oxyds of iron, for instance, is of a green colour; it is therefore called the green oxyd; the other, which is brown, is called the

The metals at present amount to 21; only 11 of Number of which were known before the year 1730. Their names metals. are gold, filver, platinum, mercury, copper, iron, tin, lead, zinc, antimony, bifmuth, arfenic, cobalt, nickel, manganese, tungsten, molybdenum, uranium, tellurium, titanium, chromum.

The first eight of these were formerly called metals by way of eminence, because they are possessed either of malleability or ductility, or of both properties together; the rest were called femimetals, because they are brittle. But this distinction is now pretty generally laid afide; and, as Bergman observes, it ought to be so altogether, as it is founded on a false hypothesis, and conveys very erroneous ideas to the mind. The first four metals were formerly called noble or perfett metals, because their oxyds are reducible by the mere appli-

(v) It is remarkable that John Rey, a physician of Perigord, had ascribed it to this very cause as far back as the year 1630: But his writings had excited little attention, and had funk into oblivion, till after his opinion had been incontestibly proved by Lavoisier. Mayow also, in the year 1674, ascribed the increase of weight to the combination of metals with oxygen. Quippe vix concipi potest (says he), unde augmentum illud antimonii (calcinati) nisi a particulis nitro-aereis igneisque inter calcinandum FIXIS procedat. Tract. p. 28. Plane ut antimonii sixatio non tom a sulphuris ejus externi assumptione, quam particulis nuro-aereis, quibus stamma nitri abundat, EI INFIXIS provenire videatur. Ibid, p. 29.

⁽z) This experiment was performed by Mr Bayen in 1774. This philosopher perceived, earlier than Lavoisier, that all metals did not contain phlogiston. "Ces experiences (fays he) vont nous detromper. Je ne tiendrai plus le langage des disciples de Stahl, qui seront sorcés de restreindre la doctrine sur le phlogistique, ou d'avouer que les precipités mercurials, dont je parle, ne font pas des chaux metalliques, ou enfin qu'il y a des chaux qui peuvent se reduire sans le concours du phlogistique. Les experiences que j'ai faites me sorce de conclure que dans la chaux mercuriale dont je parle, le mercure doit son etat calcaire, non à la perte du phlogistique qu'il na pas effuyée, mais a sa combinaison intime avec le fluide elastique, dont le poids ajouté a celui du mercure est la seconde cause de l'augmentation de pesanteur qu'on observe dans les precipités que j'ai soumis a Pexamen." Jour. de Phys. 1774, pages 288, 295. It was in consequence of hearing Bayen's paper read thats Lavoisier was induced to turn his attention to the subject.

Gold.

cation of heat; the next four were imperfect metals, because their oxyds were thought not reducible without the addition of some combustible substance; but this distinction also is now very properly exploded.

SECT. I. Of Gold.

Properties of gold.

Gold feems to have been known from the very beginning of the world. Its properties and its fearcity have rendered it more valuable than any other metal.

It is of an orange red, or reddish yellow colour, and

has no perceptible tafte or fmell.

No other substance can be compared with it in ductility and malleability. It may be beaten out into leaves fo thin, that one grain of gold will cover 563 square inches. These leaves are only 182000 of an inch thick. But the gold leaf with which filver wire is covered has only Tof that thickness. An ounce of gold, upon filver wire, is capable of being extended more than 1300 miles in length.

Its tenacity is fuch, that a gold wire to of an inchin diameter, is capable of supporting a weight of 500

† Macquer's pounds without breaking ‡.

Its hardness is 6 (A); its specific gravity 19.3. It melts at 32° of Wedgewood's pyrometer (B). When melted, it assumes a bright bluish green colour. It expands in the act of fusion, and consequently contracts while becoming folid more than most metals; a circumstance which renders it less proper for casting into

It requires a very violent heat to volatilize it; it is therefore, to use a chemical term, exceedingly fixed. Boyle and Kunkel kept it for some months in a glasshouse furnace, and yet it underwent no change; nor did it lose any perceptible weight, after being exposed # Kirwan's for some hours to the utmost heat of Mr Parker's lens *. Miner. i.y2. Mr Lavoisier, however, observed, that a piece of silver,

held over gold melted by a fire blown by oxygen gas, which produces a much greater heat than common air, was fenfibly gilt: Part of the metal, then, must have

been volatilized.

Oxydation

of gold.

After fusion, it is capable of assuming a crystalline form. Tillet and Mongez obtained it in short qua-

drangular pyramidal crystals.

It is capable of combining with oxygen, and forming an oxyd of gold. There are two methods of producing this combination, the application of heat, and folution in acids. When it is exposed to a very violent heat in contact with air, gold abforbs oxygen. But the

temperature must be very high; fo high, indeed, that hardly any certain method of oxydating gold by heat' is known, except by electricity. When the electric explosion is transmitted through gold leaf placed between two plates of glass, or when a strong charge is made to fall on a gilded furface-in both cases the metal is oxydated, and assumes a purple colour. It has been faid also, that the same effect has been produced by a very violent fire; but few of the instances which have been adduced are well authenticated.

The other method of oxydating gold is much easier. For this purpose, equal parts of nitric and muriatic acids are mixed together (c), and poured upon gold; an effervescence takes place, the gold is gradually disfolved, and the liquid affumes a yellow colour. It is eafy to see in what manner this folution is produced. No metal is foluble in acids till it has been reduced to the flate of an oxyd. There is a strong affinity between the oxyd of gold and muriatic acid. The nitric acid furnishes oxygen to the gold, and the muriatic acid dissolves the oxyd as it forms. When nitric acid is deprived of the greater part of its oxygen, it affumes a gaseous form, and is then called nitrous gas. It is the emission of this gas which causes the effervescence. The oxyd of gold may be precipitated from the nitro-muriatic acid, by pouring in a little potafs diffolved in water, or, which is much better, a little lime, both of which have a stronger affinity for muriatic acid than the oxyd has. This oxyd is of a yellow

It is probable that gold is capable of two different degrees of oxydation, and of forming two different oxyds, the yellow and the purple: But neither the quantity of oxygen contained in these oxyds, nor the differences between them, have been accurately ascertained. The oxyds of gold may be decomposed in close vessels by the application of heat. The gold remains fixed, and the oxygen assumes the gaseous form. They may be decomposed, too, by all the substances which have a stronger affinity with oxygen than gold has. The affinities of the oxyds of gold, according to Bergman +, + Bern are as follows:

> Muriatic acid, Nitro-muriatic. Nitric, Sulphuric, Arfenic, Fluoric,

> > Tartarous,

Attras

Opufo.t.

(A) We have borrowed from Mr Kirwan the method of denoting the different degrees of hardness by figures, which we think a great improvement. These figures will be understood by Mr Kirwan's own explanation, which we here fubjoin.

3, Denotes the hardness of chalk.

4, A superior hardness, but yet what yields to the nail.

5, What will not yield to the nail, but eafily, and without grittiness, to the knife.

6, That which yields more difficultly to the knife. That which scarcely yields to the knife.

7, That which fearcely yields to the knite. 8, That which cannot be feraped by a knife, but does not give fire with fteel.

9, That which gives a few feeble sparks with steel.

10, That which gives plentiful lively sparks. Kirwan's Mineralogy, I. 38.

(B) According to the calculation of the Dijon academicians, it melts at 1298° Fahr.; according to Bergman, at 1301°.

(c) This mixture, from its property of diffolving gold, was formerly called aqua regia (for gold, among the alchymists, was the king of metals); it is now called nitro-muriatic acid.

Tartarous, Phosphoric, Sebacic, Prussic, Fixed alkali (D), Ammonia.

Gold is not changed either by air or water. It does not feem capable of combining either with fulphur or carbon. Mr Pelletier combined it with phosphorus, by melting together in a crucible half an ounce of gold and an ounce of phosphoric glass (E), furrounded with charcoal. The phosphuret of gold thus produced was brittle, whiter than gold, and had a crystallized appearance. It was composed of 23 parts of gold and one of phosphorus †. He formed the same compound by dropping small pieces of phosphorus into gold in surface.

Gold is also capable of combining with most of the metals Its affinities are placed, by Bergman, in the

following order:

Mercury, Copper, Silver, Lead, Bismuth, Tin, Antimony, Iron, Platinum, Zinc, Nickel, Arfenic, Cobalt, Manganese, Phosphorus? Sulphurets of alkalies.

SECT. II. Of Silver.

SILVER appears to have been known almost as early as gold. It is a metal of a shining white colour, without either taste or smell.

It is the most malleable and ductile of all metals except gold, and perhaps platinum. It can be reduced to leaves about 100000 of an inch thick, and drawn into wire much finer than a human hair.

Its tenacity is fuch, that a wire of filver, $\frac{\tau}{\tau \circ}$ of an inch in diameter, is capable of fultaining 270 pounds

r's without breaking ||.

Its hardness is 6,5 *. Its specific gravity, before hammering, is 10,474; after hammering, 10,510 ‡: for it is remarkable that the specific gravity of almost all the metals is increased by hammering.

It continues melted at 28° Wedgewood (F), but re-

, quires a greater heat to bring it to fusion +.

ii. The experiments of the French academicians have Suppl. Vol. I. Part I.

proved that it may be volatilized, but that it requires a very violent heat.

When cooled flowly, it assumes a crystalline form. Tillet and Mongez obtained it in quadrangular pyramidal crystals, both insulated and in groups.

Silver may be combined with oxygen, and converted oxyds of into an oxyd by exposure to a very violent heat. By this silver, method Junker partly converted it into a glass; and Macquer, by exposing it 20 times successively to the heat of a porcelain surnace, obtained a glass (G) of an olive green colour. The oxyd of silver may also be formed Macquer's by dissolving the metal in an acid, and precipitating it Dies. from its solution by potass, lime, &c.: for, during its solution, the metal becomes oxydated. Little is known at present concerning the oxyds of silver, nor whether there be more than two, the black and the blue. From the experiments of Wenzel and Bergman, it follows, that one oxyd of silver is composed of about 90 parts of metal and 10 of oxygen . The affinities of the Kirwan's oxyds, according to Bergman, are as sollows:

Muriatic acid,
Sebacic,
Oxalic,
Sulphuric,
Saccholactic,
Phofphoric,
Sulphurous,
Nitric,
Arfenic,
Fluoric,
Tartaric,
Citric,
Formic,
Lactic,

Acetous, Succinic, Pruffic, Carbonic,

Ammonia.

When filver is melted with fulphur in a low red heat, Sulphurez it combines with it and forms fulphuret of filver. It is of filver. very difficult to determine the proportion of the ingredients which enter into the composition of this substance, because there is an affinity between filver and its sulphuret, which dispotes them to combine together. The greatest quantity of sulphur which a given quantity of silver is capable of taking up is, according to Wenzel, \(\frac{1}{100}\) *. Sulphuret of silver is of a black or * Ibid. 492, very deep violet colour, brittle, and much more sulphur is volatilized, and the metal remains behind in a state of purity.

If one ounce of filver, one ounce of phosphoric glass, Phosphuret and two drams of charcoal, be mixed together, and of filver. heated in a crucible, phosphuret of filver is tormed. It

⁽D) Have the alkalis any affinity for the yellow oxyd? Is not their affinity confined to the purple oxyd alone? And does not this oxyd act as an acid?

⁽E) Phosphoric acid evaporated to dryness, and then fused.
(F) According to the Dijon academicians, it melts at 1044° Fahr.; according to Bergman, at 1000°.

⁽g) Metallic oxyds, after fusion, are called glass, because they acquire a good deal of resemblance, in some particulars, to common glass.

were crystallized. It breaks under the hammer, but may be cut with a knife. It is composed of four parts of filver and one of phosphorus. Heat decompoles it † Pelletier, by separating the phosphorus †. Pelletier has observed, that filver in fusion is capable of combining with more phosphorus than folid filver: for when phosphuret of filver is formed by projecting photphorus into melted filver, after the crucible is taken from the fire a quantity of phosphorus is emitted the moment the metal con-

\$ Ibid. xiii. 110.

geals t. Silver does not feem capable of combining with car-

Alloys of filver

Silver is capable of combining with gold, and forming an alloy (H) composed of one part of silver and five of gold. That this is the proportion of the ingredients, was discovered by Homberg. He kept equal parts of gold and filver in gentle fusion for a quarter of an hour, and found, on breaking the crucible, two masses the uppermost of which was pure filver, the undermost the whole gold combined with to of filver. Silver, however, may be mixed with gold in almost any proportion. But there is a great difference between the mixture of two fubstances and their chemical combination. Metals which melt nearly at the fame temperature, may be mixed from that very circumstance in any proportion; but fubiliances can combine chemically only in one proportion. This observation, which is certainly of importance, was first made, as far as we know, by Mr Keir ||. The alloy of filver and gold is of a greenish tion of Mac-colour; but its properties have not yet been accurately

art. Allay. examined. 78 Becomes tarnished by expofure.

Silver is not affected by water, nor by exposure to the air; but Mr Proust has remarked, that when long exposed in places frequented by men, as in churches, theatres, &c. it acquires a covering of a violet colour, which deprives it of its luftre and malleability. This covering, which forms a thin layer, can only be detached from the filver by bending it, or breaking it in pieces with a hammer. It was examined by Mr Prouft, and found to be fulphuret of filver. He accounts for this transition of the filver into a fulphuret, by supposing

Silver. is of a white colour, and appears granulated, or as it that a quantity of fulphur is conftantly formed and ex. Pa haled by living bodies *.

The affinities of filver, according to Bergman, are Chin as follows:

Lead, Copper, Mercury, Bismuth, Tin, Gold, Antimony, Iron, Manganese, Zinc, Arfenic, Nickel, Platinum, Sulphurets of alkalies. Sulphur, Phosphorus.

SECT. III. Of Platinum.

THE metals hitherto described have been known to mankind from the earliest ages, and have been always in high estimation on account of their beauty, scarcity, ductility, and indestructibility. But platinum, though perhaps inferior to them in none of these qualities, and certainly far superior in others, was unknown, as a dis-

tinct metal, before the year 1752 (1).

It has been found only in America, in Choco in Dife Peru, and in the mine of Santa Fe, near Carthagena. of p The workmen of these mines must no doubt have been nun early acquainted with it; but they feem to have paid very little attention to it. It was unknown in Europe till Mr Wood brought some of it from Jamaica in 1741. Soon after it was noticed by Don Antonio de Ulloa, a Spanish mathematician, who had accompanied the French academicians to Peru in their voyage to meafure a degree of the meridian. In the year 1752, it was examined by Scheffer of Sweden, and discovered by him to be a new metal, approaching very much to the nature of gold, and therefore called by him aurum album,

(H) Metals combined together are called alloys or allays.

(1) Father Cortinovis, indeed, has attempted to prove, that this metal was the electrum of the ancients. the Chemical Annals of Brugnatelli, 1790. That the electrum of the ancients was a metal, and a very valuable one, is evident from many of the ancient writers, particularly Homer. The following lines of Claudian are alone sufficient to prove it:

> Atria cinxit ebur, trabibus folidatur abenis Culmen et in celfas surgunt electra columnas. L. I. v. 164.

Pliny gives us an account of it in his Natural History. He informs us that it was a composition of filver and gold: and that by candle-light it shone with more splendor than silver. The ancients made cups, statues, and columns of it. Now, had it been our platinum, is it not rather extraordinary that no traces of a metal, which mult have been pretty abundant, should be perceptible in any part of the old continent?

As the passage of Pliny contains the fullest account of electrum to be found in any ancient author, we shall give it in his own words, that every one may have it in his power to judge whether or not the description will

apply to the platinum of the moderns.

"Omni auro inest argentum vario pondere.—Ubicunque quinta argenti portio est, electrum vocatur. Scrobes eæ reperiuntur in Canaliensi. Fit et cura electrum argento addito. Quod si quintam portionem excessit, incudibus non restitit. Et electro auctoritas, Homero teste, qui Menelai regiam auro, electro, argento, ebore fulgere tradit. Minervæ templum habet Lindos infulæ Rhodiorum in quo Helena facravit calicem ex electro.-- Electri natura est ad lucernarum lumina clarius argento splendere. Quod est nativum, et venena deprehendit. Namque discurrunt in calicibus arcus cœlestibus similes cum igneo kridore, et gemina ratione prædicunt."-Lib.xxxiii.cap.iv. allum, white gold. Soon after it was examined by Lewis, Margraf, Macquer and Beaumé, Morveau, Bergman, and many other illustrious chemists.

Platinum, when pure, is of a white colour like filver, but not so bright (k . It has no talte nor smell.

It is both ductile and malleable; but the precise degree has not yet been ascertained. It has been drawn into a wire of 1940 of an inch in diameter. This wire admitted of being flattened, and had more strength than a wire of filver or gold of the same fize ‡.

It is exceedingly difficult to fuse it. Macquer and Beaumé succeeded by means of a powerful burningglass. It melts more easily when mixed with other substances. Its fixity is still greater than its infusibility. If the strongest fires cannot melt it, much less can

they volatilize it.

Its hardness is 7,5 ||. Its specific gravity, after being hammered, is 23,000; fo that it is by far the heaviest

body known.

Some of the experiments which have been made on platinum feem to prove that it may be oxydated by the application of a violent heat. The oxyd of this metal may be eafily formed by diffolving platinum in nitromuriatic acid, and precipitating it by means of an earth or potals. The various oxyds of platinum have never yet been examined with accuracy. The one at present best known possesses, as Mr Berthollet has proved, the properties of an acid.

The fulphuret of platinum is unknown.

By mixing together an ounce of platinum, an ounce of phosphoric glass, and a dram of powdered charcoal, and applying a heat of about 32° Wedgewood, Mr Pelletier formed a phosphuret of platinum weighing more than an ounce. It was partly in the form of a button, and partly in cubic crystals. It was covered above by a blackish glass. It was of a filver white colour, very brittle, and hard enough to strike fire with steel When exposed to a fire strong enough to melt it, the phofphorus was difengaged, and burnt on the furface +.

He found also, that when phosphorus was projected on red hot platinum, the metal instantly fused and formed a phosphuret. As heat expels the phosphorus, Mr Pelletier has proposed this as an easy method of pu-

rifying platinum *.

Platinum does not feem capable of combining with

carbon.

It is not in the least affected by the action of water or air.

- 1. When gold and platinum are exposed to a strong heat, they combine, and form an alloy of a much whiter colour, but nearly as ductile as gold. The proportions of the ingredients are not known. When $\frac{1}{47}$ only of the alloy is platinum, the gold is scarcely altered in colour.
- 2. Whether filver and platinum combine chemically has not yet been properly ascertained. When fused together (for which a very strong heat is necessary), they form a mixture, not so ductile as silver, but harder and less white. The two metals are separated by keep-

ing them for some time in the state of fusion; the pla-Mercury. tinum finking to the bottom from its weight. circumstance would induce one to suppose that there is very little affinity between them.

SECT. IV. Of Mercury.

MERCURY, called also quickfilver, was known to the ancients, and feems to have been employed by them in gilding.

It is of a white colour, exactly like that of polished Properties filver. It has no taste, but acquires a slight odour when of mercury,

rubbed between the hands.

Its specific gravity is 13,568 ‡. ‡ Briffon.

It differs from all other metals in always existing, at the common temperature of the atmosphere, in a flate of fluidity. It freezes at -39° *; or, which is the same * See Macthing, it ceases to be a folid, and melts whenever it is nab's Expe placed in a temperature above -39°. It boils at the riments Phil, temperature of 600°. temperature of 600°.

From the experiments made on frozen mercury in Ruffia, Hudfon's Bay, and Britain, we know that this metal, when folid, is malleable; but the extreme difficulty of examining it in that state, on account of the lowness of the temperature, has rendered it hitherto impossible to ascertain the precise degree either of its malleability, ductility, or hardness.

Mercury is capable of combining with oxygen, and It forms of forming oxyds, differing from each other in the quan-three oxtity of oxygen which they contain. The oxyds of mercu-ds: ry, at present known, are the black, the yellow, and the red.

1. When mercury is agitated for some time in con-The black tact with oxygen gas, or atmospheric air, it is partly oxyd, converted into a greyish-black powder, and at the same time part of the oxygen disappears. This is the black oxyd of mercury. It is not known how much oxygen it contains, nor even whether the whole or the mercury which composes it be actually combined with oxygen.

2. The best way of forming the yellow oxyd is to Yellow dissolve mercury, either in boiling sulphuric acid or in oxyd, cold nitric acid. During its folution, it deprives these acids of just as much oxygen as is necessary to convert it into a yellow oxyd; and if potals or lime be afterwards added to the folution, it precipitates, and may be obtained pure by washing it with water. It is a bright yellow-coloured powder, which acts very powerfully as an emetic. From the observations of Bergman, it appears, that it is composed of about 95,8 parts of mercury, and 3,2 of oxygen *.

3. The red oxyd of mercury may be prepared, either Miner. ii. by distilling nitric acid off the metal repeatedly, or by 489 88 keeping mercury for a long time expoted to a heat fuffi-And red eient to evaporate it while it is in contact with air. oxyd. When formed by the first process, it was formerly called red precipita e; when by the last, precipitate per se. It is a beautiful red powder, or rather small red crystals, which have some escharotic qualities. When prepared by the fecond process, the heat must not be much below 600°, nor much above 800°, otherwise no union would take place; and it must be continued for some

(K) To this colour it owes its name. Plata, in Spanish, is filver; and platina, little filver, was the name first given to the metal Bergman changed that name into plainum, that the Latin names of all the metals might have the same termination and gender. It was, however, first called platinum by Linuæus.

489.

Mercury. weeks. From the experiments of Mr Kirwan, it appears to contain 92,6 parts of mercury and 7,4 of oxy-

Kirwan's gen †

These oxyds may be decomposed by the application of a heat amounting to 1200°. The oxygen sies off in the form of gas, and running mercury remains behind.

Their affinities.

'The affinities of the oxyds of mercury, according to Bergman, are as follows:

Sebacic acid, Muriatic. Oxalic, Succinic, Arfenic, Phosphoric, Sulphuric, Benzoic (L)? Saccholactic, Tartarous, Citric, Sulphurous, Nitric. Fluoric, Zoonic (M)? Acetous, Boracic, Pruffic, Carbonic.

Black fulphuret of mercury.

Red ful-

phuret.

When two parts of mercury and three parts of flowers of fulphur are triturated for fome time together, or when equal parts of mercury and melted fulphur are mixed together—they combine, and form a black powder, formerly called ethiops mineral, and now black fulphuret of mercury.

with a few drops of folution of potafs to moisten them,

When 300 grains of mercury and 68 of fulphur,

are triturated for some time in a porcelain cup by means of a glass pessele, black oxyd of mercury is produced. Add to this 160 grains of potass, dissolved in as much water. Heat the vessel containing the ingredients over the slame of a candle, and continue the trituration without interruption during the heating. In proportion as the liquid evaporates, add clear water from time to time, so that the oxyd may be constantly covered to the depth of near an inch. The trituration must be continued about two hours; at the end of which time the mixture begins to change from its original black colour to a brown, which usually happens when a large part of the sluid is evaporated. It then

fistence of a gelly, the red colour becomes more and more bright, with an incredible degree of quickness. The instant the colour has acquired its utmost beauty, the heat must be withdrawn, otherwise the red passes to a dirty brown. This red powder is the red fulphuret of mercury, called formerly cinnabar, and, when re-

duced to a fine powder, vermilion (N). The process

passes very rapidly to a red. No more water is to be

added; but the trituration is to be continued without

interruption. When the mass has acquired the con-

above described has been lately discovered by Mr Kir. Machoff, and is by far the simplest and cheapest mode of forming red sulphuret with which we are acquainted *.*Ni Count De Moussin Pouschin has discovered, that its pass Joan sing to a brown colour may be prevented by taking it from the fire as soon as it has acquired a red colour, and placing it for two or three days in a gentle heat, taking care to add a few drops of water, and to agitate the mixture from time to time. During this exposure, the red colour gradually improves, and at last becomes excellent. He discovered also, that when this sulphuret is exposed to a strong heat, it becomes instantly brown, and then passes into a dark violet; when taken from the fire it passes instantly to a beautiful carmine red †. † 18

The difference between these two sulphurets has never yet been ascertained. One would be apt to suspect at first that the black sulphuret consists of the real sulphuret of mercury combined with fulphur; the red, of the fulphuret of mercury combined with mercury, and that the real fulphuret of mercury was not yet accurately known. But it cannot be doubted that, during the formation of the red fulphuret, according to Kirchoff's process, there is an absorption of oxygen. The phenomena above described point out that almost incontestibly; and we observed, on attempting to repeat the experiment, that the black sulphuret, during its trituration, emitted fulphurated hydrogen gas. Perhaps, then, the mercury may be oxydated. We suspected at first that part of the sulphur might be converted into an acid; but on attemping an alteration of the process in consequence of that supposition, we could not succeed.

The red sulphuret of mercury is sound naturally in several parts of the world. It used to be prepared by forming a black sulphuret with three parts of sulphur and one of mercury, and then setting fire to it. Part of the sulphur is burnt, and there remains behind a violet-coloured body, which is powdered and put into a glass vessel, to the bottom of which a red heat is applied. A reddish brown substance sublimes, which is red sulphuret of mercury; but its colour is not nearly equal to that which is prepared by Kerchoff's process.

Mr Pelletier, after feveral unfuccessful attempts to pho form phosphuret of mercury, at last succeeded by distolatilling a mixture of red oxyd of mercury and phosphorus. Part of the phosphorus combined with the oxygen of the oxyd, and was converted into an acid; the rest combined with the mercury.

Phosphuret of mercury is of a black colour, of a pretty solid consistence, and capable of being cut with a knife. When exposed to the air, it exhaled vapours of phosphorus ||.

Mercury does not feem capable of combining with the carbon.

The combinations of mercury with the other metals Its are called amalgams.

1. The amalgam of gold forms very readily, because there is a very strong affinity between the two metals. If a bit of gold be dipped into mercury, its surface, by combining with mercury, becomes as white as silver.

The

(L) Benzoat of mercury is decomposed by sulphuric acid. Trommsdorf Ann. de Chim. xi. 316.
(M) Zoonic acid decomposes the acetite of mercury. Berthollet.

⁽N) The word vermilion is derived from the French word vermeil, which comes from vermiculus or vermiculum, names given in the middle ages to the kermes or coccus ilicis, well known as a red dye. Vermilion originally fignified the red dye of the kermes. See Beckmann's Hift. of Discoveries, II. 180.

fmall pieces of red hot gold into mercury. 'The proportions of the ingredients are not eafily determined, because the amalgam has an affinity both for the gold and the mercury; in consequence of which they appear to combine in any proportion. Most probably it is composed of two parts of gold and one of mercury. The combination is formed most readily in these proportions; and if too much mercury be added, it may be separated by filtration. The amalgam is of a white colour, and of the confishence of butter +. This amalgam crystallizes in quadrangular prisms; which crystals, according to the Dijon academicians, are compofed of fix parts of mercury and one of gold. It is

much uted in gilding.
2. The amalgam of filver is made in the fame manner. It forms dendritical cryftals, which, according to the Dijon academicians, contain eight parts of mercury and one of filver. Gellert was the first who remarked that its specific gravity was greater than that of mer-

cury, though that of filver be lefs.

3. Dr Lewis attempted to form an amalgam of platinum, but hardly succeeded, after a labour which lafted for feveral weeks. Mr Morveau succeeded by means of heat +. But a much more expeditious method has Thim xxiv. been lately discovered by Count Moussin Pouschin. He took a dram of the orange-coloured falt, composed of oxyd of platinum and ammonia (o), and triturated it with an equal weight of mercury in a mortar of chalcedony. In a few minutes the falt became brown, and afterwards acquired a greenish shade. The matter was reduced to a very fine powder. Another dram of mercury was added, and the trituration continued: The matter became grey. A third dram of mercury began to form an amalgam; and fix drams made the amalgam perfect. The whole operation scarce lasted 20 minutes. Mercury was added till it amounted to nine times the weight of the falt, and yet the amalgam continued very tenacious. It was eafily spread out under the pestle; it received the impression of the most delicate seals, and had a very close and brilliant grain. This amalgam is decomposed, and the mercury passes to the state of black oxyd by the simple contact of feveral of the metals and a great number of animal matters. This effect even takes place on rubbing it between the fingers *.

The affinities of mercury, as afcertained by the expc-

Affinities. riments of Morveau (P), are as follows:

Gold, Silver, Tin, Lead, Bismuth, Zinc, Copper, Antimony, Arlenic (Q), Iron.

SECT. V. Of Copper.

EXCEPT gold and filver, copper feems to have been

lercury. The easiest way of forming this amalgam is to throw more early known than any other metal. In the first Copper. ages of the world, before the method of working iron was discovered, copper was a principal ingredient in all domestic utenfils and instruments of war. Even during the Trojan war, as we learn from Homer, the combatants had no other armour but what was made of bronze, which is a mixture of copper and tin. The word copper is derived from the island of Cyprus, where it was first discovered, or at least wrought to any extent, by the Greeks.

Copper is of a pale red colour with a shade of yel- Properties low. Its taste is styptic and nauseous; and when rub- of copper, bed it emits a disagreeable smell. It possesses a considerable degree of malleability, though less than filver. Its tenacity is such, that a wire of $\frac{\tau}{\tau \odot}$ of an inch in diameter can fustain a weight of 299 to pounds without Macquer's

breaking +. Its hardness is 8 ‡. Its specific gravity, when not Dia. hammered, is 7,788; when wire-drawn, 8,878 ||. The Miner. ii. specific gravity of Japan copper is 9,000 *; that of 127 Swedish copper, 9,3243 T.

It melts at 27° Wedgewood; according to the cal- * Keir's Notes on culation of the Dijon academicians, at 14490 Fahrenheit. Macquer's When allowed to cool flowly, it assumes a crystalline Dies. form. The Abbé Mongez, to whom we owe many + Bergman, valuable experiments on the crystallization of metals, ii. 263. informs us, that these crystals are quadrangular pyramids, frequently inferted into one another.

When copper is heated red hot in contact with air, Brown it is foon covered with a brown earthy cruft, which may oxyd of be easily separated by hammering or by plunging the me-copper. tal into water. If the heat be continued, another feale of the same kind soon forms; and by continuing the process the whole metal may be converted into an earthy-like cruft, which is merely a combination of copper and oxygen, and is therefore called brown oxyd of copper. It is composed of about 84 parts of copper and 16 of Kirwan's

When copper is diffolved in fulphuric acid, and pre-Miner. ii. cipitated by means of lime, it falls in the form of a blue-487. coloured powder, which is the blue oxyd of copper. If Blue and this oxyd of copper be dried in the open air, it assumes green a green colour, and is then called the green oxyd of cop-oxyds. per. This last oxyd may also be produced by distilling a sufficient quantity of nitric acid off copper. Little fatisfactory is yet known with respect to these oxyds; it has not even been ascertained whether the blue and green be really two different oxyds, or whether the difference in colour be owing to some other cause. It is probable, however, that the green oxyd contains more oxygen than the blue; because the blue oxyd assumes a green colour when exposed for some time to the open air, during which it may be supposed to absorb oxygen. An experiment of Fourcroy proves incontestibly, that the brown oxyd contains less oxygen than the green. He converted the green oxyd into the brown by applying heat; and during the diffillation obtained oxygen gas ||. || Fourth

Tartarous,

* Schrickel

(o) Ammonia is an alkali hereafter to be described. It is often called, in English, hartshorn.

(P) We shall have occasion to confider these celebrated experiments afterwards.

⁽Q) These two are added from Bergman. Bergman places lead before tin, and zinc before bismuth.

Tartarous. Muriatic, Sulphuric, Saccholactic, Nitric, Sebacic, Arfenic, Phosphoric, Succinic, Fluoric. Citric, Formic, Lactic, Acetous, Boracic, Pruffic, Carbonic, Fixed alkalies, Ammonia, Fixed oils.

When copper is long exposed to the air, its surface pecomes covered over with a green crust, which is green oxyd of copper. This oxydation never penetrates beyond the furface.

Copper is not attacked by water at the boiling temperature; but if cold water be allowed to remain long on its furface, the metal becomes partly oxydated

Sulphur mixes readily with copper. The combination may be formed by mixing the ingredients together of copper. and applying a pretty strong heat. Sulphuret of copper is brittle, fofter than copper, of a black colour externally, and within of a leaden grey. It is composed, according to Kirwan's experiments, of 81 parts of copper

* Kirwan's and 19 of fulphur *.

Sulphuret

3.

Alloys of

copper.

Miner. il. Mr Pelletier formed phosphuret of copper by melting together one ounce of copper, one ounce of phosphoric Phosphuret glass, and one dram of charcoal. It was of a white of copper. colour. On exposure to the air, it lost its lustre and ‡ Ann. de became blackish ‡. Margraf was the first person that Chim. i. 74. formed this phosphuret. His method was to distil phosphorus and brown oxyd of copper together. It is formed most easily by projecting phosphorus into red hot copper. According to Pelletier, it contains 20 * Ibid. xiii. parts of phosphorus and 80 of copper *. I'his phofphuret is harder than iron: It is not ductile, and yet cannot easily be pulverised. Its specific gravity is 7,1220. ‡ Sage, It crystallizes in tetrahedral prisms ‡. Journ de Phys.

Journ de 1. Copper combines readily with gold when the two xxxviii. 468 metals are melted together. The compound is of a reddish colour, more fusible than gold, but less ductile. The proportions of the ingredients which form this alloy are not known; nor would it be easy to ascertain them, as the two metals are almost equally fulible. The current gold of this country is composed of 11 parts of

gold and one part of copper.

2. The alloy of copper and filver is made as eafily as that of gold, and the properties are equally unknown. It is harder and more fonorous than filver. The current filver coin of Britain is composed of 15 parts of filver and one of copper.

3. Platinum combines readily with copper. The alloy is much more fulible than platinum; it is ductile, hard, takes a fine polish, and is not liable to tarnish. This alloy has been employed with advantage for compoling the mirrors of reflecting telescopes.

4. The amalgam of copper cannot be formed by fimply mixing that metal with mercury, nor even by the application of heat; because the heat necessary to melt copper sublimes mercury. Dr Lewis has given us several processes for forming this amalgam. One of the fimplest is to triturate mercury with a quantity of common falt and verdigrile; a substance composed of oxyd of copper and vinegar. The theory of this process is not very obvious.

The affinities of copper are, according to Bergman, Itsaffinities,

as follows:

Gold, Silver, Arfenic, Iron, Manganefe, Zinc, Antimony, Platinum, Tin, Lead, Nickel, Bismuth, Cobalt, Mercury, Sulphuret of alkali, Sulphur, Phosphorus.

SECT VI. Of Iron.

IRON, the most abundant and most useful of all the Discovery metals, was neither known fo early, nor wrought fo of iron. eafily, as gold, filver, and copper. For its discovery we must have recourse to the nations of the east, among whom, indeed, almost all the arts and sciences first sprung up. The writings of Moses (who was born about 1635 years before Christ) furnish us with the amplest proof at how early a period it was known in Egypt and Phœnicia. He mentions furnaces for working iron t, ores from which it was extracted *; and t Deut. iv. tells us, that fwords ||, knives ¶, axes +, and tools for * Ibid. viii. cutting stones f, were then made of that metal. How 9 many ages before the birth of Moses iron must have | Numb. been discovered in these countries, we may perhaps con- *xxxv. 16. ceive, if we reflect, that the knowledge of iron was 17 brought over from Phrygia to Grecce by the Dactyli *, + Deut. who fettled in Crete during the reign of Minos I. about xviii. 5. 1431 years before Christ; yet during the Projan war, \$ Ibid.xxvii. which happened 200 years after that period, iron was * Hefiod, as in fuch high estimation, that Achilles proposed a ball quoted by of it as one of his prizes during the games which he Pliny, celebrated in honour of Patroclus (R). At that period lib. vii none of their weapons were formed of iron. Now if the Greeks in 200 years had made foolittle progress in an art which they learned from others, how long must

it have taken the Egyptians, Phrygians, Chalybes, or whatever nation first discovered the art of working iron, to have made that progress in it which we find they had

done in the days of Moses? 104 proper-

Iron, when fresh broken, is of a bluish grey colour. It has a styptic taste, and emits a smell when rubbed. It is malleable and ductile in every temperature; and

its malleability is increased in proportion as the temperature augments. Its tenacity is fuch, that an iron wire to of an inch in diameter fustains a weight of 450

Macquer's pounds without breaking *.

Its hardness is such, that it may be easily reduced to powder by the application of a file. Its specific gravity is 7,788. It is infufible in the strongest heats hitherto produced.

It is attracted by the magnet or loadstone, and is itfelf capable of becoming magnetic; but it retains this

property only for a very short time.

It is not hardened by being plunged into liquids while hot, nor foftened by being cooled flowly.

Iron combines with oxygen very readily. kindled in oxygen gas, it burns with great rapidity and fplendor, and is in this manner converted into an oxyd. It is converted into an oxyd also when surrounded by moift air, or when plunged in water; because it has a ftronger affinity for oxygen than hydrogen has, and is therefore capable of decomposing water.

Mr Proust has lately proved, that there are only two oxyds of iron, the green and the brown or red, and that all the other supposed oxyds are merely mixtures of these

two in various proportions +.

The green oxyd may be obtained by diffolving iron in Thim XXIII. 35. and Nifulphuric acid, and then precipitating it by potals. Journal, i. is a light, green-coloured, earthy-like substance, composed, as Mr Lavoisier has shewn, of 27 parts of oxyt Mem. A- gen, and 73 of iron ‡. When this oxyd is exposed to the air, it quickly absorbs more oxygen, and is converted into a brown powder, which is the brown oxyd. Mr Proust has proved that it contains 52 parts of iron and 48 of oxygen. This oxyd is well known under the name of rust of iron, which is generally, however, or perhaps always, combined with carbonic acid

The affinities of these oxyds, according to Bergman,

Iron unites readily with fulphur. Sulphuret of iron, Sulphuret; formerly called pyrites, is found ready formed in many parts of the world. It is not easy to determine the proportions of its ingredients, because it is capable of combining both with iron and fulphur, and confequently, if there happens to be any excess of either during its' formation, it takes it up. Perhaps the proportions are not far from equal parts of fulphur and of iron. It is of a pale yellow or brownish colour, and is capable of assuming a crystalline form. Its specific gravity is about 4,000. When placed upon the fire, it precipitates; and at a red heat lofes its yellow colour, and becomes of an iron grey, excepting its furface, which is of a bright red. It melts at 102° Wedgewood in a covered crucible into a bluish slag. somewhat porous internally ‡. When exposed to air and moisture, the Kirwan's fulphur, as happens in all fulphurets, gradually abforbs 76. oxygen, and is converted into an acid.

If iron filings and fulphur be mixed together, and formed into a paste with water, the sulphur decomposes the water, and absorbs oxygen so rapidly that the mixture takes fire, even though it be buried under ground. This phenomenon was first discovered by Homberg; and it is confidered as affording an explanation of the origin of volcanoes. The native fulphuret of iron has been observed more than once to take fire on being suddenly moistened with water.

Iron combines readily with phosphorus, and forms Phosphu-

phosphuret of iron; to which Bergman, who first disco-ret,

vered it, gave the name of fiderum.

There is a particular kind of iron, known by the name of cold short iron, because it is brittle when cold, though it be malleable when hot. Bergman was employed at Upfal in examining the cause of this property, while Meyer was occupied at Stetin with the same investigation; and both of them discovered, nearly at the fame time, that, by means of fulpliuric acid, a white powder could be separated from this kind of iron, which by the usual process they converted into a metal of a dark fleel grey, exceedingly brittle, and not very foluble in acids. Its specific gravity was 6,700; it was not so fusible as copper; and when combined with iron rendered it cold short. Both of them concluded that this fubflance was a new metal; and Bergman gave it the name of fiderum. But Klaproth foon after recol-lecting that the falt composed of phosphoric acid and iron bore a great resemblance to the white powder obtained from cold short iron, suspected the presence of phosphorie

Iron.

Beldocs,

point, he combined phosphoric acid and iron, and obtained, by heating it in a crucible along with charcoal powder (s), a fubstance exactly resembling the new metal. Meyer, when Klaproth communicated to him this discovery, informed him that he had already fatisfied himself, by a more accurate examination, that fiderum contained phosphoric acid. Soon after this, Scheele actually decomposed the white powder obtained from cold short iron, and thereby demonstrated, that it was composed of phosphoric acid and iron. The fiderum of Bergman, however, is composed of phosphorus and iron, the phosphoric acid being deprived of its oxygen during the reduction; or it is phosphuret of iron. It may be formed by fufing in a crucible an ounce of phofphoric glass, an ounce of iron, and half a dram of charcoal powder. It is very brittle, and appears white when broken. When exposed to a firong heat, it melts, and * Pelletier, the phosphorus is diffipated *. It may be formed also by melting together equal parts of phosphoric glass and iron-filings. Part of the iron combines with the oxygen of the phosphoric glass, and is vitrified; the rest forms the phosphuret, which finks to the bottom of the crucible. It may be formed also by dropping small bits of phofohorus into iron-filings heated red hot t. The proportions of the ingredients of this phosphuret have not yet been determined.

phosphoric acid in this new metal. To decide the

Iron likewife combines with carbon, and forms a And carburet of iron. carburet. Carburet of iron has been long known and used in the arts under the names of plumbago and black lead. It is of a dark iron grey or blue colour, and has fomething of a metallic lustre. It has a greafy feel, and blackens the fingers, or any other fubstance to which it is applied. It is found in many parts of the world, efpecially in England, where it is manufactured into pencils. It is not affected by the most violent heat as long as air is excluded, nor is it in the least altered by simple exposure to the air, or to water. Its nature was first investigated by Scheele; who proved, by a very ingenious analysis, that it could be converted almost wholly into carbonic acid gas, and that the fmall refiduum was It follows from this analysis, that it is composed of carbon and iron; for the carbon during its combustion had been converted into carbonic acid gas. By the subsequent experiments of Pelletier and other French chemists, it has been shewn to consist nearly of nine parts of carbon to one of iron.

There are a great many varieties of iron, which artifts diffinguish by particular names; but all of them may be reduced under one or other of the three following states: Wrought iron (or simply iron), Reel, and cast or raw iron.

WROUGHT IRON is the substance which we have been hitherto descibing. As it has never yet been decompounded, we confider it when pure as a fimple body; but it has feldom or never been found without some fmall mixture of foreign fubstances. These substances are either some of the other metals, or oxygen, carbon, or phosphorus.

STEEL is distinguished from iron by the following

It is fo hard as to be unmalleable while cold, or at

least it acquires this property by being immerfed while ignited into a cold liquid: for this immersion, though it has no effect upon iron, adds greatly to the hardness

It is brittle, refifts the file, cuts glass, affords sparks with flint, and retains the magnetic virtue for any length

It loses this hardness by being ignited and cooled very flowly.

It melts at above 130° Wedgewood. It is malleable when red hot, but scarcely so when raised to a white heat.

It may be hammered out into much thinner plates than iron. It is more fonorous; and its specific gravity, when hammered, is greater than that of iron.

By being repeatedly ignited in an open veffel, and hammered. it becomes wrought iron +. + Dr Pears

CAST IRON is diftinguished by the following pro. fon on Wootz, Phil.

It is fearcely malleable at any temperature. It is generally so hard as to resist the file. It can neither be Cast iron, hardened nor foftened as fleel can by ignition and cooling. It is exceedingly brittle. It melts at 130° Wedge-* Ibid. It is more fonorous than steel *.

Cast iron is converted into wrought iron by exposing it for a confiderable time in a turnace to a heat fufficiently ftrong to melt it. During the process it is constantly ffirred by a workman, that every part of it may be equally expoted to the air. In about an hour the hottest part of the mass begins to heave and swell, and to emit a lambent blue flame. This continues nearly an hour; and by that time the conversion is completed. The heaving is evidently produced by the emission of an elastic sluid !

Wrought iron may be converted into fteel by being Phil. Trans. kept for some hours in a strong red heat, surrounded 1791. with charcoal powder in a covered crucible. By this process, which is called cementation, the iron gains some

These different kinds of iron have been long known, Cause of and the converting of them into each other has been the vapractifed in very remote ages. Many attempts have ricties. been made to explain the manner in which this converfion is accomplished. According to Pliny, steel owes its peculiar properties chiefly to the water into which it is plunged in order to be cooled f. Beccher supposed & Pliny, that fire was the only agent; that it entered into the l. xxxiv. 14. iron, and converted it into steel. Reaumur was the first who attended accurately to the process; and his numerous experiments have certainly contributed to elucidate the subject. He supposed that iron was converted into steel by combining with saline and oily or sulphureous particles, and that these were introduced by the But it was the analysis of Bergman, published in 1781, that first paved the way to the explanation of the nature of these different species of iron.

By diffolving in diluted fulphuric acid 100 parts of cast iron, he obtained 40 ounce measures of hydrogen; from 100 parts of steel he obtained 48 ounce measures; and from 100 parts of wrought iron, 50 ounce measures. Now as the hydrogen is produced by the property which iron has of decomposing water and uniting with its oxygen, it is evident that the greater the quantity of hydrogen ob-

tained,

115

tained, with the more oxygen does the iron combine. But the quantities of iron were equal; they ought therefore to have combined with equal quantities of oxygen. But it is evident, from the quantities of hydrogen obtained, that the cast iron received less oxygen than either of the other two: cast iron therefore must contain already fome oxygen, fince it requires less than the other two species in order to be saturated. Here then is one difference between cast iron and the other two kinds; it contains oxygen. Steel, on the contrary, does not appear to contain any oxygen. The difference between the quantity of hydrogen produced during its folution and that of wrought iron, which contains no oxygen, is exceedingly small, and it has been found to diminish in proportion to the purity of the steel.

From 100 parts of cast iron Bergman obtained 2,2 of plumbago, or 15; from 100 parts of steel, 0,5, or # and from 100 parts of wrought iron, 0,12, or Now plumbago is composed of oths of carbon; cast iron therefore contains a considerable quantity of carbon, steel a smaller quantity, and wrought iron a very minute portion, which diminishes according to its purity, and would vanish altogether if iron could be obtained perfectly pure. Mr Grignon, in his notes on this analysis, endeavoured to prove, that plumbago was not effentially a part of cast iron and steel, but that it was merely accidentally present. But Bergman, after considering his objections, wrote to Morveau on the 18th November 1783. "I will acknowledge my mistake whenever Mr Grignon sends me a single bit of cast iron or steel which does not contain plumbago; and I beg of you, my dear friend, to endeavour to discover some such, and to fend them to me; for if I am wrong, I wish to be unde-Morveau, ceived as soon as possible *." This was almost the last yel. Me- action of the illustrious Bergman. He died a few months after at the age of 49, leaving behind him a most brilliant reputation, which no man ever more defervedly acquired. His industry, his indefatigable, his astonishing industry, would alone have contributed much to eftablish his name; his extensive knowledge would alone have attracted the attention of philosophers; his ingenuity, penetration, and accurate judgment, would alone have secured the applause; and his candour and love of truth procured him the confidence and the esteem of the world - But all these qualities were united in Bergman, and conspired to form one of the greatest men and noblest characters that ever adorned human nature.

The experiments of Bergman were fully confirmed by those of Morveau, Vandermonde, Monge, and Berthollet, who have likewise thrown a great deal of additional light on the subject. From all these experiments the following deductions may be made.

Wrought iron is a simple substance, and if perfectly

pure would contain nothing but iron.

Steel is iron combined with carbon. The proportion of this last ingredient has not yet been ascertained; Dr Pearson fixes it at 300th part at a medium. Steel, in consequence of its composition, has been called by some chemilts carburet of iron; but before affigning it that name, which has been also given to plumbago, it ought to be determined what are the proportions of carbon and iron which faturate each other. Is it the propor-

Suppl. Vol. I. Part I.

tion in which these two substances exist in steel, or that which forms plumbago? In the first case, plumbago is carburet of iron combined with carbon; in the fecond, steel is carburet combined with iron. Or is it some in. termediate proportion? Till these points be determined, perhaps it would be better to continue the old names than to risk the imposing of false ones.

Cast iron is iron contaminated with various foreign fubstances, the proportions of which vary according to circumstances. These substances are chiefly oxyd of

iron and carbon, and fometimes silica (1).

Bergman found a quantity of manyanese in the iron and steel which he examined; but it appears from the experiments of Vauquelin, that his method of determining the presence of that metal was not accurate.

Mr Vauquelin * has lately analysed four kinds of steel * Jour. de with great care, and contrived his processes with much Mines. See Nicholfon's fournal, i. ingenuity. The result of his analysis is as follows:

Carbon, 0,00789 Silica, 0,00315 Vauque-First steel, composed of Phosphorus, 0,00345 lin's analy-0,98551 fis of steel. Iron

Carbon, 0,00683 Silica, Second steel, composed of Phosphorus 0,00827 0,98217 Iron, Carbon, 0,00789 Silica, 0,00315 Third steel, composed of Phosphorus, 0,00791 Iron, 0,98105

Carbon, 0,00631 Silica, 0,00252 Fourth steel, composed of Phofphorus, 0,01520 0,97597

It cannot be concluded from these experiments, that all steel contains phosphorus and silica; far less that these substances enter necessarily into the composition of steel. This may be the case, and former analyses may not have been nice enough to detect it; but before it can be admitted, it must be shewn that these substances are always present in steel, and that it loses its essential properties when deprived of them.

Iron combines with most metals.

1. The alloy of gold and iron is very hard, and might, acording to Dr Lewis who examined it, be employed Alloys of with advantage in forming cutting instruments.

2. That iron combines with filver is certain, but hardly any thing is known about the nature of the compound.

3. Platinum is usually found alloyed with iron. Dr Lewis did not succeed in his attempts to unite these Gg

* Schrick

119

Tin.

metals by fusion, but he melted together cast iron and platinum. The alloy was excessively hard, and possessed

4. There is very little affinity between iron and mercury; they cannot therefore be amalgamated by fimple mixture, even with the affiftance of heat. Vogel affirms that he has produced an amalgam of iron by the following process: Pound one part of iron filings and two parts of alum in a mortar to a fine powder; then pour in two or three parts of mercury, and triturate till the fubstances be thoroughly mixed. Pour on a little water, and continue the trituration for about an hour. If then no particles of iron can be distinguished, pour on a little more water to wash out the alum, and then dry the amalgam. If particles of iron be perceptible, the trituration must be continued till they disappear *.

* Ann. de Chim. vi. 39.

Itsaffinities.

5. Iron may be united to copper by fusion, but not without confiderable difficulty. The alloy has been applied to no use.

The affinities of iron, according to Bergman, are as follows:

> Nickel, Cobalt, Manganese, Arfenic. Copper, Gold, Silver, Tin, Antimony, Platinum, Bismuth, Lead, Mercury, Sulphuret of alkali, Carbon? Phosphorus? Sulphur?

SECT. VII. Of Tin.

THE Phenicians were the first of those nations which make a figure in ancient history that were acquainted # Pliny, 1. with tin. They procured it from Spain* and from Britain, with which nations they carried on a very lucraand 1. 34. c. tive commerce. At how early a period they imported this metal we may eafily conceive, if we recollect that † Numbers it was in common use in the time of Moses +.

Tin is of a greyish white colour: it has a strong disagreeable taste, and emits a peculiar smell when rub-

It is very malleable: tin leaf, or tinfoil as it is called, is about 1000th part of an inch thick, and it might be beat out into leaves as thin again if fuch were wanted for the purposes of art. Its ductility, however, is exceedingly imperfect; for a tin wire toth of an inch in diameter, is capable of supporting only 49 pounds with-* Macquer's out breaking t. It is very flexible, and produces a crack-

Dictionary. ling noise when bended. + Kirwan's

Its hardness is 6+. Its specific gravity is 7,291;

Miner. ii. after hammering, 7,299 ||. 195. || Brisson. |* Pajot.

It melts at the temperature 410°, according to Dr Lewis; according to the Dijon academicians, at 419°. When heated red hot in close vessels it sublimes. It crystallizes in the form of a rhomboidal prism *.

Tin unites very readily with oxygen. When heated in contact with air, its furface foon becomes covered with a grey pellicle; when this is taken off, another appears foon after; and in this manner the whole metal may be converted into a dirty grey powder, which is the grey oxyd of tin. It is composed, according to Foureroy, of 90 parts of tin and 10 of oxygen.

When tin is heated sed hot in contact with air, it takes fire +, and burns with a very lively white flame, and + Geoffron is gradually sublimed. If the sublimate be examined, it is found to confift of a white powder; it is the white oxyd of tin. The white oxyd is perhaps never obtained quite pure by this process; it seems always to contain a mixture of grey oxyd: but it may be obtained pure by pouring nitric acid upon tin, and then drying it. That metal having a much stronger attraction for oxygen than azot has, decomposes the acid with the greatest rapidity, and assumes the appearance of a white powder, which is the white oxyd. This oxyd possesses many of the properties of an acid, and is therefore often called flannic acid. It feems to confift of about 77 parts of tin and 23 of oxygen t. t Kirwa

The affinities of the grey oxyd of tin, according to Miner. is

Bergman, are as follows:

Pyromucous acid *, Sebacic acid, Tartaric, Muriatic, Sulphuric, Oxalic, Arfenic, Phosphoric, Nitric, Succinic, Fluoric, Saccholactic, Citric, Formic, Lactic, Acetous, Boracic, Pruffic.

Tin combines readily with fulphur. This fulphuret Sulphuret may be formed by fufing the two ingredients together. It is brittle, heavier than tin, and not fo fufible. It is of a bluish colour and lamellated structure, and is capable of crystallizing. According to Bergman, it is composed of 80 parts of tin and 20 of fulphur; according to Pelletier, of 85 parts of tin and 15 of sulphur * . * Ann. de

Sulphur likewise combines with the white oxyd of Chim. xiii. tin, by mixing them together, and applying a gentle 287. heat +. This compound has been called aurum musivum. + Pelletin. It is a mass consisting of beautiful gold coloured flakes, Ibid. p. 29 and is used as a paint. It is composed of about 40 parts of fulphur and 60 of white oxyd of tin t. The process tild 293 for making this substance was formerly very complicated. Pelletier first demonstrated its real composition, and was hence enabled to make many important improvemements in the manner of manufacturing it ||.

Phosphorus is easily combined with tin, by melting in Ann. de a crucible equal parts of filings of tin and phosphoric Chim. xiii. glass. Tin has a greater affinity for oxygen than phos-280. phorus has. Part of the metal therefore combines with Phosphus

the ret,

XXXI. 22. 113 Properties of tin:

Jour. de

the oxygen of the glass during the fusion, and slies off in the state of an oxyd, and the rest of the tin combines with the phosphorus. The phosphuret of tin may be cut with a knife; it extends under the hammer, but feparates in laminæ. When newly cut it has the colour of filver; its filings refemble those of lead. When these filings are thrown on burning coals, the phosphorus takes fire. This phosphuret may likewise be formed by dropping phosphorus gradually into melted tin. According to Pelletier, to whose experiments we are indebted for the knowledge of all the phosphurets, it is composed of about 85 parts of tin and 15 of phosphorus*. Margrat also formed this phosphuret, but he Ann. de was ignorant of its composition. im. X:11.

Tin does not feem capable of combining with carbon. It is capable of combining with most of the me-

122

Alloys,

1. It mixes readily with gold by fusion; but the proportions in which these metals combine chemically are still unknown. When one part of tin and twelve of gold are melted together, the alloy is brittle, hard, and bad coloured. Twenty four parts of gold and one of tin produce a pale coloured alloy, harder than gold, but possessed of considerable ductility. Gold alloyed with no more than 1/37th of tin is scarcely altered in its Alchorne, properties, according to Mr Alchorne+; but Mr Tillet, bil. Trans. who has lately examined this alloy, found, that when-

ever it was heated it broke into a number of pieces. 2. The alloy of filver and tin is hardly known. According to Gellert and succeeding chemists, it is exceed-

ingly brittle.

3. The alloy of platinum and tin is very fufible and brittle, at least when these metals are mixed in equal

Dr Lewis. proportions ..

* See

4. Mercury diffolves tin very readily, by being poured on it when melted. This amalgam crystallizes in the form of cubes, according to Daubenton; but, according to Sage, in grey brilliant square plates, thin towards the edges, and attached to each other fo that the cavities between them are polygonal. It is composed of three parts of mercury and one of tin. The amalgam of tin is used to filver the backs of glass mirrors.

5. Tin unites very readily with copper, and forms alloys known by the names of bronze and bell-metal. 'The proportions of the ingredients cannot easily be assigned, perhaps because the alloy has an affinity both for copper and tin. The specific gravity of the alloy in all proportions is greater than the mean specific gravity of the two metals separately. When the quantity of tin is small compared to that of the copper, Toth for instance, the alloy is called bronze: it is brittle, yellow, and much heavier than copper; much more fufible, and less liable to be altered by exposure to the air. It was this alloy which the ancients used for sharp edged instruments before the method of working iron was brought to perfection. The xaxxos of the Greeks, and perhaps the es of the Romans, was nothing else. Even their copper coins contain a mixture of tin *.

Dizé's A-6. Tin seems capable of being united to iron by funalysis, fion. That there is an affinity between these metals is Phys. 1790. evident from their adhesion when iron is dipt into melted tin. This is the method of making tinplate.

The affinities of tin, according to Bergman, are as ties of tin. follows:

Zine. Mercury, Copper, Antimony. Gold, Silver, Lead, Manganele, Nickel, Arfenic, Platinum, Bismuth, Cobalt, Sulphuret of alkali, Oxygen? Sulphur? Phosphorus?

SECT. VIII. Of Lead.

LEAD appears to have been very early known. It is mentioned feveral times by Moses. The ancients feem to have confidered it as nearly related to tin.

Lead is of a bluish white colour, somewhat darker Properties than tin. When newly melted it is very bright, but of lead. foon becomes tarnished by exposure to the air. It has scarcely any taste, but emits on friction a peculiar smell.

It is very malleable, and may be reduced to thin plates by the hammer; but its ductility is very im-

perfect: a wire of lead to the of an inch in diameter is only capable of supporting a weight of 20½ pounds*.

Its hardness is 5; its specific gravity is 11,3523‡. + Kirwan's Its specific gravity is not increased by hammering, nei. Miner. ii. ther does it become harder, as is the case with other me- 202. tals: a proof that the hardness which metals assume un- \$ Brisson. der the hammer is in consequence of an increase of density.

It melts, according to Dr Lewis, at 540° Fahrenheit; according to the Dijon academicians, at 549°. When exposed to a violent heat it evaporates completely.

When cooled flowly, after being fused, it crystallizes .. The Abbé Mongez obtained it in quadrangular pyramids, lying on one of their fides. Each pyramid was composed as it were of three layers. Pajot obtained it in the form of a polyhedron with 32 fides, formed by the concourse of six quadrangular pyramids +.

Lead stains paper or the fingers of a bluish black co. Phys. xxxviii. 53.

There is a strong affinity between this metal and oxy- Its oxyds. gen. When nitric acid is poured upon it, an effervescence enfues, owing to the decomposition of the acid; the lead feizes oxygen from it, and is converted into a white powder, which may be obtained pure by evaporating it to dryness, and then washing it in pure water. This is the white onyd of lead. It is composed of about 95 parts of lead and five of oxygen t. The affinities t Kirwan's of this oxyd are, according to Bergman, as follows:

Sulphuric acid, Sebacic, Saccholactic, Oxalic, Arfenic, Tartarous, Phosphoric, Muriatic, Gg 2

Benzoic,

§ Fources

Benzoic (v)? Sulphurous, Suberic? \ (v) Nitric, Pyromuçous (v)? Fluoric, Citric, Formic, Lactic. Acetous. Boracic, Pruffic, Carbonic, Fixed alkali.

When lead is exposed to heat in contact with air, its furface is foon covered with a grey pellicle; when this is taken off, another foon forms: and in this manner the whole lead may foon be converted into a dirty grey powder, which feems to be the white oxyd mixed with a little lead. When this powder is heated red hot, it affumes a deep yellow colour. This is the yellow oxyd of lead, formerly called massicot. If the heat be continued, the colour is gradually changed to a beautiful red. This is the red oxyd of lead, formerly called minium. It is composed, as Lavoisier has shewn, of 88 parts of lead

and 12 of oxygen *.

Par. 1781. The manner in which these changes are brought about is evident; the metal gradually absorbs oxygen from the atmosphere. This has been actually proved by experiment. These oxyds (if they really differ in the proportion of oxygen) refemble acids in several of their properties. They are very eafily converted into glass by fusion. Scheele has shewn that there is also a brown oxyd of lead, which contains more oxygen than

any of the others. Sulphuret,

Sulphur unites eafily to lead by fusion. The fulphuret of lead is brittle, of a deep grey colour, and much less susible than lead. These two substances are often found naturally combined; the compound is then called galena. Sulphuret of lead is composed, according to the experiments of Wenzel, of 868 parts of lead and 132 of

+ Kirwan's fulphur +. Miner. ii.

Phosphu-

Chim. xiii.

Phosphuret of lead may be formed by mixing together equal parts of filings of lead and phosphoric glass, and fusing them in a crucible. It may be cut with a knife, but separates into plates when hammered. It is of a filver white colour with a fhade of blue, but it foon tarnishes when exposed to the air. This phosphuret may also be formed by dropping phosphorus into melted lead. It is composed of about 12 parts of phof-

phorus and 88 of lead 1. \$ Pelletier, Ann de

Lead combines with most of the other metals. 1. Little is known concerning the alloy of lead and gold. It is faid to be brittle.

114. Alloys, and

2. The alloy of filver and lead is very fufible, and neither elastic nor sonorous.

3. Platinum and lead unite in a ftrong heat: the alloy is brittle, of a purplish colour, and soon changes on

exposure to the air f. 4. Mercury, when poured upon melted lead, diffolves it readily. The amalgam is white and brilliant, and assumes a solid form. It is capable of crystallizing. The crystals are composed of one part of lead and one and a half of mercury ||.

5. Copper and lead combine easily by fusion; but the cademician

alloy has not been applied to any use. 6. Iron does not unite with lead.

7. Lead and tin may be combined by fusion. The alloy in the proportion of two parts of lead and one of tin is more foluble than either of the metals feparately. It is accordingly used by plumbers as a solder.

Lead, when taken internally, acts as a poison. Its Affinities

affinities, according to Bergman, are as follows:

Gold, Silver, Copper, Mercury, Bilmuth, Tin, Antimony, Platinum, Arlenic, Sulphuret of alkali, Sulphur, Phofphorus?

The ancients gave to the feven metals last described Names an (omitting platinum, which they did not know) the names marks of the planets, and denoted each of them by particular given to marks, which represented both the planet and the metal. by the an-

Gold was the Sun, and represented by O. Silver the Moon, Mercury Mercury, Copper Venus, Iron Mars, ₫. Tin Jupiter, 4. ъ. Saturn,

It feems most probable that these names were first given to the planets; and that the feven metals, the only ones then known, were supposed to have some relation to the planets or to the gods that inhabited them, as the number of both happened to be the same. It appears from a passage in Origen, that these names first arose among the Persians (w). Why each particular metal was denominated by a particular planet it is not easy to see. Many conjectures have been made, but scarcely any of them are satisfactory.

As

(v) Benzoat of lead is decomposed by muriatic acid. Trommsdorf, Ann. de Chim. xi. 317.

(v) Suberic acid decomposes nitrat of lead. See Jameson's Mineralogy, p. 166. Zoonic acid produces the same effect, as Berthollet has observed.

(v) Schrickel places it after the three mineral acids.

(w) Contra Celfum, lib. vi. 22.-" Celfus de quibusdam Persarum mysteriis sermonem facit. Harum rerum, inquit, aliquod reperitur in Persarum doctrina Mithracisque corum mysteriis vestigium. In illis enim duæ cælestes conversiones, alia stellarum fixarum, errantium alia, et animæ per eas transitus quodam symbolo repræsentantur, quod hujusmodi est. Scala altas portas habens, in summa autem octava porta. Prima portarum plumbea, altera stannea,

Zinc.

As to the characters by which these metals were expressed, astrologers seem to have considered them as the f attributes of the deities of the same name. The circle irks, in the earliest periods among the Egyptians was the ng fymbol of divinity and perfection; and feems with great propriety to have been chosen by them as the character of the sun, especially as, when surrounded by small strokes projecting from its circumference, it may form fome representation of the emission of rays. The semicircle is, in like manner, the image of the moon; the only one of the heavenly bodies that appears under that form to the naked eye. The character h is supposed to represent the scythe of Saturn; 4 the thunderbolts of Jupiter; of the lance of Mars, together with his shield; 2 the looking glass of Venus; and & the caduceus or wand of

The alchemists, however, give a very different account of these symbols. Gold was the most perfect metal, and was therefore denoted by a circle. Silver approached nearest it; but as it was inferior, it was denoted only by a semicircle. In the character & the adepts discovered gold with a filver colour. The cross at the bottom expressed the presence of a mysterious something, without which mercury would be filver or gold. This fomething is combined also with copper; the posfible change of which into gold is expressed by the character Q. The character of declares the like honourable affinity also; though the semicircle is applied in a more concealed manner: for, according to the properest mode of writing, the point is wanting at the top, or the upright line ought only to touch the horizontal, and not to interfect it. Philosophical gold is concealed in fleel; and on this account it produces fuch valuable medicines. Of tin, one half is filver, and the other confifts of the unknown fomething; for this reason the cross with the half moon appears in 4. In lead this fomething is predominant, and a fimilitude is observed in it to filver. Hence in its character h the cross stands at the top, and the filver character is only suspended on the right hand behind it.

The fact, however, according to Professor Beckmann, from whom most of the above remarks have been taken, feems to be, that these characters are mere abbreviations of the old names of the planets. "The character of ory of Mars (he observes *), according to the oldest mode of Ooupos, under which the Greek mathematicians under-

stood that deity; or, in other words, the first letter . with the last letter ; placed above it. The character of Jupiter was originally the initial letter of Zeve; and in the oldest manuscripts of the mathematical and astrological works of Julius Firmicus, the capital Z only is used, to which the last letter i was afterwards added at the bottom, to render the abbreviation more distinct. The supposed looking-glass of Venus is nothing else than the initial letter distorted a little of the word Dwogopos, which was the name of that goddess. The imaginary scythe of Saturn has been gradually formed from the two first letters of his name Kpovos, which transcribers, for the fake of dispatch, made always more convenient for use, but at the same time less perceptible. To discover in the pretended caduceus of Mercury the initial letter of his Greek name Existar, one needs only look at the abbreviations in the oldest manuscripts, where they will find that the was once written as C; they will remark also that transcribers, to distinguish this abbreviation from the rest still more, placed the C thus O, and added under it the next letter r. If those to whom this deduction appears improbable will only take the trouble to look at other Greek abbreviations, they will find many that differ still farther from the original letters they express than the present character & from the C and r united. It is possible also that later transcribers, to whom the origin of this abbreviation was not known, may have endeavoured to give it a greater resemblance to the caduceus of Mercury. In short, it cannot be denied that many other astronomical characters are real fymbols, or a kind of proper hieroglyphics, that reprefent certain attributes or circumstances, like the characters of Aries, Leo, and others quoted by Saumaise."

SECT. IX. Of Zinc.

THE ancients were acquainted with a mineral to which they gave the name of Cadmea, from Cadmus, who first melted with copper it formed brass; and that when 134 burnt, a white fpongy kind of ashes was volatilised, which of zinc. they used in medicine*. This mineral contained a good * Pliny, I. deal of zinc; and yet there is no proof remaining that 34. c. 2. and the ancients were acquainted with that metal (x). It 10. is first mentioned in the writings of Albertus Magnus, who died in 1280; but whether he had seen it is not so clear, as he gives it the name of marcasite of gold, which implies, one would think, that it had a yellow colour (v).

flannea, tertia ex ære, quarta ferrea, quinta ex ære mixto, fexta argentea, septima ex auro. Κλιμαξ ύψιπυλος, επε δαιτη πυλη ογδοη. 'Η πρωτη των πυλαν μολίζδου, ή δευτερα κασσιτεριυ, ή τειτη χαλκευ, ή τεταρτη σιδτρου, ή πεμπτη καρασου νουιτματος, ή έκτη αργυρου, χρυσου δ' ή έξδομη. Primiim assignant Saturno tarditatem illius sideris plumbo indicantes: alteram Veneri, quam referunt, ut ipsi quidem putant, stanni splendor et mollities; tertiam Jovi, aheneam illam quidem et solidam : quartam Mercurio, quia Mercurius et ferrum, uterque operum omnium tolerantes, ad mercaturam utiles, laborum patientissimi. Maiti quintam, inæqualem illam et variam propter mixturam. Sextam, quæ argentea est, lunæ; septimam auream soli tribuunt, quia solis et lunæ colores hæc duo metalla referunt."

Borrichius suspects, with a good deal of probability, that the names of the gods in this passage have been transposed by transcribers, either through ignorance or design. He arranges them as follows: "Secundam portam faciunt Jovis, comparantes ei stanni splendorem et mollitiem; tertiam Veneris æratam et solidam; quartam Martis, est enim laborum patiens, æque ac ferrum, celebratus hominibus; quintam Mercurii propter misturam inæqualem ac variam, et quia negotiator est; sextam Lunæ argenteam; septimam Solis auream." Ol. Borrichius de

ortu et progressu chemie. Hafniæ, 1668, 4to, p. 29.

(x) Grignon indeed fays, that fomething like it was discovered in the ruins of an ancient Roman city in Champagne; but the substance which he took for it was not examined with any accuracy. It is impossible therefore to draw any inference whatever from his affertion. Bulletin des fouilles d'une ville Romaine. p. 11.

(x) The passages in which he mentions it are as follows: - De Mineral. lib. ii. cap. 11. "Marchasta, sive marchafida 4to.

. 2

* So

+ See Vol. 6. of bis

The word zine occurs first in the writings of Paracelsus, who died in 1541. He informs us very gravely, that it is a metal, and not a metal, and that it confifts chiefly of the ashes of copper +. This metal has also

been called spelter. Works in

Zinc has never been found in Europe in a state of purity, and it was long before a method was discovered of extracting it from its ore (z). Henkel pointed out one in 1721, and Von Swab obtained it by distillation in 1742, and Margraf published a process in the Der-\$ Bergman, lin Memoirs in 1746\$.

ii 30%. 135 Properties

& Sage.

It is of a bluish white colour, somewhat lighter than lead. It has neither tafte nor smell.

It has some degree of malleability; for by compresfion it may be reduced into thin plates §; but it cannot be drawn out into wire. It is more brittle when hot than when cold.

+ Briffon. 1 Kirwan,

* Kirwan's Its hardness is 6 *. Its specific gravity, when com-Miner. ii. pressed, is 7,1908 +; in its usual state, 6,862 1. It melts at about 699° Fahrenheit f.

When allowed to cool flowly, it cryftallizes in small bundles of quadrangular prisms, disposed in all direc-§ Bergman. tions. If they are exposed to the air while hot, they * Mongez. affume a blue changeable colour *.

When zinc is kept melted in contact with air, it Its oxyds, becomes covered with a grey pellicle, which gradually assumes a yellowish tint. By removing this pellicle from time to time, the whole of the metal may be reduced into a grey powder. This is the grey oxyd of zinc. This oxyd is probably composed of about 85 parts of † Morveau, zinc and 15 of oxygen †. When zinc is violently heated, it burns with a bright white flame, and at the fame time a quantity of very light white flakes are fublimed. These flakes are the white oxyd of zinc, which contains a good deal more oxygen than the grey oxyd(A).

Zinc may also be oxydated by folution in acids. particularly the nitric acid. Whether the oxyd obtained by precipitating zinc from its folution in that acid, or by distilling that acid off zinc, be really different from the white oxyd, has not yet been properly afcertained; but one would be apt to suspect, from the experiments mentioned by Mr Kirwan, that it contained a good deal more oxygen H.

The affinities of the oxyds, or rather of the white ii. 49 oxyd of zinc, are, according to Bergman, as follows:

Oxalic acid, Sulphuric, Pyromucous *, Muriatic, Saccholactic, Nitric, Sebacic. Tartaric, Phosphoric, Citric, Succinic, Fluoric, Arfenic, Formic, The state of the state of Lactic, Acetous, Boracic, Boracic - Pruffic. Carbonic, . Ammonia.

There is an affinity between fulphur and zinc, as is sulphur evident from these two substances being often found united; but it is very difficult to form the fulphuret of zine artificially, on account of the rapid oxydation and confequent volatilization of the zinc. Morveau, however, succeeded in forming it.

Zinc may be combined with phosphorus, by dropping Pho fmall bits of phosphorus into it while in a ftate of fu-rets, fion. Pelletier, to whom we are indebted for the experiment, added also a little refin, to prevent the oxydation of the zinc. Phosphuret of zinc is of a white colour, a metallic splendor, but resembles lead more than zinc. It is fomewhat malleable. When hammered or filed, it emits the odour of phosphorus. When expofed to a strong heat, it burns like zinc *.

Phosphorus Chin

marchasida ut quidam dicunt, est lapis in substantia, et habet multas species, quare colorem accipit cujuslibet metalli, et sic dicitur marchasita argentea et aurea, et sic dicitur aliis. Metallum tamen quod colorat eum non distillat ab ipfo, sed evaporat in ignem, et sic relinquitur cinis inutilis, et hic lapis notus est apud alchimicos, et in multis locis veniuntur.

Lib. iii. cap. 10. "Æs autem invenitur in venis lapidis, et quod est apud locum qui dicitur Goselaria est purisfimum et optimum, et toti substantiæ lapidis incorporatum, ita quod totus lapis est sicut marchasita aurea, et profundatum est melius ex eo quod purius.

Lib. v. cap. 5. "Dicimus igitur quod marchafita duplicem habet in fui creatione fubliantiam, argenti vivi scilicet mortificati, et ad fixionem approximantis, et fulphuris adurentis. Ipfam habere sulphureitatem comperimus manifesta experientia. Nam cum sublimatur, ex illa emanat substantia sulphurea manifesta comburens. Et sine sublimatione similiter perpenditur illius sulphureitas.

"Nam si ponatur ad ignitionem, non suscipit illam priusquam inflammatione sulphuris inflammetur, et ardeat. Ipfam vero argenti vivi substantiam manifestatur habere sensibiliter. Nam albedinem præstat Veneri meri argenti, quemadmodum et ipsum argentum vivum, et colorem in ipsius sublimatione cælestium præstare, et luciditatem manisestam metallicam habere videmus, quæ certum reddunt artificem Alchimiæ, illam has substantias continere in

(z) The real discoverer of this method appears to have been Dr Isaac Lawson. See Pott, III. diss. 7. and Watfon's Chemical Effays.

(A) Pott observed, that it was roth heavier than the zinc from which it was obtained; and Mr Boyle had long before afcertained the same fact .- Shaw's Boyle, II. 391, 394.

This oxyd of zinc was well known to the ancients. Diofcorides describes the method of preparing it. The ancients called it pompholy , the early chemists gave it the name of lana philosophica. Dioscorides compares it to wool, εριων τολυπαις αφομοιονίαι, ν. 55. p. 352.

Miner. ii. 489.

* Ann. de

And affinis

Pholphorus combines also with the oxyd of zinc, a compound which Margraf had obtained during his experiments on phosphorus. When 12 parts of oxyd of zinc, 12 parts of phosphoric glass, and two parts of charcoal powder, are distilled in an earthen ware retort, and a strong heat applied, a metallic substance sublimes of a filver-white colour, which when broken has a vitreous appearance. This, according to Pelletier, is phosphuret of oxyd of zinc. When heated by the blowpipe, the phosphorus burns, and leaves behind a glass ", transparent while in fusion, but opaque after cooling +.

Zinc also combines with carbon, and forms carburet r et, of zinc. The French chemists have shewn that zinc ge-

nerally contains some carbon.

Zinc combines with most of the metals:

1. It mixes with gold in any proportion. A /8, alloy is the whiter and the more brittle the greater quantity of zinc it contains. An alloy, confifting of equal parts of these metals, is very hard and white, receives a fine polish, and does not tarnish readily. It has ". A. therefore been proposed by Mr Malouin t as very proper for the specula of telescopes. One part of zinc is taid to destroy the ductilility of 100 parts of gold ||.

2. The alloy of filver and zinc is eafily produced by

er's 2. The alloy of file ary. fusion. It is brittle.

3. Platinum combines very readily with zinc. 'I'he alloy is brittle, pretty hard, very fufible, of a bluish ewis. white colour, not so clear as that of zinc *.

4. Zinc may be combined with mercury by fusion. The amalgam is folid. It crystallizes when melted and cooled flowly into lamellated hexagonal figures, with cavities between them. They are composed of one part Di- rub on electrical machines, in order to excite electri-

5. Zinc combines very readily with copper. This alloy, which is called brass, was known to the ancients. They used an ore of zinc to form it, which they called cadmia. This alloy was very much valued by the ancients. Dr Watson has proved that it was to brass unche- which they gave the name of orichalcum*. Their as was copper or rather bronze (B). Brass is composed of about three parts of copper and one of zinc. It is of a beautiful yellow colour, more fufible than copper, and not so apt to tarnish. It is malleable, and so ductile that it may be drawn out into wire. When the alloy contains three parts of zinc and four of copper, it affumes a colour nearly the fame with gold, but it is not so malleable as brass. It is then called pinchbeck, prince's metal, or Prince Rupert's metal.

6. The alloy of iron and zinc has scarcely been examined: but Malouin has shewn that zinc may be used

inflead of tin to cover iron plates; a proof that there is Antimony.

an affinity between the two metals ‡.

7. Tin and zinc combine eafily. The alloy is harder par. 1742. than tin. This alloy is often the principal ingredient in

the compound called pewter.

8. Mr Gmelin has succeeded in forming an alloy of zinc and lead by fusion. He put some suet into the mixture, and covered the crucible, in order to prevent the evaporation of the zinc. When the zinc exceeded the lead very much, the alloy was malleable, and much harder than lead. A mixture of two parts of zinc and one of lead formed an alloy more ductile and harder than the last. A mixture of equal parts of zinc and lead formed an alloy differing little in ductility and colour from lead; but it was harder, and more susceptible of polish, and much more fonorous. When the mixture contained a smaller quantity of zinc, it still approached nearer the ductility and colour of lead, but it continued harder, more sonorous, and susceptible of polish, till the proportions approached to one of zinc and 16 of lead, when the alloy differed from the last metal only in being somewhat harder*.

The affinities of zinc, according to Bergman, are as Chim. ix.

follows:

Copper, Antimony, Tin, Mercury, Silver, Gold, Cobalt. Arlenic, Platinum, Bismuth, Lead, Nickel, Iron.

SECT. X. Of Antimony.

THE ancients were acquainted with an oxyd of antimony to which they gave the names of olimu, and flibium. Pliny * informs us, that it was found in filver ore; and * Pliny, I. we know that at prefent there are filver ores † in which xxxiii. c. 6. it is contained. It was used as an external application **Miner.* ii. to fore eyes; and Pliny gives us the method of preparing 110 it t. Galen supposes that the researces of Hippocrates + Pliny, ibid; was a preparation of antimony; but this wants proof. It does not appear, however, that the ancients confider. Difcovery ed this substance as a metal, or that they knew antimo- of antimo-ny in a state of purity (c). Who first extracted it from its ore we do not know; but Basil Valentine, a chemist of the 16th century, is the first who describes the

(B) The ancients do not feem to have known accurately the difference between copper, brass, and bronze. Hence the confusion observable in their names. They considered brass as only a more valuable kind of copper, and therefore often used the word as indifferently to denote either. It was not till a late period that mineralogists began to make the distinction. They called copper as cyprium, and afterwards only cyprium, which in process of time was converted into cuprum. When these changes took place is not known accurately. Pliny uses cyprium, lib xxxvi. c. 26. The word cuprum occurs first in Spartian, who lived about the year 290. He says in his life of Caracalla, cancelli ex are vel cupro.

(c) Mr Roux indeed, who at the request of Count Caylus analysed an ancient mirror, found it composed of copper, lead, and antimony. This would go far to convince us that the ancients knew this metal, provided it could be proved that the mirror was really an ancient one; but this point appears to be extremely doubtful.

. 489.

+ Ibid.

& Schrickel.

Antimony, process. To him indeed we are indebted for our acquaintance with many of the properties of this metal.

Antimony is of a white colour, with a shade of grey.

Fourcroy. It has a fenfible tafte, but no fmell ||.

It is neither malleable nor ductile, but exceedingly Properties of antimo- brittle. Its specific gravity, according to Brisson, is 6,702; according to Bergman, 6,860. Its hardness is § Kirwan's 6,5 §. It melts at 809° Fahrenheit ¶. If after this the Miner. ii. heat be increased, the metal evaporates. On cooling it Bergman. assumes the form of oblong crystals, perpendicular to the internal furface of the vessel in which it cools. It is to this crystallization that the laminated structure

which antimony always affumes is owing.

Neither air nor water have much effect on this metal. 144 When antimony is beat to powder, and exposed for Its oxyds, some time to a gentle heat, it absorbs oxygen, and is converted into a grey powder. This is the grey oxyd of antimony. When this metal is kept for some time melted in contact with air, it sublimes in the form of a white powder, formerly called fnow or white flowers of anti-. mony. This is the white oxyd of antimony. This oxyd may be procured also by pouring nitric acid on antimony, and then evaporating to dryness. Antimony attracts the oxygen from the acid, and thus paffes very rapidly into the flate of an oxyd. This oxyd feems to confift of about 77 parts of antimony and 23 of oxy-* Kirwan's gen *. The nature of these oxyds has never yet been Miner. ii. accurately inquired into. It is not even known at prefent whether the white oxyd obtained by heat and that obtained by nitric acid contain the fame quantity of oxygen. The experiments mentioned by Mr Kirwan make the contrary probable +; and yet these oxyds have too many qualities in common to render these experiments conclusive. The white oxyd of antimony is foluble in water ‡; and when fused, is converted into a transparent glass. The white oxyd obtained by nitric + Rouelle.

acid feems to possess many of the properties of an acid. The affinities of the grey oxyd of antimony are, ac-

cording to Bergman, as follows:

Sebacic acid, Muriatic, Benzoic (D)? Oxalic, - Sulphuric, Pyromucous §,. Nitric, Tartarous, Saccholactic, Phosphoric, Citric, Succinic, Fluoric, Arfenic,

Formic, Lactic,

Acetous, Boracic, Pruffic,

· Carbonic. Sulphur combines readily with antimony. This com-Sulphurets, pound is often found native: it was formerly called antimony, and the pure metal was then called regulus of the proportions of their ingredients.

antimony. Sulphuret of antimony is eafily melted by a Antim moderate heat: if the heat be continued, the fulphur fublimes, and at the same time the antimony absorbs oxygen, and is converted into a grey oxyd. This fulphuret is composed of 74 parts of antimony and 26 of fulphur *.

The grey oxyd of antimony is also capable of combi-iii. 16 ning with about 400 of fulphur. This compound, by fusion, may be converted into glass. It was formerly used in medicine under the name of glass of antimony.

When equal parts of antimony and phosphoric glass Phospi are mixed together with a little charcoal powder, and ret, melted in a crucible, phosphuret of antimony is produced. It is of a white colour, brittle, appears laminated when broken, and at the fracture there appear a number of small cubic facettes. When melted it emits a green flame, and then fublimes in the form of a white powder. Phosphuret of antimony may likewise be prepared by fusing equal parts of antimony and phosphoric glass, or by dropping phosphorus into melted antimony +.

Antimony is capable of combining with most of the Ann. de

metals.

1. Gold may be alloyed with antimony by fufing 132. them together. The antimony is afterwards separable by an intense heat. This alloy is little known, and has never been applied to any use.

2. The alloy of filver and antimony is brittle, and its fpecific gravity, as Gellert has observed, is greater than intermediate between the specific gravities of the two

metals which enter into it.

3. Platinum eafily combines with antimony. The alloy is brittle, and much lighter than platinum*. The Dr L antimony cannot afterwards be completely separated by

4. Mercury does not eafily combine with antimony. Mr Gellert succeeded in amalgamating this metal by putting it into hot mercury, and covering the whole with water.

5. Copper combines readily with antimony by fusion. The alloy is of a beautiful violet colour, and its speci-

fic gravity is greater than intermediate +.

6. Iron combines with antimony, and forms a brittle hard alloy, the specific gravity of which is less than intermediate. The magnetic quality of iron is much more diminished by being alloyed with antimony than with any other metal t.

7. The alloy of tin and antimony is white and brittle;

its specific gravity is less than intermediate s.

8. When equal quantities of lead and antimony are fufed, the alloy is porous and brittle: three parts of lead and one of antimony form a compact alloy, malleable, and much harder than lead: 12 parts of lead and one of antimony form an alloy very malleable, and a good deal harder than lead: 16 parts of lead and one of antimony form an alloy which does not differ from lead except in hardness ¶. This alloy forms printers types. ¶ Gmelling

9. Zinc and antimony form a brittle alloy, the speci-Ann. de fic gravity of which is less than intermediate *. The 319. alloys of antimony are little known. Gellert is almost * Gellert the only person who has examined them. It would require a great number of experiments to be able to fix

& Dr Lewis.

The affinities of antimony are, according to Bergman, as follows:

Iron, Copper, Tin, Lead, Nickel, Silver, Bismuth, Zinc, Gold, Platinnm, Mercury, Arfenic, Cobalt, Sulphuret of arfenic, Sulphur, Phoiphorus?

SECT. XI. Of Bismuth.

THE ancients appear to have known nothing of bifmuth, nor do we know who discovered it; but it is first mentioned by George Agricola, who was born about the end of the 15th century.

Bismuth is of a yellowish or reddish white colour, and

Pro perties of bismuth, almost destitute both of taste and sinell.

It is brittle. Its hardness is 6 *. Its specific gravity is 9,8227 +. It melts at 460° Fahrenheit t.

When heated in close vessels, it sublimes. When allowed to cool flowly after fusion, it crystallizes.

Bismuth is not altered by water. When exposed to

the air it foon tarnishes.

When bismuth is kept fused in contact with zir, it is gradually oxydated. When heated red hot, it emits a very faint blue flame, and its oxyd evaporates in the form of a yellowish smoke. When this smoke is collected, it is found to confift of a brown-coloured powder. This is the brown oxyd of bismuth. It is composed of * Kirwan's about 94 parts of bismuth and 6 of oxygen *. Bismuth decomposes nitric acid with great rapidity, by attracting its oxygen. If the quantity of acid be confiderable, it dissolves the oxyd as it forms; but the greater part of it may be precipitated by diluting the acid with water. This precipitate, which is a white powder, is white oxyd of bismuth. It is composed of about 84 parts bismuth and 16 of oxygen +.

The affinities of the oxyds of bifmuth are, according

to Bergman, as follows:

Oxalic acid, Arfenic, Tartarous, Phosphoric, Sulphuric, Sebacic, Muriatic, Benzoic (E)? Nitric, Fluoric, Saccholactic, Succinic, Citric.

SUPPL. VOL. I. Part I.

Formie, Lactic, Acetous, Pruffic, Carbonic, Ammonia.

Sulphur combines readily with bismuth by fusion. Sulphuret. The fulphuret of bismuth is of a bluish grey colour, and crystallizes into beautiful tetrahedral needles. It is composed of 85 parts of bismuth and 15 of sulphurt. # Wenzel,

There appears to be little affinity between bismuth and Kirwan's phosphorus. Mr Pelletier attempted to produce the phosphuret of bismuth by various methods without success. 151 When he dropped phosphorus, however, into bismuth Phosphuin fusion, he obtained a substance which did not apparet, rently differ from bismuth, but which, when exposed to the blow-pipe, gave evident figns of containing phofphorus. Phosphuret of bismuth, according to Pelletier, is composed of about 96 parts of bilmuth and four of phosphorus *. Chim. xiii.

Dismuth combines readily with most of the metals. 1. Equal parts of bismuth and gold form a brittle al-

loy, nearly of the fame colour with bifmuth +. 2. Equal parts of bismuth and filver form also a brittle Keir, alloy, but less so than the last. The specific gravity of Dia. both thele is greater than intermediate ‡.

3. The alloy of bismuth and platinum is also very brittle. When exposed to the air it assumes a purple, violet, or blue colour. The bismuth may be separated by heat J.

4. Mercury dissolves bismuth very easily. The amalgam is more fluid than pure mercury, and has the property of dissolving lead and rendering it also fluid ||. It || Gramer. is capable, however, of crystallizing. The crystals are either octahedrons, lamellated triangles, or hexagons. They are composed of one part of bismuth and two of T Clim. Di= mercury .

5. The alloy of copper and bismuth is not so red as jon, i. 3.

6. Nothing is known concerning the alloy of iron and bifmuth.

7. Bilmuth and tin unite readily. A fmall portion of bismuth increases the brightness, hardness, and sonorousness of tin: it often therefore enters into the composition of the compound called pewter. Equal parts of tin and bismuth form an alloy that melts at 2809: eight parts of tiu and one of bismuth, melt at 3900: two parts of tin and one of bismuth, at 3300+. + Dr Lewis.

8. The alloy of lead and bifinuth is of a dark grey

colour, a close grain, but very brittle.

9. Bismuth does not combine with zinc.

10. The alloy of antimony and bismuth is unknown. Bifmuth likewise enters into triple compounds with metals: Two parts of lead, three of tin, and five of bismuth, form an alloy which melts at the heat of boiling water, which is 2120.

The affinities of bilmuth, according to Bergman, are And affini-

Alloys,

Mercury, Antimony, Tin, Copper, Platinum, Nickel, Iron, Sulphuret of alkali, Sulphur, Phosphorus?

SECT. XII. Of Arfenic.

THE word arfenic (agosvixov) occurs first in the works of Dioscorides, and of some other authors who wrote about the beginning of the Christian era. It denotes in their works the same substance which Aristotle had ealled σανδαραχη (F), and his disciple Theophrastus apperizor, which is a reddish coloured mineral, composed of arfenic and fulphur, used by the ancients in painting, and as a medicine.

The white oxyd of arfenic, or what is known in commerce by the name of arfenic, is mentioned by Avicenna in the 11th century; but at what period the metal called arfenic was first extracted from that oxyd is unknown. Paracelfus feems to have known it. It is mentioned by Schroeder in his Pharmacopæia published

* Bergman, in 1649 *. ii. 278.

Nickel, Cobalt, Copper, Iron, Silver, Tin, Gold, Platinum, Zinc, Antimony, Sulphuret of alkali, Sulphur, Phosphorus.

SECT. XIII. Of Cobalt.

A MINERAL called cobalt (G), of a grey colour, and very heavy, has been used in different parts of Europe fince the 15th century to tinge glass of a blue colour. From this mineral Brandt obtained in 1733 a new me-

+ Att. Up- tal, to which he gave the name of cobalt +.

Cobalt is of a white colour, inclining to a bluish or fal. 1733. steel grey. When pure, it is somewhat malleable while Properties red hot \(\pm\). Its hardness is 8 \(\pm\). Its specific gravity is \$ Leonhardi. 8, 15 (H). It requires for fusion a heat at least as great Kirreun's as cast iron, which melts at 130° Wedgewood. No Miner ii. heat has been produced great enough to volatilize it ||.

Cobalt, when pure, does not feem to be affected by

Bergman, air or water.

It is attracted by the magnet.

It is not oxydated by heat without very great diffi- Cobalt culty; but it has the property of decomposing nitric acid, and of attracting oxygen by that means with its oxyds, great rapidity.

The oxyd of cobalt is of fo deep a blue as to appear The oxyd procured by heat is composed of 88 parts of cobalt and 12 of oxygen; that by nitric acid contains about 77 parts of cobalt and 23 of oxygen *. * Kirwan's Its affinities, according to Bergman, are as follows:

268.490.

Oxalic acid, Muriatic, Sulphuric, Tartarous, Nitric, Sebacic, Phosphoric, Fluoric, Saccholactic, Succinic, Citric, Formic, Lactic, Acetous, Arfenic, Boracic, Pruffic, Carbonic, Ammonia.

The fulphuret of cobalt is not formed without difficul-Sulphuret, It is fcarcely known.

Phosphuret of cobalt may be formed by heating the Phosphumetal red hot, and then gradually dropping in small bits ret, of phosphorus. It contains about 13th of phosphorus. It is white and brittle, and when exposed to the air foon lofes its metallic luftre. The phosphorus is separated by heat, and the cobalt is at the same time oxydated. This phosphuret is much more fusible than pure + Pelletier, cobalt +.

The combinations of cobalt with other metals have Ann. de Chim. Xiii. been very little examined into.

1. The alloy of gold and cobalt is not known. 2. Cobalt does not combine with filver by fusion ‡; Alloys,

but, according to Gellert, the alloy of filver and cobalt \$ Bergman's may be formed: it is brittle and of a grey colour f. 3. The alloy of platinum and cobalt is unknown.

& Metallur. 4. Mer-Chim. Hh2

(G) The word cobalt feems to be derived from cobalus, which was the name of a spirit that, according to th superstitious notions of the times, haunted mines, destroyed the labours of the miners, and often gave them a great deal of unneceffary trouble. The miners probably gave this name to the mineral out of joke, because it thwarted them as much as the supposed spirit, by exciting false hopes, and rendering their labour often fruitlefs; for as it was not known at first to what use the mineral could be applied, it was thrown aside as useless. It was once customary in Germany to introduce into the church-service a prayer that God would preserve miners

and their works from kobalts and spirits. See Beckmann's Hillory of Inventions, II 362. Mathefius, in his tenth fermon, where he speaks of cadmia fossilis (probably cobalt ore), says, "Ye miners call it kotolt; the Germans call the black devil and the old devil's whores and hags, old and black kobel, which

by their witchcraft do injury to people and to their cattle." Lehmann, Paw, Delaval, and feveral other philosophers, have supposed that fmalt (oxyd of cobalt melted with glass and pounded) was known to the ancients, and used to tinge the heautiful blue glass thill visible in some of their works; but we learn from Gmelin, who analysed some of these pieces of glass, that they owed their blue colour, not to the presence of cobalt but of iron.

According to Lehmann, cobalt ore was first used to tinge gla's blue ty Christopher Schurer, a glass-maker at

Platten, about the year 1540. (4) Berg. II. 231. According to Briffon, 7,8119.

Difcovery

of nickel.

Iron, Nickel, Arfenic, Copper, Gold, Platinum, Tin, Antimony, Zinc, Sulphuret of alkali,

Sulphur, Phosphorus?

SECT. XIV. Of Nickel.

A HEAVY mineral of a red colour is met with in feveral parts, of Germany, which bears a strong resemblance to an ore of copper; but none of that metal can be extracted from it: for this reason the Germans called it kupfer nickel (devil's copper). Hierne mentioned it in 1694. Cronstedt was the first chemist who examined it with accuracy. He concluded from his experiments, which were published in the Stockholm Transactions for 1751 and 1754, that it contained a new

metal, to which he gave the name of nickel.

Some chemists, particularly Mr Sage, affirmed, that it contained no new metal, but merely a compound of various known metals, which could be separated from each other by the usual processes. These affections induced Bergman to undertake a very laborious course of experiments, in order if possible to obtain nickel in a state of purity: for Cronstedt had not been able to se. parate a quantity of arfenic, cobalt, and iron, which adhered to it with much obstinacy. These experiments have been very fully detailed in the article CHEMISTRY in the Encycl. to which we beg leave to refer. Bergman has shewn, that nickel possesses peculiar properties, and that it can neither be reduced to any other metal, nor formed artificially by any combination of metals. It must therefore be considered as a peculiar metal. It may possibly be a compound, and so may likewise many other metals; but we must admit every thing to be a peculiar body which has peculiar properties, and we must admit every body to be simple till some proof be actually produced that it is a compound; otherwise we forfake the road of science, and get into the regions of fancy and romance.

Nickel is of a greyish white eolour, and when less Nickel. pure inclines a little to red.

It is both ductile and mallcable. Its hardness is 8 * Its proper-Its specific gravity 9,000 +. It requires for fusion aties, temperature at least equal to 1500 Wedgewood 1.

It is powerfully attracted by the magnet, and is even Miner. ii. It is powerfully attracted by the magnet, and is even possessed of the property of attracting iron. This in the Bergman, duced Bergman to suppose that nickel, when purest, in. 231. was still contaminated with about one third of iron : † Ibid. but as this is the only proof of its containing iron, Klaproth, with reason, deems it an insufficient one, and confiders attraction by the magnet as a property of nickel f. Ann. de

When exposed to a strong heat, nickel is oxydated Chim. i. flowly. Its oxyd is of a brown colour; if impure, it 170. is greenish. The oxyd of nickel, according to Klaproth, Oxyds, is greently. The oxyd of licket, according is composed of 77 parts of nicket and 33 of oxygen ¶. ¶ Kircuan's Miner. ii. Its affinities, according to Bergman, are as follows: 490.

Oxalic acid, Muriatic, Sulphuric, Tartarous, Nitric, Sebacic, Phofphoric, Fluoric, Saccholactic, Succinic, Citric, Formic. Lactic. Acetous. Arfenic, Boracic, Pruffic, Carbonic, Ammonia. Potass? Soda?

Cronstedt found that nickel combined readily with Sulphuret, fulphur by fusion. The fulphuret which he obtained was yellow and hard, with small sparkling facets; but the nickel which he employed was impure.

Nickel combines very readily with phofphorus, either Phofphuby fusing it along with phosphoric glass, or by drep-ret, ping phosphorus into it while red hot. The phosphuret of nickel is of a white colour, and when broke exhibits the appearance of very flender prisms collected together. When heated, the phosphorus burns, and the metal is oxydated. It is composed of 83 parts of nickel and 17 of phosphorus *. The nickel, however, on * Pelletier, which this experiment was made, was not pure.

Little is known concerning the alloys of nickel with Chim. xiii. other metals. Equal parts of filver and nickel form a 135; white ductile alloy. Equal parts of copper and nickel Alloys, form a red ductile alloy. The compounds which this metal forms with tin and zinc are brittle. It does not combine with mercury +. It has a very strong affinity + Bergman, for iron, cobalt, and arlenic, and is scarcely ever found ii. 231. except combined with some of them. - .

Its affinities, according to Bergman, are as follows: And affini-Iron,

Cobalt, Arfenic,

Copper,

Copper, Gold, Tin, Antimony, Platinum, Bismuth, Lead, Silver, Sulphuret of alkali, Sulphur, Phosphorus?

SECT. XV. Of Manganese.

THE dark grey mineral called manganese, in Latin magnesia (according to Boyle, from its relemblance to the magnet), has been long known and used in making glass. A mine of it was discovered in England by Mr Boyle. It was long supposed to be an one of iron; but Pott and Cronfledt having demonstrated that it contained very little of that metal, the latter-referred it in his Mineralogy to a diffinct order of earths, which he called terræ magnesiæ. Bergman, from its specific gravity, and several other qualities, suspected that ic was a metallic oxyd: he accordingly made feveral attempts to reduce it, but without fuccess; the whole mass either affuming the form of fcoriæ, or yielding only fmall feparate globules attracted by the magnet. This difficulty of fusion led him to suspect that the metal he was in quest of bore a strong analogy to platinum. In the mean time, Dr Gahn, who was making experiments on the fame mineral, actually succeeded in reducing it by the following process: He lined a crucible with charcoal powder moistened with water, put into it some of the mineral formed into a ball by means of oil, then filled up the crucible with charcoal powder, luted another crucible over it, and exposed the whole for about an hour to a very intense heat. At the bottom of the crucible was found a metallic button, or rather a number of small metallic globules, equal in weight to onean, third of the mineral employed*. It is eaty to fee by what means this reduction was accomplished. The charcoal attracted the oxygen from the oxyd, and the metal remained behind. This metal is called manganese.

Manganese is of a greyish white colour. It is not malleable, and yet not so brittle as to be easily broken.

Its hardness is 8+. Its specific gravity is 7,000 ‡. Its fusion requires so great a heat, that it has been very feldom accomplished.

When reduced to powder, it is attracted by the

When exposed to the air, it very foon tarnishes, and affumes a darker colour, till at last it becomes black and This change is produced by the absorption of oxygen. It takes place much more rapidly if heat be applied to the metal. The substance thus obtained is the black oxyd of manganese. This oxyd is found in great abundance in nature, though scarcely ever in a state of purity. It is composed of 75 parts of manga-

in, nese and 25 of oxygen *.

If a quantity of muriatic acid be poured upon this Manganese. oxyd, and heat applied, part of the acid combines with fome of the oxygen of the oxyd, and flies off in yellow fumes. The oxyd is diffolved in the rest. If potals be added to this folution, a white powder is precipitated. This is the white oxyd of manganese. It contains, according to Bergman, about 80 parts of manganese and 20 of oxygen. It foon attracts more oxygen when exposed to the air, and is converted into black oxyd.

The affinities of the white oxyd, according to Berg-

man, are as follows:

Oxalic acid, Citric, Phosphoric, Tartarous, Fluoric, Muriatic, Nitric, Saccholactic, Sebacic, Tartaric, Formic, Lactic, Acetous, Pruffic, Carbonic.

The fulphuret of manganese is unknown.

Phosphorus may be combined with manganese by Phosphamelting together equal parts of the metal and of phofiet, photic glass; or by dropping phosphorus upon red hot manganese. The phosphuret of manganese is of a white colour, brittle, granulated, disposed to crystallize, not altered by exposure to the air, and more fusible than manganese. When heated, the phosphorus burns and + Pelletier. the metal becomes oxydated +.

Manganese combines readily with carbon by fu-Ann. de

Little is known concerning the alloys of manganese. It combines readily with copper. The compound, ac. Carburet, cording to Bergman, is very malleable, its colour is red, Alloys, and it sometimes becomes green by age. Gmelin made a number of experiments to fee whether this alloy could be formed by fufing the black oxyd of manganefe along with copper. He partly succeeded, and proposed to substitute this alloy instead of the alloy of copper and arsenic, which is used in the arts t. We believe, how- t Ann. de ever, that upon trial the new alloy has been found not Chim. i. to answer.

Manganese combines readily with iron; indeed it has fearcely ever been found quite free from fome mixture of that metal. It combines also very easily with arfenic and tin, not easily with zinc, and not at all with

The affinities of manganese, according to Bergman, 177 And affiniare as follows:

Copper, Iron, Gold,

Silver,

S Bergman,

(1) Bergman, III. 379 .- Sometimes manganese is very speedily oxydated by exposure to the air; sometimes scarcely altered by it, as Klaproth and Pelletier have observed. Mr Kirwan supposes, that the managanese which is foon altered contains carbon, and that this is the cause of the difference. See Miner. II. 288.

Silver, Sulphuret of alkali, Phosphorus? Carbon?

The three metals, cobalt, nickel, and manganefe, refemble iron in several particulars: Like it, they are magnetic. very hard, and very difficult to fufe: but they differ from it in specific gravity, malleability, and in the properties of all their combinations with other fubstances; the oxyds. for instance of iron, cobalt, nickel, and manganese, possess very different qualities.

SECT. XVI. Of Tungsten.

Difcovery of tingften,

THERE is a mineral found in Sweden of an opaque white colour and great weight; from which last circumstance it got the name of tungslen, or ponderous stone. Some mineralogists considered it as an ore of tin, others supposed that it contained iron. Scheele analysed it in 1781, and found that it was composed of lime and a peculiar earthy-like substance, which he called from its properties tungslic acid. Bergman conjectured that the basis of this acid was a metal; and this conjecture was foon after fully confirmed by the experiments of Messrs D'Elhuyart, who obtained the same substance from a mineral of a brownish black colour, called by the Germans wolfram, which is sometimes found in tin mines. This mineral they found to contain of tungstic acid; the rest of it consisted of manganese, iron, and tin. This acid fubstance they mixed with charcoal powder, and heated violently in a crucible. On opening the crucible after it had cooled, they found in it a button of metal, of a dark brown colour, which crumbled to powder between the fingers. On viewing it with a glass, they found it to consist of a congeries of metallic globules, some of which were as large as a pin head. The metal thus obtained is called tungssen. The manner in which it was produced is evident; tungstic acid is composed of oxygen and tungsten: the oxygen combined with the carbon, and left the metal in a state of purity. Its proper-

Tungsten is externally of a brown colour, internally

* Luyart. of a steel grey *. ‡ Id.

Its specific gravity is 17,600 ‡. It is more infusible

than manganele ||.

When heat is applied to tungsten it is converted into a yellow powder, composed of 80 parts of tungsten and 20 of oxygen; This is the yellow oxyd of tungsten or tung stic acid.

The sulphuret of tungsten is of a bluish black colour,

hard, and capable of crystallizing.

Phosphorus is capable of combining with tungsten 6. Of the alloys of tungten we know nothing, except from the experiments of Elhuyarts, which have been transcribed into the article chemistry in the Encyclopadia; to which, therefore, we beg leave to refer.

SECT. XVII. Of Malybdenum.

Discovery of molybdenuni.

& Pelletier,

Chim. XIII.

Ann. de

₹37.

499

| Id.

+ 1d.

THE Greek word molybdena, and its Latin translation plumbago, feem to have been employed by the ancients to denote various oxyds of lead; but by the moderns they were applied indifcriminately to all substances posfelled of the following properties: Light, friable, and

foft, of a dark colour and greafy feel, and which leave Molyal a stain upon the fingers. Scheele first examined these minerals with attention. He found, that two very different substances had been confounded together. To one of these, which is composed of carbon and iron, and which has been already described, he appropriated the word plumbago; the other he called molybdena.

Part !

Molybdena is composed of scaly particles adhering flightly to each other. Its colour is bluish, very much retembling that of lead. Scheele analysed it, and obtained fulphur and a whitish powder, which possessed the properties of an ac d, and which, therefore, he called acid of molybdena. Bergman first suspected that the basis of this acid was a metal. It was at the request of Bergman and Scheele that Mr Hielm began the laborious courle of experiments by which he lucceeded in obtaining a metal from this acid. His method was to form it into a paste with linfeed oil, and then to apply a very strong heat. This process he repeated several times fuccessively. Klaproth and Pelletier also attempted to reduce it, and with equal fuccets. The metal is molybdenum (K).

Molybdenum is externally of a whitish yellow colour, ste proj

but its fracture is a whitish grey.

Hitherto it has only been procured in small grains,

agglutinated together in brittle maffes.

Its specific gravity is 7,500. It is almost infusible in our fires.

When exposed to a strong heat, it is gradually converted into a whitish coloured oxyd t. When nitric! Pollo acid is poured upon it, molybdenum attracts oxygen, and Popp. is converted into a white oxyd, which possesses the properties of an acid t. This is the molybdic acid.

Molybdenum combines readily with fulphur; and the compound has exactly the properties of molybdena, the fubstance which Scheele decompounded §. Molybdena § Ibil-is therefore fulphuret of molybdenum. The reason that Scheele obtained from it molydic acid was, that the metal combined with oxygen during his process.

Molybdenum is also capable of combining with phof-

phorus *.

Few of the alloys of this metal have been hitherto Chim

It feems capable of uniting with gold. The alloy is probably of a white colour 1.

It combines readily with platinum while in the state Ann of an oxyd. The compound is fulible. Its specific gravity is 20,00 \$.

The alloys of molybdenum with filver, iron, and cop-Ann per, are metallic and friable; those with lead and tin are powders which cannot be futed *.

SECT. XVIII. Of Uranium,

THERE is a mineral found in the George Wagsfort Det mine at Johann Georgenstadt in Saxony, partly in a Difee pure or unmixed state, and partly stratified with other of un kinds of stones and earths. The first variety is of aum. blackish colour inclining to a dark iron grey, of a moderate splender, a close texture, and when broken prefent a somewhat uneven, and, in the smallest particles, a conchoidal surface. It is quite opaque, tolerably hard, and on being pounded yields a black powder. Its specific gravity is about 7,500. The second fort is diftinguished

diffinguished by a finer black colour, with here and there a reddish cast; by a stronger lustre, not unlike that of pitcoal; by an inferior hardnels; and by a shade of green, which tinges its black colour when it is reduced to

This fossile was called pechblende; and mineralogists, misled by the name (L), had taken it for an ore of zinc, till the celebrated Werner, convinced from its texture, hardness, and specific gravity, that it was not a blende, placed it among the ores of iron. Afterwards he suspected that it contained tungslen; and this conjecture was seemingly confirmed by the experiments of fome German mineralogists, published in the Miners Journal t. But Klaproth, whose analyses always difplay the most consummate skill, joined with the most rigid accuracy, examined this mineral about the year 1789, and found that it confided chiefly of fulphur combined with a peculiar metal, to which he gave the name of uranium (M).

Uranium is of a dark grey colour; internally it is

fomewhat inclined to brown 1.

Its hardness is about Its malleability is unknown. 6. It requires a stronger heat for fusion than manganese. Indeed Klaproth only obtained it in very small eonglutinated metallic grains, forming altogether a porous and spongy mass - Its specific gravity is 6,440 ||.

When exposed for some time to a red heat, it suffers no change. By means of nitric acid, however, it may be converted into a yellow powder. This is the yellow oxyd of uranium. This oxyd is found native mixed with the mineral above described. Its affinities have not yet been determined.

Uranium is capable of combining with fulphur. The mineral from which Mr Klaproth first obtained it is a

native sulphuret of uranium.

Nothing is known concerning the alloys or affinities of uranium.

SECT. XIX. Of Titanium.

THERE is a mineral found in Hungary which, from its external appearance, has been called red shorl; but Klaproth, who examined it about the year 1795, difcovered that it confifted chiefly of a peculiar metal, to which he gave the name of titanium.

Titanium is of a brownish red colour, and considerable lustre. It is brittle. Its hardness is 9; its specific

When exposed to a strong heat in a clay crucible, it fuffered no alteration, except that its colour became browner; but in a coal crucible it lost its lustre and broke to pieces.

It is found naturally crystallized in right-angled quadrangular prisms, longitudinally furrowed, and about 1

inch in length.

No acid had any effect in oxydating it; but when mixed with five times its weight of potals, and heated in a porcelain furnace, it melted, and formed when cold

a dense greyish mass, the surface of which was crystal-Telluraum. lized. When diffelved in boiling water, it foon let fall a white powder, weighing about one third more than the titanium employed. This is the oxyd of titanium. Fifty grains of it were reduced by ignition to 38. While hot it was yellowish, but, like oxyd of zine, became white as it cooled. When heated on charcoal, it affumes first a rofy red, and afterwards a slate blue colour, and at last melts into an imperfect bead with a finely striated surface. Mr Klaproth did not succeed in reducing it to the metallic state.

Litanium does not feem to have any affinity for

There was a substance discovered by Mr M'Gregor in Menachathe valley of Menachan in Cornwall, and hence called nite. menachanite. Upon this substance Mr M'Gregor made a very interesting set of experiments, which were published in the Journal de Physique for 1791. He sufpected it to contain a new metal. From its properties,

Mr Kirwan conjectured that it was the same with titanium *; and this conjecture has been very lately con- * Mineral. firmed by Mr Klaproth, who analysed menachanite, andii. 331. found it to be an ore of that metal.

SECT. XX. Of Tellurium.

In the mountains of Fatzbay, near Zalethna in Tran-Difcovery fylvania, there is a mine called Mariahilf; the ore of f telluwhich is wrought for the gold that it contains. Mr Muller of Reichenstein examined it in 1782, and suspected that it contained a new metal; and Bergman, to whom he had fent some of the ore, was of the same opinion: but the quantity of the mineral which these chemists had examined was too inconsiderable to enable them to decide with certainty. Klaproth analysed a larger quantity of it about the year 1797, and found that 1000 parts of it confilled of 72 parts of iron, 2,5 of gold, and 925,5 of a new metal, to which he has given the name of tellurium (N).

Tellurium is of a white colour like tin, approaching Its properfomewhat to the grey colour of lead *.

It is very brittle and friable. Its fracture is laminated. Philosophical Its specific gravity is 6,115. Magazine,

It is as eafily melted as lead. When suffered to cooli. 78. quietly and gradually, it readily assumes a crystallized + Muller.

When heated by the blowpipe upon charcoal, it burns with a very lively flame of a blue colour, inclining at the edges to green. It is fo volatile as to rife entirely in a whitish grey smoke; at the same time it exhales a disagreeable odour like that of radishes. This smoke is the white oxyd of tellurium, which may be formed also by diffolving the metal in nitro-muriatic acid, and pouring into the faturated folution a quantity of water: a white powder precipitates, which is the oxyd ‡. ‡ Klaproths

When this oxyd is heated for some time in a retort, it melts, and appears, after cooling, of a yellow straw colour, having acquired a fort of radiated texture. When

formed

(L) Blende is the name given to ores of zinc.

(M) From Uranus (Cugaris), the name given by Mr Bode to the new planet discovered by Herschel; which name the German astronomers have adopted. Mr Klaproth called the metal at first uranite; but he afterwards changed that name for uranium.

(N) Mr Kirwan, in the new edition of his Mineralogy, which was published before Mr Klaproth's experiments were known, gives this metal the name of Sylvanite. - Tellurium exists in several other mines in the same

(o) From χεωμα, because it possesses the property of giving colour to other bodies in a remarkable degree. (r) W. Wedgewood's pyrometer. F. Fahrenheit's thermometer.

we have feen that all the metals are capable of combining with oxygen; that almost every one forms various oxyds, containing different quantities of oxygen, allie and varying in colour and other properties according to the proportion of oxygen which they contain. No part of chemistry has more engaged the attention of philofophers than the metallic oxyds; and yet such is the difficulty of the subject, that scarcely any part of chemistry is more imperfectly understood.

We neither know how many oxyds every particular metal is capable of forming, nor the manner in which they are formed: neither have the differences between oxyds of the fame metallic base been enquired into; though there cannot be a doubt that they differ, not only in their affinities, but in many of their other properties. The white oxyd of manganese, for instance, combines readily with acids, but the black is incapable

of uniting with any.

Mr Proust, in a very valuable paper which he lately published concerning the oxyds of iron *, hints that xxiii. metals are only capable of two degrees of oxydation, or, which is the fame thing, that only two different oxyds can be produced from the fame metal. We think he has proved this completely as far as iron is concerned; and probably the observation holds good with respect to many other metals. Arfenic, copper, tin, molybdenum, and perhaps even mercury, seem to be capable of only two degrees of oxydation; but it would require a very numerous and accurate fet of experiments to be able to determine the matter, or even to form a probable conjecture. Analogy is certainly against the supposition; for it has been demonstrated that some subflances at least are capable of combining with three different doses of oxygen (Q), and why may not this be the case also with the metals?

There is one observation, however, which we owe to Mr Proust, the truth of which cannot be doubted, and which is certainly of the highest importance-that metals are not capable of indefinite degrees of oxydation, but only of a certain number; and that every particular oxyd confifts of a determinate quantity of the metal and of oxygen chemically combined. Iron, for instance, is not capable, as has been supposed, of uniting with oxygen in all the intermediate degrees between 27 and 43, and consequently of forming 20 or 30 different oxyds; it can only combine with precisely 17,00 parts, or 48 parts, and with no other proportions; and therefore is only capable of forming two oxyds, the green and the brown. In like manner, every other metal combines with certain proportions of oxygen, and forms either two oxyds or more according to its nature. To talk therefore of oxydating a metal indefinitely is not accurate, except it be intended to fignify the combining of part of it with oxygen, while the rest remains in its natural state. If iron be oxydated at all, it must be combined with $\frac{27}{100}$ of oxygen; if it be oxydated more than this, it must be combined with 48 of oxygen.

We beg leave to add another observation, which we consider as of no less importance, and which will serve in some measure to modify and explain what has been just now said. Oxygen is capable of uniting with me-

SUPPL. VOL. I. Part I.

tals, or with any other fubstance for which it has an Tellurium. affinity, only in one determinate proportion. Iron, for instance, and oxygen can only combine in the proportion of 73 parts of iron and 27 of oxygen. These two quantities faturate each other, and form a compound which is incapable of receiving into it any more oxygen or iron: this compound is the green oxyd of iron. How comes it then, it will be asked, that there is another oxyd of iron, the brown oxyd, which contains 52 parts of iron and 48 of oxygen, proportions certainly very different from 73 and 27? We answer, there is an affinity between the green oxyd of iron and oxygen; they are capable of combining together, and of faturating each other in the proportion of about 71,5 parts of green oxyd and 28,5 of oxygen; and the compound which they form is the brown oxyd, which of course contains 52 parts of iron and 48 of oxygen: But then it is not formed by the combination of these two substances directly, but by the combination of the green oxyd and oxygen. In like manner, the arfenic acid is not composed of arsenic and oxygen combined directly, but of white oxyd of arfenic combined with oxygen. The very fame thing takes place in all the other metals. We cannot at present prove the truth of this observation in a fatisfactory manner, because it would be neceffary to draw our proofs from combinations which are yet undiscribed; but we will have occasion to consider it afterwards.

We have feen, that all the metals hitherto tried are capable of combining with fulphur, except gold and titanium; that all of them on which the experiments have been made can be united with phosphorus; and that three of them, iron, zinc, and manganese, united with carbon; and perhaps many more of them may hereafter be found capable of assuming the form of car-

We have feen, too, that they are capable of uniting with one another and forming alloys. This was long reckoned peculiar to metals, and it is at prefent one of the best criterions for determining the metallic nature of any substance. Much is wanting to render the chemistry of alloys complete. Many of them have never been examined; and the proportions of almost all of them are unknown. Neither has any accurate method been yet discovered of determining the affinities of metals for each other. The order of affinities which we have given for each metal was determined by Bergman; but he acknowledged himself that he wanted the proper data to ensure accuracy.

CHAP. IV. Of EARTHS.

The word earth, in common language, has two meanings; it fometimes fignifies the glove which we inhabit, and fometimes the mould on which vegetables grow. Chemifts have examined this mould, and have found that it confifts of a variety of fubflances mixed together without order or regularity. The greatest part of it, however, as well as of the stones, which form apparently so large a proportion of the globe, consists of a small number of bodies, which have a variety of common properties.

Lime

perties. These bodies chemists have agreed to class together, and to denominate earths.

Every body which possesses the following properties

is an earth: 192

Properties of earths.

1. Infoluble in water, or nearly fo; or at least becoming infoluble when combined with carbonic acid.

2. Little or no taste or smell; at least when com-

bined with carbonic acid.

3. Incombustible, and incapable while pure of being altered by the fire.

4. A specific gravity not exceeding 4,9.

5. When pure, capable of affuming the form of a white powder.

The earths at prefent known amount to nine; the names of which are, lime, magnefia, barytes, strontites,

alumina, filica, jargonia, adamanta, glucina.

Every one of the above characteristics is not perhaps rigorously applicable to each of these bodies; but all of them possess a sufficient number of common properties to render it useful to arrange them under one class.

SECT. I. Of Lime.

LIME has been known from the earliest ages. The ancients employed it in medicine; it was the chief ingredient in their mortar; and they used it as a manure to fertilize their fields.

Method of procuring lime.

194 Properties

of lime.

It abounds in many parts of the world, or perhaps we should rather say, that there is no part of the world where it does not exist. It is found purest in limeftones, and marbles and chalk. None of these substances, however, is, strictly speaking, lime; but they are all capable of becoming lime by a well-known process, by keeping them for fome time in a white heat: this process is called the burning of lime; the product is denominated quicklime. This last fubstance is what we call lime.

Pure lime is of a white colour, moderately hard, but

eafily reduced to a powder.

It has a hot burning tafte, and in fome measure corrodes and defroys the texture of those animal bodies to which it is applied. It has no fmell. Its specific gra-

*Kirwan's vity is 2,3 *. Miner. i. 5.

If water be poured on newly burnt lime, it fwells and falls to pieces, and is foon reduced to a very fine powder. In the mean time, fo much heat is produced, that part of the water flies off in vapour. If the quantity of lime flacked (as this process is termed) be great, the heat produced is sufficient to set fire to combustibles. In this manner, veffels loaded with lime have fometimes been burnt. When great quantities of lime are flacked in a dark place, not only heat, but light also is emitted, as Mr Pelletier has observed f. When slacked lime is Phys. t. 22. weighed, it is found to be heavier than it was before. This additional weight is owing to the combination of part of the water with the lime; which water may be feparated again by the application of a red heat; and by this process the lime becomes just what it was before

| Dr Black being flacked | .

Six hundred parts of water, at the temperature of Lime-wa-60°, diffolve about one part of lime; boiling hot water * Kirwan's dissolves about double that quantity *. This folution Miner. i. 5. is called lime-water. It is limpid, has an aerid tafte, and changes vegetable blue colours to green. One ounce troy of lime-water contains about one grain of

One thousand parts of lime are capable of absorbing, and retaining, at a heat of 600°, 228 parts of water \$

Lime has never yet been obtained in the state of Lavolin

It is incapable of being fused by the most violent heat that can be produced in furnaces, or even by the most powerful burning glaffes.

Lime unites readily with fulphur, and forms fulphures Sulphures of lime. This compound may be obtained by mixing and unflacked lime and flowers of fulphur together, and adding a little water. The heat produced by the flacking of the lime is sufficient to make the fulphur and the lime unite. This sulphuret is of a red colour. When water is poured on it, fulphurated hydrogen gas is emitted. The fulphur is gradually converted into fulphuric acid by uniting with the oxygen of the water, the hydrogen of which flies off in the form of gas, diffolving at the same time a part of the sulphur.

It is capable also of combining with phosphorus .- Phospher The phosphuret of lime decomposes water by the affist-of lime, ance of a moderate heat, and gives out phosphurated

hydrogen gas.

Limestone and chalk, though they are capable of be-Cause of ing converted into lime by burning, possess hardly any the diffe-of the properties of that active substance. They are rence betalleless, scarcely soluble in water, and do not percep-tweenlim tibly act on animal bodies. Now, to what are the new lime, properties of lime owing? What alteration does it un-

dergo in the fire?

It had been long known, that limestone loses a good deal of weight by being burned or calcined. It was natural to suppose, therefore, that something was separated from it during calcination. Accordingly, Van Helmont, Ludovicus, and Macquer, made experiments in fuccession, in order to discover what that famething was; and they concluded from them that it was pure water, which the lime recovered again when exposed to the atmosphere. As the new properties of lime could hardly be ascribed to this loss, but to some other cause, According Stahl's opinion, like all the other chemical theories of to Stahl; that wonderful man, was generally acceded to. He supposed that the new properties which lime acquired by calcination, were owing entirely to the more minute division of its particles by the action of the fire. Boyle indeed had endeavoured to prove, that these properties. were owing to the fixation of fire in the lime: a theory which was embraced by Newton and illustrated by Hales, and which Meyer new modelled, and explained with so much ingenuity and acuteness as to draw the attention of the most distinguished chemists. But while Meyer was thus employed in Germany, Dr Black of Edinburgh published those celebrated experiments which form to brilliant an era in the history of chemistry.

He first ascertained that the quantity of water sepa-Explained rated from limestone during its calcination was not near-by Dr Black ly equal to the weight which it loft. He concluded in consequence, that it must have lost something else than mere water. What this could be, he was at first at a loss to conceive; but recollecting that Dr Hales had proved, that limestone, during its folution in acids, emitted a great quantity of air, he conjectured that this might probably be what it loft during calcination. He calcined it accordingly, and applied a pneumatic apparatus to receive the product. He found his conjecture

verified;

Lime.

ted from the lime, were together precifely equal to the lofs of weight which it had fuftained. Lime therefore owes its new properties to the lofs of air; and limestone differs from lime merely in being combined with a certain quantity of air: for he found that, by reforing again the same quantity of air to lime, it was converted into limestone. This air, because it existed in lime in a fixed state, he called fixed air. It was afterwards examined by Dr Priesley and other philosophers, found to possetis peculiar properties, and to be that species of gas now known by the name of carbonic acid gas. Lime then is a simple substance, that is to fay, it has never yet been decompounded; and limestone is composed of carbonic acid and lime. Heat separates the carbonic acid, and leaves the lime in a state of purity.

The affinities of lime, according to Bergman, are as

follows:

covery

Oxalic acid, Suberic (R)? Sulphuric, Tartarous, Succinic, Phosphoric, Saccholactic, Nitric, Muriatic, Sebacic, Fluoric, Arfenic, Formic, Lactic, Citric, Benzoic, Sulphurous, Acetous, Boracic, Nitrous, Carbonic, Pruffic, Sulphur, Phosphorus, Water, Fixed oil.

SECT. II. Of Magnefia.

ABOUT the beginning of the eighteenth century, a Roman canon exposed a white powder to fale at Rome as a cure for all difeafes. This powder he called magnesia alba. He kept the manner of preparing it a profound secret; but in 1707 Valentini informed the publie that it might be obtained by calcining the lixivium which remains after the preparation of nitre; and two

verified; and that the air and the water which separa- years after, Slevogt discovered that it might be preci- Magnesia. pitated by potass from the mother ley (s) of common falt. This powder was generally supposed to be lime, till Frederic Hoffman observed that it formed very different combinations with other bodies *. But little was * Bergman, known concerning its nature till Dr Black published his i 365. celebrated experiments in 1755. Margraf published a differtation on it in 1759, and Bergman another in 1775 in which he collected the observations of these two philosophers, and which he enriched also with many additions of his own.

As magnefia has never yet been found native in a Method of state of purity, it may be prepared in the following procuring manner: Sulphat of magnefia, a falt composed of this it. earth and fulphuric acid, exitts in fea water, and in many fprings, particularly force about F.pfom, from which circumstance it was formerly called Epjom falt This falt is to be diffolved in water, and half its weight of potass added. The magnesia is immediately precipitated, because potass has a stronger affinity for sulphuric acid. It is then to be washed with a sufficient quanity of water, and dried.

Magnefia thus obtained is a very foft white powder, its properwhich has very little taste, and is totally destitute of the fmell .- Its specific gravity is about 2,3 §.

It is foluble in about 7900 times its own weight of Miner. i. 8. water at the temperature of 60° ||.

Even when combined with carbonic acid (for which it has a strong affinity) it is capable of absorbing and retaining 15 times its own weight of water, without letting go a drop; but on exposure to the air, this water evaporates, though more flowly than it would from lime.

Magnefia has never yet been obtained in a crystallized

It tinges vegetable blues of an exceedingly flight

SECT. III. Of Barytes.

Discovery

A very heavy mineral is found in Sweden, Germany, and Britain, which Margraf confidered as a compound of fulphuric acid and lime. But Scheele and Gahn analysed it in 1774, and found that it consisted of fulphuric acid combined with a peculiar species of earth. This analysis was soon after confirmed and extended by Bergman. The earth was at first called terra ponderosa, heavy earth, on account of the great specific gravity of the substance from which it was obtained. Morveau called it barote (from Capus, beavy), which Bergman changed into barytes; and this last term is now univerfally adopted.

Barytes is generally found combined either with ful- Barytes phuric or carbonic acid. From the first of these compounds, which is by far the most common, it may be Method obtained by the following process:

Reduce the mineral to a powder, and mix it with 21, it. its weight of carbonat of foda (T), previously deprived of all its water. Expose the mixture to a red heat for an hour and a half, avoiding fusion, and a double decomposition takes place; the sulphuric acid unites with the foda, while the carbonic acid combines with the barytes. Wash it in a sufficient quantity of water to dissolve the compound of fulphuric acid and foda, the carbonat of barytes, which is almost insoluble, remains behind. Least it should be mixed with some other earths, which is generally the case, boil it for three hours in ten times its weight of diffilled vinegar, the specific gravity of which is 1,033; by which the barytes will be diffolved, and likewise the lime and magnesia, if there happen to be any; but every other earth (u) remains untouched. Pour off the folution, and add to it fulphuric acid as long as any precipitate is formed. This precipitate confilts of the whole barytes and the lime (if there be any) combined with fulphuric acid. Wash it in 50 times its weight of water, and all the lime will be diffolved. There will now remain nothing but barytes combined with fulphuric acid, which may be decomposed as before by carbonat of foda f. The carbonic acid may then be sepa- & Asauc rated by applying a very violent heat +; or, what is Arm. de better, aitric acid may be poured upon it, which will Hope, feparate the carbonic acid and combine with the ba-Edin. Tr rytes; and then the nitric acid may be driven off by aiv. 36. moderate heat §.

Barytes thus obtained is a light, fpongy, porous, bo. and Vau dy, which may be very eafily reduced to powder. It lin, Ann. has a harsh and more caustic taste than lime; and when 276. taken into the stomach, proves a most violent poison. Its propo

It has no perceptible fmell.

Its specific gravity has not yet been ascertained. ties. It imbibes water with a hiffing noise, but, according to Dr Hope, without fwelling or fplitting as lime does ||. However, when exposed to the air, as Four- || Edin.

croy and Vauquelin inform us, it effloresces, cracks, Trans. it burfts, fwells up, heats, and becomes white, by abforbing moisture f.

Cold water diffolves about 1 part of its weight of Chim. ibi barytes, and boiling water more than half its weight. and Nic As the water cools, the barytes is deposited in crystals, i. 535. the shape of which varies according to the rapidity with which they have been formed. When most regular, they are flat hexagonal prifms, having two broad fides, with two intervening narrow ones, and terminated at each end by a four-fided pyramid, which in some instances constitutes the larger part of the crystal. When formed slowly, they are distinct and large; but when the water is faturated with barytes, they are depolited rapidly, and are generally more slender and delicate. Then, too, they are attached to one another in such a manner as to assume a beautiful foliacious appearance, not unlike the leaf of a fern ¶.

These crystals are transparent and colourless, and appear to be composed of about 53 parts of water and 47

(T) Soda is an alkali; which shall be afterwards described. Carbonat of soda is soda combined with carbonic acid, the common state in which it is obtained; potass might also be used. (v) Except strontites, which Pelletier has detected in this mineral.

Mope, il

of barytes. When exposed to the heat of boiling water, they undergo the watery fufion, or, which is the fame thing, they melt without lofing any of the water which they contain. A stronger heat makes the water fly off. When exposed to the air, they attract carbonic acid, and crumble into dust. They are soluble in 17: parts of water at the temperature of 60°; but boiling water diffolves any quantity whatever: the reason of which is evident; at that temperature their own water of crystallization is sufficient to keep them in solu-

Water faturated with barytes is called barytic avater. It has the property of converting vegetable blues to a

When barytes is exposed to the blow-pipe on a piece of charcoal, it fuses, bubbles up, and runs into globules, which quickly penetrate the charcoal ‡. This is proque-bably in confequence of containing water; for Lavoisier found barytes not affected by the throngest heat which

he could produce. Barytes combines readily with fulphur. The easiest es. way of forming fulphuret of barytes is to mix eight parts of fulphuret of barytes with one part of pounded chercoal and to apply a strong heat. The charcoal combines with the oxygen of the fulphuric acid, and the compound flies off in the form of carbonic acid gas. There remains behind fulphur combined with barytes. Sulphuret of barytes is foluble in water: It is of a yellow colour. It is capable of crystallizing; and then roy. assumes a yellowish white colour ||.

The phosphuret of barytes has not been examined.

No mixture of barytes and lime, nor of barytes and magnefia, is fufible in the strongest heat which it has her, been possible to apply J.

The affinities of barytes, according to Bergman, are

as follows:

Sulphuric acid, Oxalic, Succinic, Fluoric, Phosphoric, Saccholactic, Suberic (v)? Nitric, Muriatic, Sebacic, Citric, Tartarous. Arfenic, Fluoric, Lactic, Benzoic, Acetous, Boracic, Sulphurous, Nitrous, Carbonic, Pruffic, Sulphur, Phosphorus, Water, Fixed oils.

SECT. IV. Of Strontites.

Amour the year 1787, a mineral was brought to Difcovery Edinburgh, by a dealer in fossils, from the lead mine of of stron-Strontian in Argyleshire, where it is found imbedded tites. in the ore, mixed with feveral other fubitances. It is fometimes transparent and colourless, but generally has a tinge of yellow or green. Its hardness is 5. Its specific gravity varies from 3.4 to 3,726. Its texture is generally fibrous; and fometimes it is found crystallized in stender prismatic columns of various lengths I. \$ Hope, E-

This mineral was generally confidered as a carbonat din. Tranf. of barytes; but Dr Crawford having observed some iv. 44. differences between its folution in muriatic acid and that of barytes, mentioned in his treatife on muriat of barytes, published in 1790, that it probably contained a new earth, and fent a specimen to Mr Kirwan that he might examine its properties. Dr Hope had also suspected that its basis differed from barytes; and accordingly he made a fet of experiments on it in 1791, which were read to the Royal Society of Edinburgh in 1792. These experiments fully proved that it contained a peculiar earth. Mr Kirwan likewife analyfed the strontian mineral, and drew precifely the fame conclusions. It has been analysed also by Mr Klaproth of Berlin, and Mr Pelletier of Paris. It confifts of carbonic acid combined with a peculiar earth, to which Dr Hope gave the name of strontites. This appellation we shall adopt.

The carbonic acid may be feparated by a heat of 140° Wedgewood, and then the firontites remains be-* Kiravan's hind *.

Strontites has been found in Argyleshire in Scot-Miner. i. land, near Bristol in England, and in Pennsylvania +. It 332. has been found also in France and in Sicily. It is of a ii. sect. 39. white colour. It has a pungent acrid tafte. When white colour. It has a pungent active traces the proper-pounded in a mortar, the powder that rifes is offensive its properto the nostrils and lungs t. It is not poisonous ||.

One hundred and fixty two parts of water, at the | Pelletier. temperature of 60°, dissolve nearly one part of it. The solution is clear and transparent, and converts vegetable blues to a green. Hot water dissolves it in much larger quantities; and as it cools the strontites is deposited in colourless transparent crystals. These are in the form of thin quadrangular plates, generally parallelograms, the largest of which seldom exceeds one fourth of an inch in length. Sometimes their edges are plain, but they oftener confift of two facets, meeting together and forming an angle like the roof of a house. These crystals generally adhere to each other in such a manner as to form a thin plate of an inch or more in length and half an inch in breadth. Sometimes they assume a cubic form. They contain about 68 parts in 100 of water. They are soluble in 51,4 parts of water, at the temperature of 60°. Boiling water dissolves nearly half its weight of them. When exposed to the air, they lose their water, attract carbonic acid, and fall into powder*.

When strontites is thrown into water, it attracts it with a hiffing noise, much heat is produced, and it falls into powder much more rapidly than lime +.

It combines with fulphur either by fution in a crucible, or by being boiled with it in water. The fulphuret

Par

Silica. phuret is of a dark yellowish brown colour. It is soluble in water ‡.

The affinities of strontites, as afcertained by Dr Hope, to affini- are as follows:

SECT. V. Of Silica.

Method of obtaining filica.

Is one part of powdered flints or fand, mixed with three parts of potafs, be put into a crucible, and kept in a flate of fusion for half an hour, a brittle mass will be formed almost as transparent as glass, which quickly attracts moisture from the atmosphere, and is entirely soluble in water. This solution is called liquor filicum, or liquor of flints. It was first accurately described by Glauber, a chemist who lived about the middle of the 17th century.

If an acid be poured into this liquor, a white spongy substance is precipitated, which may be purified from every accidental mixture by washing it in acids, muriatic acid for instance. This substance is called siliceous earth or silica. It was first distinguished as a peculiar earth by Pott in 1746, though it had been known long before; and Cartheuser, Scheele, and Bergman proved in succession that it could not, as some chemists had sup-

posed, be reduced to any other earth.

Its proper- Silica, when dried, is a soft white

- Silica, when dried, is a foft white powder, without

ies. either tafte or fmell.

*Kiravan's Its specific gravity is 2,66 *.

It is infoluble in water except when newly precipitated from the liquor filicum, and then one part of it is foluble in 1000 parts of water †. It has no effect on vegetable colours.

It is capable of abforbing about one-fourth of its weight of water, without letting any drop from it; but on exposure to the air, the water evaporates very

\$ Ibid. readily ‡.

+ Ibid.

Silica may be formed into a paste with a small quantity of water: this paste has not the smallest ductility, and when dried forms a loose, friable, and incoherent

§ Scheele. mafs f.

Silica is capable of affurning a crystalline form. Crystals of it are found in many parts of the world. They are known by the name of rock crystal. When pure they are transparent and colourless like glass: they assume various forms; the most usual is a hexagonal prism, surmounted with hexagonal pyramids on one or both ends, the angles of the prism corresponding with those of the pyramids. Their hardness is very great,

** Kirwan's amounting to eleven. Their specific gravity is 2,653*.

There are two methods of imitating these crystals by art— I'he first method was discovered by Bergman. He dissolved silica in sluoric acid, the only acid in which it is soluble, and allowed the solution to remain undissurbed for two years. A number of crystals were then found at the bottom of the vessel, mostly of irregular figures, but some of them cubes with their angles truncated. They were hard, but not to be compared in this respect with rock crystal *.

The other method was discovered by accident. Pro-ii 32. seeffor Seigling of Erfurt had prepared a liquor filicum, which was more than usually diluted with water, and contained a superabundance of alkali. It lay undisturbed for eight years in a glass vessel, the mouth of which was only covered with paper. Happening to look to it by accident, he observed it to contain a number of crystals; on which he fent it to Mr Trommsdorff, professor of chemistry at Erfurt, who examined it. The liquor remaining amounted to about two ounces. Its furface was covered by a transparent cruft, so strong that the veffel might be inverted without spilling any of the liquid. At the bottom of the veffel were a number of crystals, which proved on examination to be sul phat of potals and carbonat of potals (w). The crust on the top confifted partly of carbonat of potals, partly of crystallized silica. These last crystals had assumed the form of tetrahedral pyramids in groups; they were perfeetly transparent, and so hard that they struck fire with steel +.

Silica endures the most violent heat without altera-Jon's Jun

tion.

It feems incapable of combining with fulphur or phosphorus.

1. The effect of heat upon lime and filica, mixed in Effect of various proportions, will appear from the following exhaut on periments of Mr Kirwan ‡.

1								
Proportions.	Heat.	Effect.						
50 Lime 50 Silica	150° Wedg.	Melted into a mass of a white colour, semitrans parent at the edges, and striking fire, tho' feebly, with steel: it was somewhat between porcelain and enamel.						
80 Lime 20 Silica	156	A yellowish white loose powder.						
20 Lime 80 Silica	156	Not melted, formed a brittle mass.						

2. Equal parts of magnefia and filica melt with great Magnefic difficulty into a white enamel when exposed to the most and fills violent heat which can be produced *. They are infu-*Lassiff fible in inferior heats in whatever proportion they are Mem P mixed †.

3. The effect of heat on various mixtures of barytes ⁵⁹⁸, and filica will appear from the following experiments of Barytes Mr Kirwan ‡.

Proportions.

(w) Potafs, combined with fulphuric acid and with carbonic acid.

1. 371

56.

Propostions.	Heat.	Effect.
80 Silica 20 Barytes	155° Wedg.	A white brittle mass.
75 Silica 20 Barytes	150	A brittle hard mass, semi- transparent at the edges.
66 Silica 33 Barytes	150	Melted into a hard fome- what porous porcelain mass.
50 Silica 50 Barytes	148	A hard mass not melted.
20 Silica 80 Barytes	148	The edges were melted into a pale greenish matter between a porcelain and enamel.
25 Silica 75 Barytes	150	Melted into a formewhat porous porcelain mass.
33 Silica 66 Barytes	150	Melted into a yellowish and partly greenish white porous porcelain.

4. The effect of heat on mixtures of strontites and filica is not known.

5. It follows from the experiments of Achard, that equal parts of lime, magnefia, and filica, may be melted into a greenish coloured glass, hard enough to strike fire with fteel; that when the magnefia exceeds either of the other two, the mixture will not melt; that when the filica exceeds, the mixture feldom melts, only indeed with him in the following proportions; three filica, two lime, one magnefia, which formed a porcelain; and that when the lime exceeds, the mixture is generally fude fible *.

The affinities of filica are as follows: Fluoric acid, Fixed alkali.

SECT. VI. Of Alumina.

DISSOLVE alum in hot water, and add to the folution potass as long as any precipitate is formed. Decant off the fluid part, and wash the precipitate in a fufficient quantity of water, and then allow it to dry. The fubstance thus obtained is called alumina. Its properties were first ascertained with accuracy by Margraf.

Alumina thus obtained is a very white spongy pow-

er- der, without any smell or taste.

Its specific gravity is 2,00+. It is scarcely soluble in i. 9. water, but may be diffused through it with great facility.

With a finall quantity of water it forms a very tough Alumina. ductile paste, and does not readily mix with more.

In its usual state of drynels it is capable of absorbing 21 times its weight of water, without fuffering any to drop out. It retains this water more obstinately than any of the earths hitherto described. In a freezing cold it contracts more, and parts with more of its water than any other earth; a circumstance which is of some importance in agriculture *.

Alumina has never yet been obtained in a crystallized form. It has no effect whatever on vegetable co-

lours.

The most intense heat does not fuse it, but it has the fingular property of diminishing in bulk in proportion to the intenfity of the fire to which it is exposed. It becomes at the same time exceedingly hard: Mr Lavoisier rendered it capable of cutting glass; and Mr Boyle had long before done the same thing*.

Wedgewood took advantage of this property of alu-Boyle, iii. mina, and by means of it constructed an instrument for 422. measuring high degrees of heat. It consists of pieces Wedgeof clay of a determinate fize, and an apparatus for mea-wood's furing their bulk with accuracy: One of these pieces is thermoput into the fire, and the temperature is estimated by meter. the contraction of the piece. For a more complete description of this important instrument, we refer to the article THERMOMETER in the Encycl.

Alumina is hardly susceptible of combining with sulphur or phorphorus; but from the experiments of La Grange, it appears to have an affinity for carbon ‡.

I. The effect of heat on various mixtures of lime and fon's Jour. alumina will appear from the following table §.

i. 56. Effect. Heat. Proportions. Effect of heat on mixtures of 75 Lime 150° Wedg. Not melted. 25 Alumina 66 Lime Remained a powder. 150 33 Alumina 33 Lime Melted. 66 Alumina 25 Lime Melted. (x) 75 Alumina 20 Lime Melted. (x)80 Alumina

2. Magnefia and alumina have no action whatever on each other, even when exposed to a heat of 1500 Wedge-Magneña

	20 Alumina 80 Barytes	148	Somewhat harder, but no fign of fusion.
The state of the s	25 Alumina 75 Barytes	150	Harder, but no fign of fusion.

4. Nothing is known concerning the effect of heat on mixtures of strontites and alumina.

5 Equal parts of alumina and filica harden in the * Kirwan's temperature of 160° Wedgewood, but do not fuse *. Min. 1. 58. Achard found them infusible in all proportions in a heat probably little inferior to 150° Wedgewood. Mixtures of these two earths in various proportions form clays, but these are seldom uncontaminated with some other ingredients.

229 6. From the experiments of Achard, it appears that Lime, mag-no mixture of lime, magnefia, and alumina, in which the lime predominates, is vitrifiable, except they be nearly in the proportions of three lime, two magnefia, one alumina; that no mixture in which magnefia predominates will melt in a heat below 1660; that mixtures in which the alumina exceeds are generally fufible, as will appear

† Ibid. i. 72. from the following table †:

Name and Address of the Address of t	
3 Alumina 2 Lime 1 Magnesia	A porcelain.
3 Alumina 1 Lime 2 Magnefia	A porcelain.
3 Alumina 1 Lime 3 Magnesia	Porous porcelain.
3 Alumina 2 Lime 3 Magnefia	Porous porcelain.
3 Alumina 2 Lime 2 Magnefia	Porcelain.

230 7. From the same experiments, and those of Kirwan, ca, and alu-we learn, that, in mixtures of lime, filica, and alumina,

either into a glass or a porcelain, according to the pro- Almi portions. The only infusible proportions were,

3 Lime Silica Alumina

That if the filica exceeds, the mixture is frequently fufible into an enamel or porcelain, and perhaps a glass; and that when the alumina exceeds, a porcelain may often be attained, but not a glasst.

8. As to mixtures of magnefia, filica, and alumina, 231 when the magnefia exceeds, no fusion takes place at Magne 150°. When the silica exceeds, a porcelain may often alumin be attained; and three parts filica, two magnefia, and one alumina, formed a glass. When the alumina exceeds, nothing more than a porcelain can be produced *.

9 Achard found that equal parts of lime, magnefia, 232 filica, and alumina, melted into a glass. They fused al-Andlin fo in various other proportions, especially when the filica magnet predominated. alumiz

The affinities of alumina are as follows:

Sulphuric acid. Nitric, Muriatic, Oxalic, Arlenic, Fluoric, Sebacic, Tartarous, Succinic, Saccholactic. Citric, Phosphoric, Formic, Lactic, Benzoic, Acetous. Boracic, Sulphurous, Nitrous. Carbonic, Pruffic.

SECT. VII. Of Jargonia.

Among the precious stones which come from the Different island of Ceylon, there is one called jargon, which is of jargo possessed of the following properties.

Its colour is various, grey, greenish white, yellowish, reddish brown, and violet. It is often crystallized, either in right angular quadrangular prisms surmounted with pyramids, or octahedrals confifting of double quadrangular pyramids. It has generally a good deal of lustre, at least internally. It is mostly semitransparent. Its hardness is from 10 to 16: Its specific gravity from 4,416 to 4,7 *. * Thid, i

It loses scarcely any of its weight in a melting heat; 333. for Klaproth found that 300 grains, after remaining in it for an hour and a half, were only one-fourth of a grain lighter than at first +. Neither was it attacked either + Jour. by muriatic or fulphuric acid, even when affifted by heat. Phys. 30 At last, by calcining it with a large quantity of soda, 180. he dissolved it in muriatic acid, and found that 100 parts when the lime exceeds, the mixture is generally fufible of it contained 31,5 of filica, five of a mixture of nick-

Viral.

1.4.

6

very

d tanta. el and iron, and 68 of an earth possessed of peculiar properties. This earth has been called jargonia.

Jargonia has a strong refemblance to alumina. It is of a white colour. Its specific gravity probably exceeds 4,000.

It differs from alumina in the compounds which it forms with other bodies, in being infoluble in a boiling folution of pure potals or foda, and in being infulible by heat when mixed with these substances in a state of I wan's dryness t.

No more of its properties are yet known.

SECT. VIII. Of Adamanta.

THERE is a stone found in China and in the East Inman-dies near Bombay, which from its hardness has been called adamantine spar. Mr Greville first received some specimens of it, and made it known to several French and English naturalists.

The variety which comes from China is crystallized in hexagonal prisms. It is of a grey colour. The entire pieces are opaque, but thin plates of it are transparent. It is fo hard, that it not only cuts glass as easily as the diamond, but even fcratches rock crystal and many other very hard stones. Its specific gravity is 3,710. The variety which comes from Bombay, and which is

A de Mr Greville fent some specimens of this Mr Greville fent some specimens of this stone to Mr Klaproth, that he might analyse it: a task which he found very difficult to perform, for the common proceffes had no effect upon it. At last he succeeded by fuling it 12 times in a filver crucible with 15 parts of foda, and exposing it each time for five hours to the ftrongest heat which the crucible could endure. After each fusion he softened the mass with boiling water, precipitating by acids the earth which the foda had diffolved. He digested also different times the undecomposed part in boiling acids. By this process he decomposed it, and found that it was composed of two parts of alumina, and one of a peculiar earth which has been called adamanta.

This earth he at first took for silica; but it differs from it in not being infufible when mixed with potass rwan's or foda. Its specific gravity probably exceeds 3,00 +. Nothing more is known concerning its properties.

A NEW earth has lately been discovered by Mr Vauquelin in the beryl, to which he has given the name of glucina. His account of its properties we have not hitherto been able to procure: we must therefore reserve our description of it till we come in the order of the alphabet to the word GLUCINA.

These are all the simple earths hitherto discovered; for Sidneia (Y), which was announced by Mr Wedgewood as a peculiar earth, has lately been proved by Mr Hatchet * to be merely a mixture of feveral earths which

have been long known.

ineia.

arks

The first four earths have a great many common properties: they tinge vegetable blues green, they have a SUPPL. VOL. I. Part I.

firong affinity for carbonic acid, and combine readily Adamanta. with all acids. They have fometimes been called alka-

There is a strong resemblance between filica and ada-

manta, and between alumina and jargonia.

None of the earths have been hitherto decompounded, nor has the smallest proof ever been brought that they are compounds. We must therefore, in the present state of chemistry, consider them as simple bodies. Many attempts, indeed, have been made to shew that there was but one earth in nature, and that all others were derived from it. The earth generally made choice of as the simplest was silica (z). But none of these attempts, notwithstanding the ingenuity of several of the authors, has been attended with the smallest shadow of

We have mentioned formerly, that it was almost the universal opinion of chemists that metals were composed of some of the earths united to phlogiston; but of late an attempt has been made to prove that all the earths are metallic oxyds, and that they can actually be redu-

ced to the state of metals.

Baron had long ago suspected that alumina had somewhat of a metallic nature; and Bergman had been induced, by its great weight and feveral other appearances, to conjecture that barytes was a metallic oxyd: But the first chemist who ventured to hint that all earths might be metallic oxyds was Mr Lavoisier *. * Chemistry, About the year 1790, foon after the publication of Mr p. 217. Lavoisier's book, Mr Tondi and Professor Ruprecht, English both of Schemnitz, announced, that they had obtained from barytes, by the application of a strong heat, a metal of the colour of iron, and attracted by the magnet, which they called borbonium; from magnefia another, which they called austrum; a third from lime, also called auftrum; and a fourth from alumina, which they denominated apulum. Their method of proceeding was to apply a violent heat to the eartlis, which were furrounded with charcoal in a Hessian crucible, and covered with calcined bones in powder.

But their experiments were foon after repeated by Klaproth, Savorefi, and Tihauski; and these accurate chemists soon proved, that the pretended metals were all of them phosphurets of iron. The iron, by the violence of the heat, had been extracted from the crucible, and the phosphorus from the bones. The earths therefore must still continue a distinct class of bodies: and, as Klaproth has observed, their properties are so exceedingly different from those of metallic oxyds, that the supposition of their being composed of the same ingredients is contrary to every fact, and to every analogy with which

we are acquainted.

CHAP. V. Of CALORIC.

Nothing is more familiar to us than heat; to attempt to define it therefore would be unnecessary. When we say that a person feels heat, that a stone is hot, the

⁽y) This fubstance was contained in a mineral brought from Sidney Cove in New Holland. Wedgewood's analysis was published in 1790. Klaproth afterwards analysed it without finding the new earth which it had been supposed to contain; but doubts were entertained concerning the identity of the minerals examined by these two philosophers. These doubts have been removed by Mr Hatchet. (z) Mr Sage, however, pitched upon lime.

Caloric. expressions cause no difficulty; every one understands them perfectly: yet in each of these propositions the word heat has a diffined meaning. In the one, it fignihes the fensation of heat; in the other, the cause of that fensation. This ambiguity, though of little consequence in common life, leads unavoidably in philosophical discuffions to confusion and perplexity. It was to prevent this that the French chemists made choice of the word caloric, to fignify the cause of heat. When I put my hand on a hot stone, I experience a certain fensation, which I call the fensation of heat; the cause of this senfation is caloric

Whether

Concerning the nature of caloric, there are two opinions which have divided philosophers ever fince they a substance turned their attention to the subject. Some suppose that caloric, like gravity, is merely a property of matter, and that it confifts, some how or other, in a peculiar vibration of its particles; others, on the contrary, think that it is a distinct substance. Each of these opinions has been supported by the greatest philosophers; and the obscurity of the subject is such, that both sides have been able to produce exceedingly plaufible and forcible arguments. The recent discoveries, however, in this branch of chemistry, have rendered the latter opinion much more probable than the former. Indeed we do not see how it is possible to account for many of the phenomena of nature, unless caloric be considered as a fubstance, as we trust shall appear from the investigation into which we are about to enter. We mean, then, with the generality of modern chemists, to take it for granted, that caloric is a substance, without pretending

to be able to demonstrate the truth of our opinion, but merely because we consider it as infinitely more plaufible than the other. If the receiver of an air-pump, while it contains a thermometer, be suddenly exhausted of air, the thermometer finks feveral degrees, and then gradually rifes again to its former height. Now if heat be owing to vibration, how comes it that the small quantity of matter remaining in the receiver is first infufficient, and afterwards sufficient to maintain the temperature? Is it not more probable that part of the caloric was carried off with the air, and that it gradually returned through the glass, which it is capable of pervading, though with difficulty *. When air is let into * See Pia vading, though with difficulty ". When all is let fitte fur le an exhausted receiver, the thermometer, as Lambert first fee, ch. 1, observed, rises several degrees. Is not this owing to an additional quantity of caloric introduced by the air? The thermometer then finks flowly. Is not this because the superabundant caloric gradually pervades the glass and flies off? Taking it for granted then, that caloric is a substance, we proceed to examine its properties.

1. When bodies become hot, or, which is the same Calorices thing, when caloric enters into them, they expand in pands boevery direction; and this expansion is proportional to the dies. accumulation of caloric. The first and most obvious property of caloric then is the power of expanding bo-It does not, however, expand all substances equally, and we are still ignorant of the law which it follows. All that can be done therefore is to collect facts till this law be discovered. A number of these

may be feen in the following table:

. These doubts have been removed by Mr Hatcher,

From

(A) this mark ‡ implies, that, owing to some inaccuracy in making the experiments, the numbers to which it

is attached are not to be depended on. (B) The metal whose expansion is here given was an alloy composed of three parts of copper and one of tin. The figures in some of the preceding columns are to be understood in the same manner. Thus in the last column but two, the metal confifted of two parts of brass alloyed with one of zinc.

Caloric.

From this table, it appears that the gases are more expanded by caloric than fluids, and fluids more than folids; and that the expansion of all bodies hitherto ex-Exception. amined, mercury alone excepted, goes on in an increafing feries. To the expanding power of caloric there is one fingular exception: From 30° to 40° Fahrenheit, quater, instead of being expanded, suffers a remarkable contraction, as is evident from the following table of its bulk for every degree between 30° and 40°.

Bulk. 30° - - - 100074 31 - - - 100070 32 - - - 100066 33 - - - 100063 34 - - - 100060 35 - - - 100058 36 - - - 100056 37 - - - 100055 38 - - - 100054 39 - - - 100054 40 - - - 100054 *.

244 Thermometer.

The expansion of bodies by caloric has furnished us with an instrument for measuring the various degrees of it in different fubstances, we mean the thermometer; and as mercury is the only fluid which expands equably, it is obviously the only proper one for thermometers. The thermometer uniformly used in this article is that of Fahrenheit, except when some other is particularly mentioned.

245 No body

2. By means of the thermometer, we learn that there without ca-is no body which does not contain caloric, because there is none fo cold that it cannot be made colder: and cooling a body is nothing else but abstracting a part of the caloric which it contains.

Equilibrium of caloric.

3. Caloric cannot be confined in any body while those in its neighbourhood are colder, but continues to rush out till every thing is reduced to the same tempe-This does not proceed from the attraction of the colder bodies, but from the tendency of caloric to exist everywhere in an equal degree of tension: For when hot bodies are placed in the exhausted receiver of an air pump, as we learn from Mr Pictet+, or in the + Sur le Feu, an air-pump, as we chan, vi. Torricellian vacuum, as Count Rumford has shewn us ‡, the caloric leaves them in the fame manner, tho' more flowly, and they are equally reduced to the temperature of the furrounding bodies. This property has been called the equilibrium of caloric. The only way therefore to confine or accumulate this fubstance in a body, is to furround it with bodies which are hotter than itself.

4. The equilibrium of caloric feems evidently to prove

that its particles repel each other. This repulsion will Caloric, cause them when accumulated in any place to fly off in every direction, and to continue to separate till they are The parti. opposed by caloric in other bodies of the same relative cles of calo. density with themselves, which, by repelling them in its ric repel turn, compels them to continue where they are. The each other. caloric in bodies therefore is in what has been called by Mr Pictet a state of tension (c). Its particles are actuated by a force which would make them separate to an indefinite distance, were they not confined by the opposite force of the caloric which surrounds them. The equilibrium therefore depends on the balancing of two oppolite forces; the repulsion between the particles of caloric in the body, which tends to diminish the tempera. ture; and the repulsion between the caloric of the body and the furrounding caloric, which tends to raise the temperature. When the first force is greater than the fecond, as is the case when the temperature of a body is higher than that of the furrounding bodies, the caloric flies off, and the body becomes colder. When the last force is stronger than the first, as is the case when a body is colder than those which are around it, the particles of its caloric are obliged to approach nearer each other, new caloric enters to occupy the space which they had left, and the body becomes hotter. When the two forces are equal, the bodies are faid to be of the same temperature, and no change takes place *.

It is the action of these opposite forces which makes tet fur le the thermometer a measure of temperature. When ap- Feu, ch. i. plied to any body, it continues to rife or fall till the ealoric in it and in the body to which it is applied are of the same tension, and then it remains stationary. The thermometer therefore merely indicates that the temperature of the body to which it is applied is equal to its own. It is obvious that, in order to obtain the real temperature of bodies, the thermometer should be so fmall that the quantity of caloric, which enters or leaves

it, may not materially affect the refult.

This property of caloric feems to be the cause of the elasticity of the gases, in which, as we shall shew afterwards, it exists in great quantities. Perhaps it is the cause of elasticity in general; for we have no demonfrative evidence that the particles of elastic bodies repel each other (D), and we are certain that all of them contain caloric. Perhaps also it is owing to this repulfive property of caloric that the particles of no body actually touch each other; for the less caloric we leave in a body, the nearer its particles approach to one another. The expansion of bodies by calorie teems also to depend on the same property. The particles of caloric uniting with those of the body, endeavour to drag them along when they recede from each other. 'The expan-

(B) There was a curious fact concerning dilatation observed by Mr de Luc. A brass rod which he used as a thermometer became in funmer habitually longer; that is to fay, that after being for some time lengthened by heat, it did not contract by the application of cold to its old length, but continued fomewhat longer. In winter the contrary phenomenon took place. After being contracted for some time by cold, it did not return to its old length on the application of heat, but kept somewhat shorter. A leaden rod shewed these effects in a greater degree. Glass has not this quality. De Luc suspects that this property is inversely as the elasticity of bodies. Glass is persectly elastic, and lead is less elastic than brass .- Journ. de Phys. xviii. 369.

(c) The phrase was first used by Mr Volta.

(n) We acknowledge that feveral philosophers of the first rank, Æpinus for instance, and Boscovich, have supposed, that the particles of all bodies both attract and repel each other; but we cannot help thinking it rather improbable (if ithe possible) that two such opposite properties should exist together.

1 Phil. Trans. 1786, Part I.

fion of bodies therefore ought to be inversely as their cohesion, and directly as the tension of the caloric which they contain. This property of caloric feems likewise to afford an explanation of a very curious fact, which was first, we believe, mentioned by De Luc in his Treatise on the Modifications of the Atmosphere, and afterwards e- afcertained by Dr George Fordyce, that bodies become ht absolutely lighter by being heated. He took a glass globe three inches in diameter, with a fhort neck, and weighing 451 grains; poured into it 1700 grains of water from the New river, London, and then fealed it hermetically. The whole weighed 215011 grains at the temperature of 32°. It was put for twenty minutes into a freezing mixture of fnow and falt till fome of it was frozen; it was then, after being wiped first with a dry linen cloth, next with clean washed dry leather, immediately weighed, and found to be of the of a grain heavier than before. This was repeated exactly in the fame manner five different times. At each, more of the water was frozen and more weight gained. When the whole water was frozen, it was 3 ths of a grain heavier than it had been when fluid. A thermometer applied to the globe flood at 10°. When allowed to remain till the thermometer rose to 32°, it weighed 12ths of a grain more than it did at the same tempera. ture when fluid. We shall shew afterwards that ice contains less caloric than water of the same temperature with st. The balance used was nice enough to mark Too th part of a grain *. Morveau too found, much about the fame time, that water put into veffels hermetically fealed weighed more when frozen than when fuld |: and Mr Chaussier found, that two pounds of 783. Sulphuric acid were three grains heavier when frozen than after they had recovered their fluidity ‡. Now if the particles of caloric repel each other, bodies which contain it in great quantities must be somewhat repelled by each other. The more replete therefore that any body is with ealoric, the more it will be repelled by the earth, which always contains a great quantity; and this repulsion must in some degree counteract its gravitation. This explanation was first suggested, we believe, by

The same property explains another curious fact difnore covered by Mr Pictet of Geneva, that caloric moves more readily vertically upwards than downwards. He ards took a tube of tinplate, two inches in diameter and 44 in length, and inclosed in it a bar of copper four lines in diameter and 33 inches in length, which was placed and fixed exactly in its axis. This tube was exhaulted Ma. of air, by means of an air-pump, till the manometer * flood at the height of four lines. It was inclosed in an. other tube of pasteboard, except about two inches, exactly in the middle, to which place the fun's rays were directed for half an hour by means of a concave mirror. The ends of the copper bar were scooped out into concave hemispheres; and into each of these the bulb of a very fenfible thermometer was fixed. The tube was placed vertically. The highest thermometer, which we shall call A, rose to 95°, a hundred and one seconds before the lowest B. The thermometer B rose no high-

er than 95°; but the thermometer A reached 101,750. Caloric. To fee whether this difference was owing to the thermometers, the tube was inverted, and confequently the highest thermometer in the former experiment was lowest in this. The thermometer B now rose from 49° to 97,25° in 2810'; the thermometer A in 2763", or 47' fooner than B. It was evident from this refult, that the thermometer A was more sensible than the thermometer B by 47". If this be subtracted from 101", the former difference, it will leave 54", as the difference refulting from position. There experiments were repeated with only this difference, that round the ends of the bar and the bulbs of the thermometers (but without touching the bulbs) fome folds of oiled paper were wrapped to confine the caloric. The fuperior thermometer A rose from 500 to 106,250 in 34 minutes, which was 93" fooner than the interior B: it rose to 110,75°, the thermometer B only to 106,25°. The tube being reversed, the thermometer A, which was now lowest, rose from 46° to 115,25° in 40' 30", or forty seconds sooner than the thermometer B. This subtracted from 93", as formerly, leaves 53' for the difference of fituation. The superior thermometer mounted after the barning glass was removed 0,45°, remained stationary for 80", and after five minutes had only descended 0,450: the other did not ascend at all; in one minute it descended 0,225°, and in 6' 8" it descended 2,47°. In 22' 50" the inferior descended 63,725°, the superior 61,475° *. * Pietet From these experiments, it is obvious that the particles sur le Few, of calorie move fomewhat fafter, and in fomewhat great-chap. 2er quantity, upwards than downwards; owing, doubtless, to the repulsive power of the caloric in the earth. The small quantity of air that remained in the tube, may perhaps be supposed sufficient to account for the difference, without allowing any fuch tendency upwards in caloric. But it is evident from the experiments of the Florentine academicians on the same subject, with tubes full of air, that even when in great abundance, that fluid hardly affected the rifing of the superior thermometer: furely then its effect must be altogether imperceptible when fo little of it remained; and in the third and fourth experiments the oiled paper prevented any of the heated air from approaching the thermo-

5. If we take a bar of iron and a piece of stone of Condusting equal dimensions, and putting one end of each into the power of fire, apply either thermometers or our hands to the bodies: other, we shall find the extremity of the iron fensibly hot long be ore that of the stone. Caloric therefore does not pass through all bodies with the same celerity and ease. The power that bodies have to allow it a passage through them is called their condusting power; those that allow it to pass with facility, are called good condustors; those through which it passes with difficulty, are called bad condustors; and those which do not allow it to pass at all, non condustors.

It is probable that all folids conduct heat in some de- of wood gree, at least this is the case with every one at present and charknown. Wood and charcoal are exceeding bad conductors coal; of caloric (E). Count Rumford informs us, that a piece

(E) This fact merits the attention of chemists. It is obvious, that when metallic oxyds are furrounded with charcoal powder, their temperature cannot be raised near so high as it otherwise would be. It is not unlikely that some part of the difficulty which has been experienced in attempting to reduce and suffered metallic substances may have been owing to this cause.

Caloric. of green oak plank was employed to fir the melted metal of which cannons were founding at Munich, and it was often allowed to remain a confiderable time in the furnace; yet the caloric had penet ited to fo inconfi derable a depth, that at the difance of 10th of an inch below the furface, the wood did not feem to have been the least effected by it; the colour remained unchanged, and it did not appear to have lost even its moif-

* Rumford's ture *. E.J.ys, ii. 29. 253 Of glass;

254

Glass is also a very bad conductor; and this is the reason that it is so apt to crack on being heated or cooled suddenly; one part of it receiving or parting with its caloric before the rest, expands or contracts,

and destroys the cohesion.

Metals are the best conductors of caloric of all the Of metals; folids hitherto examined. The conducting powers of all, however, are not equal. Dr Ingenhousz procured cylinders of feveral metals exactly of the same fize, and having coated them with wax, he plunged their ends into hot water, and judged of the conducting power of each by the length of wax-coating melted. From these experiments he concluded, that the conducting powers of the metals which he examined were in the following

* Yourn de oider *: Phys. 1789, p. 68.

Silver. Gold, Copper, nearly equal, Tin, Platinum, Iron, much inferior to the others. Steel, Lead,

255 Of thones and foli's melting.

Next to metals stone seems to be the best conductors; but this property varies confiderably in different stones. Bricks are much worfe conductors than most stones. All folids capable of being melted become non conductors the moment they are heated to the melting point: the caloric enters them eafily enough, but it remains in

256 All fluids non conductors of caloric.

All fluids hitherto examined are non conductors of caloric. They can receive it indeed from other fubstances, and they can give it out to other substances; but one particle can neither receive it nor give it out to another particle. Before a fluid therefore can either be heated or cooled, every particle must go individually to the fubstance from which it receives or to which it gives out caloric. For this very important discovery the world is indebted to Count Rumford. Before the publication of his essays it had not even been suspected; so far from it, that fluids had been ranked among the best conductors of caloric.

How this was discowered.

In a fet of experiments on the communication of heat, he made use of thermometers of an uncommon fize. Having exposed one of these (the bulb of which was near four inches in diameter) filled with alcohol to as great a heat as it could support, he placed it in a window to cool where the fun happened to be shining. Some particles of dust had by accident been mixed with the alcohol: these being illuminated by the sun, became perfectly visible, and discovered that the whole liquid in the tube of the thermometer was in a most rapid motion, running fwiftly in opposite directions upwards and downwards at the fame time. The afcending current occupied the axis, the defcending current the fides of the

tube. When the fides of the tube were cooled by means of ice, the velocity of both currents was accelerated. It diminished as the liquid cooled; and when it had acquired the temperature of the room, the motion ceased altogether. This experiment was repeated with lintfeed oil, and the refult was precifely the same. These currents were evidently produced by the particles of the liquid going individually to the fides of the tube, and giving out their caloric. The moment they did fo, their specific gravity being increased, they fell to the bottom, and of course pushed up the warmer part of the fluid, which was thus forced to ascend along the axis of the tube. Having reached the top of the tube, the particles gave out part of their caloric, became specifically heavier, and tumbled in their turn to the bottom.

As these internal motions of fluids can only be difcovered by mixing with them bodies of the fame specific gravity with themselves, and as there is hardly any fubstance of the same specific gravity with water which is not foluble in it, Count Rumford had recourse to the following ingenious method of afcertaining whether that fluid also followed the same law. The specific gravity of water is increased considerably by dissolving any falt in it; he added, therefore, potass to water till its specific gravity was exactly equal to that of amber, a fubstance but very little heavier than pure water. A number of fmall pieces of amber were then mixed with this folution, and the whole put into a glass globe with a long neck, which, on being heated and exposed to cool, exhibited exactly the same phenomena with the other fluids. A change of temperature, amounting only to a very few degrees, was fufficient to fet the currents a-flowing; and a motion might at any time be produced by applying a hot or a cold body to any part of the vessel. When a bot body was applied, that part of the fluid nearest it ascended; but it descended on the application of a cold body.

If caloric pass through water only by the internal Proofs motion of its particles, as this experiment feems to the motion prove, it is evident that every thing which embarraffes power these motions mu't retard its transmission: and accord-water, ingly Count Rumford found this to be the case. He took a large lintfeed oil thermometer with a copper bulb and glass tube: the bulb was placed exactly in the centre of a brass cylinder, so that there was a void space between them all around 0,25175 of an inch thick. The thermometer was kept in its place by means of four wooden pins projecting from the fides and bottom of the cylinder, and by the tube of it passing through the cork stopper of the cylinder. This cylinder was filled with pure water, then held in melting fnow till the thermometer fell to 32°, and immediately plunged into a vessel of hoiling water. The thermometer role from 32° to 200° in 597". It is obvious that all the caloric which ferved to raife the thermometer must have made its way through the water in the cylinder. The experiment was repeated exactly in the same manner, but the water in the cylinder, which amounted to 2276 gr. had 192 gr. of ftarch boiled in it, which rendered it much less fluid. The thermometer now took 1109" to rife from 32° to 200°. The fame experiment was again repeated with the same quantity of pure water, having 192 gr. of eiderdown mixed with it, which would merely tend to embarrals the motion of the par-

ticles. A quantity of stewed apples were also in another experiment put into the cylinder. The following tables exhibit the result of all these experiments.

Time the Caloric was in passing into the Thermometer.

Tempera-	Through the Water and Starch	Thro' the Water and Eiderdown.	Through flewed Apples	Theough pure Water

Therm fell 80°, viz from 160° to 80°, in	468	460	520	277

Now, neither the flarch nor the eiderdown could produce any alteration in the water except impeding its internal motions; confequently whatever impedes these motions diminishes the conducting power of water. But this could not happen unless every indidual particle actually went from the cylinder to the thermometer.

Only one proof more was wanting to remove every doubt; and this proof also Count Rumford has given us. If water be a non-conductor, it is evident that no caloric can pass downwards when the heat is applied to the furface; for as the particles of water become specifically lighter by being heated, they cannot fink to the bottom. Accordingly Count Rumford found, that water might be made actually to boil near the top of a glass tube, while that at the bottom was not sensibly warmed. Owing to the law already mentioned, indeed, that water, after being cooled down to 40°, expands instead of contracting when its temperature is lowered, a mass of water may be raised to 40° by applying the heat to its upper surface; because water at 40° is heavier than at any degree below it, and will therefore fink to the bottom; but its temperature cannot be raifed any higher. This Count Rumford proved, by shewing that water of the temperature of 40°, placed above ice, will melt as much of it in the same time as water at any higher temperature whatever, even boiling hot.

Into a cylindrical glass jar 4,7 inches in diameter and 13,8 inches high, he put 43,87 cubic inches, or 1 lb.

11 toz. troy of water, and placing the jar in a freezing mixture composed of pounded ice and common fea falt, he froze the water into one con pact mass. The jar was then put into a mixture of pounded ice and pure water, reaching exactly to the top of the ice in it, and fuffered to remain there four hours, that the ice might come to the temperature of 32°; then boiling water was cautiously poured on it, and the jar still allowed to stand in the ice and water. He foon found that a confiderable quantity of ice was melted at the very beginning of the experiment, owing to the agitation into which the water was thrown by the act of pouring it into the vessel. To prevent this as much as possible, he covered the ice with a fmall quantity of ice cold water, upon which he placed a flat shallow dish of light wood 4 1 inches in diameter, and about one-fourth of an inch thick at the bottom. This vessel was perforated by several hundred very small holes. The hot water was poured into this dish through a long wooden tube, the bottom of which was stopped up, and the water made to iffue through small holes in the fide at the lower end. As this dish always floated on the furface of the water, and as the fluid peffing through it by a number of small holes was not projected with force, it is evident that a considerable part of these violent motions was prevented. The following is the refult of three experiments made in this manner.

Number of Experi- ments.	Time the hot Water was on the Ice.	Temperature of the het Water one inch below its furface. At the beginning. At the end		Quantity of Ice melted.	
ī	Minutes.	1920	1829	Grains. 580	
2	30	1900	165°	914	
3	180	1900	95°	3200	

From these experiments he determined the quantity of ice melted in the act of pouring the water into the jar, supposing equal quantities to be melted in equal times. It 3200 grains were melted in 180', subtracting 580, the quantity melted in 10', there remains 2620 gr: for the quantity melted in 170', in every ten of which 154 gr. must have been melted; for 170: 10: : 2620 : 154 nearly. Subtracting 154 from 580, the quantity melted in the first ten minutes, there remains 426 gr. for the quantity melted in pouring the water into the jar-From the fecond experiment it follows, by a fimilar calculation, that 159 gr. were melted every 10 minutes; which shows that the motions produced by pouring in the water had not ceased in 30 minutes. It will be nearer the truth, therefore, if we endeavour to discover the quantity melted every ten minutes by comparing the fecond and third experiments. By a fimilar calculation to the above, it comes out to be 152 gr. The following table exhibits the refults of feveral experiments, made exactly in the same manner, but with water at a much lower temperature.

Number

Temper. of the Water in the Jar one inch below its Time the Number Temper. Quantity of furface. Water reof Expeof the mained on Ice melted. riments. Before After Air. the Ice. 410 400 10 410 I 203 gr. 2 41 40 41 10 220 3 41 40 41 IO 237 228 4 40 41 IO 41 38 617 5 41 41 30 6 41 38 41 30 585

From these experiments it appears that the quantity of ice melted in 10' by water at the temperature of 410 was 222 gr. while boiling water melted only 152 gr. in the same time. To discover whether any of this was melted in the act of pouring in the water; from a mean of the two last experiments it appears, that 601 grains were melted in 30': if from this 222 grains (the mean of the four first) be deducted, there will remain 379 grains for the quantity melted in 20', consequently 1892 grains is what must have been melted in the ordinary course of the process; a quantity considerably above 152 grains. Therefore water at 41° melts more ice in the same time than boiling water. This Count Rumford accounts for by supposing, that in the hot water the descending current from the top of the vessel, and ascending one from the ice, meeting one another in that part of the vessel where the temperature is 40°, retard each others motions, and thus prevent the melting procefs from going on fo rapidly as when there is no defcending current. And he found accordingly, that when the cooling of the water above was retarded by wrapping up the jar in a warm covering, the ice melted fafter; and when the cooling above was accelerated, it melted flower. It is evident, that in the one case the velocity of the descending current was diminished, in the other accelerated.

Thus it has been completely proved, that water is a non-conductor of caloric. But is this the case also with other liquids?

When water was frozen in a glass jar by means of a freezing mixture, Count Rumford observed, that the ice first began to be formed at the sides, and gradually increased in thickness; and that the water on the axis of the veffel, which retained its fluidity longest, being compressed by the expansion of the ice, was forced upwards, and when completely frozen formed a pointed projection or nipple, which was fometimes half an inch higher than the rest of the ice. Upon ice frozen in this manner, he poured olive oil, previously cooled down to 32°, till it stood at the height of three inches above the The vessel was surrounded as high as the icc with a mixture of pounded ice and water. A folid cylinder of wrought iron, 13th inch in diameter and 12 inches long, provided with a hollow cylindrical sheath of thick paper, was heated to the temperature of 2100 in boiling water; and being fuddenly introduced into its sheath,

was suspended from the ceiling of the room, and very gradually let down into the oil, until the middle of the flat surface of the hot iron, which was directly above the point of conical projection of the ice, was distant from it only roths of an inch. The end of the sheath descended roth of an inch lower than the end of the hot metallic cylinder. Now it is evident, that if olive oil was a conductor, caloric would pass down through it from the iron and melt the ice. None of the ice, however, was melted; and when mercury was substituted for oil, the result was just the same ; consequently * Rumple it follows, that neither oil nor mercury is a conductor of the ice, however. We may conclude, therefore, with Count Rumball. We may conclude, therefore, with Count Rumball.

Sennebier observed some time ago, that air was a very Air; bad conductor of caloric, and that it refisted every change of temperature very much *. But it was refer. * 700%, ved for Count Rumford to prove, that it conducted it Phylips at all only by the internal motions of its particles, or that it was in fact a non-conductor, exactly in the fense that liquids are non-conductors *. This he established by * PM shewing, that whatever tended to obstruct or impede Trans. the internal motions of its particles, diminished its con-1792, ducting power. By mixing with a quantity of air 1 th Part l. of its bulk of eiderdown, he diminished its conducting power more than one half. The warmth of furs and feathers and filk depends on a very strong attraction between them and air, which is therefore confined in their interstices, and thus the caloric prevented from passing out of the body. A single metallic cover to a boiler in a short time grew so hot that it could not be touched, while another of exactly the fame form, but double, with a quantity of air confined in the middle, fearcely felt hot ‡. There can be no doubt that all the ‡ Rumford gases are also non-conductors; and Count Rumford has Esfay via proved the same thing of steam by the following expe-

riment, which we shall relate in his own words +: "A large globular bottle being provided, of very P. 61. thin and very transparent glass, with a narrow neck, And see and its bottom drawn inward to as to form a hollow hemisphere about 6 inches in diameter; this bottle, which was about 8 inches in diameter externally, being filled with cold water, was placed in a shallow dish, or rather plate, about 10 inches in diameter, with a flat bottom formed of very thin sheet brass, and raised upon a tripod, and which contained a fmall quantity (about 20ths of an inch in depth) of water; a spirit lamp being then placed under the middle of this plate, in a very few minutes the water in the plate began to boil, and the hollow formed by the bottom of the bottle was filled with clouds of steam, which, after circulating in it with furprifing rapidity 4 or 5 minutes, and after forcing out a good deal of air from under the bottle, began gradually to clear up. At the end of 8 or 10 minutes (when, as I supposed, the air remaining with the steam in the hollow cavity formed by the bottom of the bottle had acquired nearly the same temperature as that of the steam) these clouds totally disappeared; and though the water continued to boil with the utmost violence, the contents of this hollow cavity became so perfectly invisible, and so little appearance was there of steam, that, had it not been for the streams of water which were continually running down its fides, I should almost have been tempted to doubt whether any steam was actually gene-

Oil and mercury; "Upon lifting up for an inflant one fide of the bottle, and letting in a smaller quantity of cold air, the clouds instantly returned, and continued circulating several minutes with great rapidity, and then gradually disappeared as before. This experiment was repeated several times, and always with the same result; the steam always becoming visible when cold air was mixed with it, and afterwards recovering its transparency when, part of this air being expelled, that which re-

mained had acquired the temperature of the steam. " Finding that cold air introduced under the bottle caused the steam to be partially condensed, and clouds to be formed, I was defirous of feeing what visible effects would be produced by introducing a cold folid body under the bottle. I imagined that if steam was a conductor of heat, some part of the heat in the steam passing out of it into the cold body, clouds would of course be formed; but I thought if steam was a nonconductor of heat, that is to fay, if one particle of steam could not communicate any part of its heat to its neighbouring particles, in that case, as the cold body could only affect the particles of steam actually in contact with it, no cloud would appear; and the result of the experiment shewed that sleam is in fact a non-conductor of heat; for, notwithstanding the cold body used in this experiment was very large and very cold, being a folid lump of ice nearly as large as an hen's eog, placed in the middle of the hollow cavity under the bottle, upon a imall tripod or stand made of iron wire; yet as soon as the clouds, which were formed in confequence of the unavoidable introduction of cold air in lifting up the bottle to introduce the ice, were diffipated, which foon happened, the steam became so perfectly transparent and invisible, that not the smallest appearance of cloudiness was to be seen anywhere, not even about the ice, which, as it went on to melt, appeared as clear and as transparent as a piece of the finest rock crystal." Thus, then, it appears, that all elastic sluids are non-conductors as well as liquids.

6. If equal quantities of water and of mercury be placed at the same distance from a fire, the mercury will become hot much sooner than the water. After a sufficient interval, however, both of them acquire the ecific ca- far e temperature. Now caloric flows into all bodies ic of bo. while they continue of a lower temperature than those s, what around them, and it flows with equal rapidity into all bodies of the same conducting powers, as is the case with these two fluids: But if equal quantities of caloric were constantly flowing into the mercury and the water, and yet the water took a longer time to become hot than the mercury, it must require a greater quantity of caloric to raise water to a given temperature than it does to raise mercury. Bodies that require a greater quantity of caloric to raife them to a particular temperature than other bodies require, are said to have a greater capacity for caloric. That the capacity for caloric is different in different bodies, was first observed by Dr Black. Dr Irvine atterwards investigated the subject, and Dr Crawford published a great number of experiments on it in his Treatise on Heat. Protestor Wilcke of Stock-SUPPL. VOL. I. Part I.

holm also discovered the same property of bodies. He Caloric. called the quantity of caloric necessary to raise the temperature of substances a given number of degrees, their specific caloric; a term which we shall also employ, because the phrase capacity for caloric is liable to a great deal of ambiguity, and has introduced confusion into this subject (F). If two substances of unequal temperatures, as water at 1000 and alcohol at 500, be mixed together, the mixture will be of a temperature different both from that of the water and the alcohol, the water will become colder and the alcohol hotter: the water will give out caloric to the alcohol till both are reduced to the same temperature Now if it requires just as much caloric to raife alcohol a certain number of degrees as it does to raife water the same number, that is, if these two fluids are of the same specific caloric, it is evident that the temperature of the mixture will be just 75°; for as foon as the water has given out 25° of caloric, the alcohol has acquired 25, confequently both will be reduced to the same temperature, and will remain stationary; but if the specific caloric of the water be greater than that of the alcohol, the temperature of the mixture will be higher than 75°; for 25° of caloric in that case would raise alcohol more than 25°. If the specific caloric of water be so much greater than that of alcohol, that what raises water 200 will raise alcohol 300; then the temperature after mixture will be 800, because when the water has given out 200, the alcohol will have rifen 30°, and of course both will be of the same temperature. On the contrary, if the specific caloric of alcohol were greater than that of water, the temperature of the mixture would be under 750. If the same quantity of caloric that raised alcohol 200, raised water 30°, then the temperature of the mixture would be 70°. Thus the ratios of the specific caloric of bodies may be discovered by mixing them together at different temperatures.

The first set of experiments on this subject, in point Experiof time, were probably those of Mr Wilcke. They ments on were first published in the Stockholm Transactions for specific ca-1781, but had been made long before. The manner in Wilcke, which they were conducted is exceedingly ingenious, and they turnish us with the specific caloric of many of the metals. The metal on which the experiment was to be made was first weighed accurately (generally one pound was taken), and then being suspended by a thread, was plunged into a large veffel of tinplate, filled with boiling water, and kept there till it acquired a certain temperature, which was afcertained by a thermometer. Into another small box of tinplate exactly as much water at 32° was put as equalled the weight of the metal. Into this vessel the metal was plunged, and suspended in it so as not to touch its sides or bottom; and the degree of heat, the moment the metal and water were reduced to the same temperature, was marked by a very accurate thermometer. He then calculated what the temperature would have been if a quantity of water equal in weight to the metal, and of the same temperature with it, had been added to the ice-cold water instead of the metal.

LI

Let

⁽F) 'The term specific caloric has been used in a different sense by Seguin. He used it for the whole caloric which a body contains.

Caloric.

m another quantity at the temperature c, and let their common temperature after mixture be x; according to a rule demonstrated long ago by Richman, $w = \frac{MC + mc}{2}$ In the present case the quantities of water are equal, therefore M and m are each = 1; C, the temperature of the ice-cold water = 32: therefore $\frac{MC + mc}{M + m}$ = $\frac{32 + c}{2}$. Now c is the temperature of the metal: Therefore if 32 be added to the temperature of the metal, and the whole be divided by 2, the quotient will ex: press the temperature of the mixture, if an equal weight

of water with the metal, and of the same temperature with it, had been added to the ice-cold water instead of the metal.

He then calculated what the temperature of the mixture would have been, if, instead of the metal, a quantity. of water of the same temperature with it, and equal to the metal in bulk, had been added to the ice-cold water. As the weights of the ice-cold water and the metal are equal, their volumes are inverfely as their specific gravities. Therefore the volume of ice-cold water is to a quantity of hot water equal in volume to the metal, as the specific gravity of the metal to that of the water. Let M = volume of cold water, m = volumeof hot water, g = specific gravity of the metal, 1 = specific gravity of water; then m: M:: 1:g; hence. $m = \frac{M}{g} = (M \text{ being made} = 1) \frac{1}{g}$. Substituting this value of m in the formula, $\frac{MC + mc}{M + m} = x$, in

which M = 1 and C = 32, w will be $= \frac{32 g + c}{24 + c}$.

Therefore if the specific gravity of the metal be multiplied by 32, and the temperature of the metal be added, and the fum be divided by the specific gravity of the metal + 1, the quotient will express the temperature to which the ice-cold water would be raifed by adding to it a volume of water equal to that of the metal, and of the same temperature with it.

He then calculated how much water at the temperature of the metal it would take to raife the ice-cold water the same number of degrees which the metal had raised it. Let the temperature to which the metal had raifed the ice-cold water be = N, if in the formula

 $\frac{MC+mc}{M+m} = x, x \text{ be made} = N, M = 1, C = 32,$ $m \text{ will be} = \frac{N-32}{c-N}.$ Therefore if from the tempera-

ture to which the ice-cold water was raifed by the metal. 32 be subtracted, and if from the temperature of the metal be subtracted the temperature to which it raised

an lend of again. He also it for the subsit colorie

Let M be a quantity of water at the temperature C, the water, and the first remainder be divided by the last, the quotient will express the quantity of water of the temperature of the metal which would have raifed the ice-cold water the same number of degrees that the

Now $\frac{N-32}{c-N}$ expresses the specific caloric of the metal, that of water being = 1. For (neglecting the small difference occasioned by the difference of temperature) the weight and volume of the ice-cold water are to the weight and volume of the hot water as 1 to $\frac{N-3^2}{c-N}$, and the number of particles of water in each are in the same proportion. But the metal is equal in weight to the ice-cold water; it must therefore contain as many particles of matter; therefore the quantity of matter in the metal must be to that in the hot water as to $\frac{N-32}{c-N}$. But they give out the same quantity of

caloric; which, being divided equally among their particles, gives to each particle a quantity of caloric inverfely as the bulks of the metal and water; that is, the specific caloric of the water is to that of the metal

We shall now give a specimen or two of his experiments, and the calculations founded on them, as above described.

It is needless to add, that the last column marks the denominator of the specific caloric of the metal; the numerator being always 1, and the specific caloric of water being 1. Thus the specific caloric of gold is

In exactly the fame manner, and by taking 19,712. a mean of a number of experiments at different temperatures, did Mr Wilcke ascertain the specific caloric of a number of other bodies. He ascertained at the same time, that the specific caloric of a body did not vary with the temperature, but continued always the fame. This will appear evident from the experiments on gold and lead above exhibited.

Next, in point of time, and not inferior in ingenious contrivances to enfure accuracy, were the experiments of Dr Crawford, made by mixing together bodies of different temperatures. These were published in his Treatife on Heat.

Several experiments on the specific caloric of bodies were made also by Lavoisier and De la Place, which, from the well-known accuracy of these philosophers, cannot but be very valuable.

Their method was exceedingly simple and ingenious; it was first suggested by De la Place. An instrument was contrived, to which Lavoisier gave the name of calorimeter. It confifts of three circular veffels nearly inscribed into each other, so as to form three different appartments, one within the other. These three we shall call the interior, middle, and external cavities. The in-

terior cavity ffff (see section of the instrument sig. 4.), Caloric. into which the substances submitted to experiment are put, is composed of a grating or cage of iron wire, supported by several iron bars. Its opening or mouth LM is covered by the lid HG, which is composed of the fame materials. The middle cavity bbbb is filled with ice. This ice is supported by the grate m m, and under the grate is placed a fieve. The external cavity a a a a is also filled with ice. We have mentioned already, that no caloric can pass through ice. It can enter ice, indeed, but it remains in it, and is employed in melting it. The quantity of ice melted, then, is a meafure of the caloric which has entered into the ice. The exterior and middle cavities being filled with ice, all the water is allowed to drain away, and the temperature of the interior cavity to come down to 32°. Then the fubffance, the specific caloric of which is to be afcertained, is heated a certain number of degrees, suppose to 212°, and then put into the interior cavity inclosed in a thin veffel. As it cools, it melts the ice in the middle cavity. In proportion as it melts, the water runs through the grate and fieve, and falls through the conical funnel ccd and the tube xy into a veffel placed below to receive it. The external cavity is filled with ice, in order to prevent the external air from approaching the ice in the middle cavity and melting part of it. The water produced from it is carried off through the pipe ST. The external air ought never to be below 32°; nor above 41°. In the first case, the ice in the middle cavity might be cooled too low; in the last, a current of air flows through the machine and carries off some of the caloric. By putting various substances at the same temperature into this machine, and observing how much ice each of them melted in cooling down to 32°, it was easy to ascertain the specific caloric of each. Thus, if water, in cooling from 212 to 32, melted one pound of ice, and mercury ,029 of a pound; the specific caloric of water was one, and that of mercury ,029. This appears by far the fimplest method of making experiments on this subject; and must also be the most accurate, provided we can be certain that all the melted snow flows into the receiver. But from an experiment of Mr Wedgewood, one would be apt to conclude that this does not happen. He found that the melted ice, fo far from flowing out, actually froze again, and choaked up the passage.

A table of the specific caloric of various bodies was And Kirlikewise drawn up by Mr Kirwan, and published by Ma-wan. gellan in his Treatife on Heat.

From all these sources we have drawn up the follow-Result of ing table, which exhibits at one view the specific calo these experic of those bodies on which experiments have hitherto riments. been made.

We have added to it a column, expressing the specific caloric of equal bulks of the same bodies; which feems to be a more accurate way of confidering this fubject, and indeed the only way in which the phrase capacity for caloric is intelligible. This column was formed by multiplying the specific caloric of equal weights of the various substances into their respective specific gravities.

(H) The specific caloric of the substances marked * was ascertained by Dr Crawford, those marked † by Mr Kirwan, ‡ by Lavoisier and La Place, ** by Wilcke, || by Count Rumford. § Is the mean of Crawford, Kirwan, and Lavoisier; ¶ mean of Lavoisier and Kirwan; (c) mean of Crawford and Lavoisier; (d) mean of Wilcke and Crawford; (e) mean of Wilcke, Crawford, and Kirwan.

7. If a quantity of ice, at a low temperature, suppole at 2 , be suspended in a warm room, it will become gradually lefs cold, as may be difcovered by means of a thermometer, till it reaches the temperature of 32; but there it stops. The ice, however, dissolves flowly; and at the end of several hours, when it is all just melted, the thermometer still stands at 32%. After this it begins to rife, and foon reaches the temperature of the room. Here the ice continues for feveral hours colder than the air around it. Caloric must then be continually flowing into it; yet it does not become hotter: it is changed, however, into water Ice therefore is converted into water by a quantity of caloric uniting with it. This caloric has been called latent caloric, because its presence is not indicated by the thermometer. It might, perhaps with more propriety, as Professor Pictet observes +, be called caloric of fluidity; for there are other cases in which caloric exists in bodies without raifing their temperature. This very important discovery was made by Dr Black as early as 1757, and seems to have led the way to all the subsequent discoveries in this part of chemistry, which have almost completely changed the appearance of the science: for the discovery that caloric may exist in bodies while the thermometer cannot indicate its presence, is one of the strongest links in the chain of facts by which the nature of combustion was afcertained.

The caloric which unites with ice, and renders it fluid, appears again during the act of freezing. If a quantity of water be carried into a room where the temperature is below the freezing point, suppose at 200, it cools gradually down to 320; but it becomes no colder till it is all frozen, which takes up some time. The moment it is all converted into ice, it begins again to cool, and foon reaches the temperature of the room. In this case, the water is surrounded by a colder atmosphere; it must therefore be giving out caloric constantly; yet it does not become colder till it is all frozen, that is to fay, till it has lost all its ca-

loric of fluidity.

Dr Black proved, by a very accurate experiment, that the quantity of caloric of fluidity is sufficient to

raise the same quantity of water 140°.

All folids become fluid by absorbing a quantity of caloric. Landriani proved, that this is the case with fulphur, alum, nitre, and several of the metals 1; and it has been found to be the case with every substance hitherto examined. Fluidity, therefore, is owing to a union between the folid and a certain quantity of ca-

The late Dr Irvine of Glasgow advanced a theory on this subject different from that of Dr Black. The specific caloric of water being greater than that of ice, it requires a greater quantity of caloric to raise it to a given temperature than it does to raise ice. The caloric does not 'therefore become latent; it only feems to do so from the greater specific caloric of water. This

theory was zealously adopted by Dr Crawford. Dr Caloric. Black observed very juttly, that it did not account for the production of fluidity at all. The specific caloric of water is indeed greater than that of ice; but how is the ice converted into water? This is an objection which the advocates for Dr Irvine's, or Dr Crawford's, theory (as it has been improperly called) will not eafily answer. Let us now examine whether this theory accounts for the apparent lofs of caloric. It follows from Mr Kirwan's experiments, that the specific caloric of water is to that of ice as 10 to 9 (1). Dr Black proved, that as much caloric entered the ice as would have railed it, had it been water, 140°. Let us suppose that it would only have raised the ice 140°; in that case the melted ice ought to have been of the temperature of 158°, for 10:9::140:126; but it was only 32°: Therefore 126° of caloric have disappeared, and cannot be accounted for by the change of tpecific caloric. Nor can the accuracy of Dr Black's experiment be suspected: it has been repeated in every part of the world, and varied in every p slible way. We cannot doubt, therefore, that caloric unites with substances, and causes them to become fluid, or that there is in fact a caloric of fluidity different from specific

Water also is converted into feam by uniting with Caloric of caloric. Dr Black put an iron veffel, containing four evaporation ounces of water at the temperature of 53°, upon a castiron table which was red hot. The water rose to the boiling point in three minutes; but it did not afterwards become any hotter. It evaporated, however, in-18 minutes; and the fleam was precifely at the temperature of 2129. During the first three minutes, it received 159° of caloric, and as much must have been entering it during every three minutes while the evaporation continued, as the temperature was always much lower than that of the table. This caloric, instead of railing the temperature of the water, was employed in converting it into steam. There is also, therefore, a quantity of latent caloric in steam. It might, as Mr Pictet observes, be called, with propriety, caloric of evaporation. This caloric appears again if the steam be condensed. If it be made to pass, for instance, through a pipe furrounded with cold water, it is condensed in the pipe, and drops out from it in the form of water. The caloric of the fleam enters into the water around the pipe, and the quantity of it in degrees may be difcovered by the number of degrees which it raifes that water. By an experiment of this kind, it was proved, that the caloric of evaporation would be sufficient to heat water red hot, were it employed only in raising its temperature, instead of converting it into steam. It is therefore at least equal to 800°. Mr Watt shewed afterwards that it was 9200.

Even spontaneous evaporation, as Dr Black first obferved, is owing to the fame cause: and this explains why bodies cool when water is evaporated from their

(1) We do not know how this was afcertained: Not by mixing water and ice furely; because that would be taking for granted the thing to be proved; because it would give a very different result; and what is still worse, the specific caloric in that case would differ according to the temperature and the quantity of water. To give an instance: Mr Gadolin concludes, from 180 experiments made by mixing hot water and ice, that the specific. caloric of ice is to that of water only as 1 to 2 *; and had he varied the quantities and the temperatures, he might have obtained feveral other ratios.

Real zero,

what.

Caloric, surface; a fact which has been long known, and which has been employed in warm countries to diminish the temperature of liquids, and even to convert them into ice (k). That water is evaporated by uniting with ca-Joric, and not by folution in air, has been proved very completely by De Luc in his Treatife on Meteorology.

The evaporation of alcohol, ether, and every other fubstance on which experiments have been made, has been found owing to the fame cause. Bodies, therefore, are converted into vapour by uniting with caloric.

8. If caloric, as has been shewn, exists in bodies at the lowest temperature which we are able to procuse, and if it exists in them while the thermometer cannot discover its presence-is there any method of ascertaining its absolute quantity in bodies? At what degree would a thermometer stand (supposing the thermomeit is applied totally deprived of caloric? or what degree of the thermometer corresponds to the real zero?

The first person (as far as we know), at least fince

men began to think accurately on the subject, who con. Color ceived the possibility of determining this question, was Dr Irvine of Glasgow. He invented a theorem, in or 177 der to ascertain the real zero, which has, we know not theore for what reason, been ascribed by several writers to Mrd sover Kirwan. He took it for granted (and the fact is proved by all the experiments hitherto made) that the specific caloric of bodies continued the same in every degree of temperature, as long as they remained in the fame state, that is to fay, as long as they continued either folid or fluid or in a flate of vapour; but that the specific caloric of the same body while solid was less than while fluid, and less while fluid than while in a state of vapour. He took it for granted, too, that the 140 degrees of caloric which entered ice during its folution without raising its temperature, entered merely ter capable of measuring so low) were the body to which in consequence of the increased specific caloric of the water, and that they were exactly proportional to this increased specific caloric. He took it for granted, likewife, that the specific caloric of bodies was proportional

(K) Galen informs us, that the ancient Egyptians were accustomed to put water previously boiled into earthen jars, and expose them all night on the upper part of their houses to the air. Before sunrise these vessels were put into the ground, moistened on the outside with water, and then surrounded with fresh plants; by which means the water was preserved cool during the whole day. Comment. in lib. vi. Hippoc. de morbis vulgar. 4. 10. p. 396.

By a fimilar process, water, in the East Indies, is converted into ice.

The following fingular, passage, which has been pointed out to us by the ingenious Dr Barclay, lecturer on anatomy in Edinburgh, furnishes a striking proof that the ancients were led, by a very different method of reasoning, to deduce, from their philosophical theory of the four elements, conclusions concerning the nature of

heat not very different from those of the moderns.

"Sic enim res sé habet, ut omnia, quæ alantur et quæ crescant, contineant in sé vim caloris; fine qua neque ali possent nec crescere. Nam onne, quod est calidum et igneum, cietur et agitur motu suo : quod autem alitur et crescit, motu quodam utitur certo et æquabili ; qui quandiu remanet in nobis, tamdiu sensus et vita remanet : refrigerato autem et extincto calore, occidimus ipsi et exslinguimur. Quod quidem Cleanthes his etiam argumentis docet, quanta vis insit caloris in omni corpore : negat enim ullum esse cibum tam gravem, quin is nocte et die concoquatur; cujus etiam in reliquiis inest calor his quas natura respuerit. Jam vero venæ et arteriæ micare non desinunt, quasi quodam igneo motu; animadversumque sæpe est, cum cor animantis alicujus evolsum ita mobiliter palpitaret, ut imitaretur igneam celeritatem. Omne igitur quod vivit, five animal five terra editum, id vivit propter inclusum in eo calorem. Ex quo intellegi debet, eam caloris naturam, vim habere in se vitalem per omnem mundum pertinentem. Atque id faciliùs cernemus, toto genere hoc igneo, quod tranat omnia, subtiliùs explicato. Omnes igitur partes mundi (tangam autem maxumas) calore fultæ fustinentur. Quod primum in terrena natura perspici potest. Nam et lapidum conslictu atque tritu elici ignem videmus; et recenti fossione

-terram fumare calentem;

atque etiam ex puteis jugibus aquam calidam trahi, et id maxume sieri temporibus hibernis, quòd magna vis caloris, terræ contineatur cavernis; eaque hieme sit densior; ob eamque caussam, calorem insitum in terris contineat arctiùs.

" Longa est oratio, multæque rationes, quibus doceri possit, omnia, quæ terra concipiat, semina, quæque ipsa ex fe generata stirpibus infixa contineat, ea temperatione caloris et oriri et augescere. Atque aquæ etiam admixtum esse calorem, primum ipse liquor, tum aquæ declarat essuño: quæ neque conglaciaret frigoribus, neque nive pruinaque concresceret, nisi eadem se admixto calore liquefacta et dilapsa diffunderet. Itaque et aquilonibus reliquisque frigoribus durescit humor: et idem vicissim mollitur tepefactus et tabescit calore. Atque etiam maria agitata ventis ita tepescunt, ut intellegi facile possit, in tantis illis humoribus esse inclusum calorem. Nec enim ille externus et adventicius habendus est tepor, sed ex intimis maris partibus agitatione excitatus: quod nostris quoque corporibus contingit, cum motu atque exercitatione recalescunt. Ipse verò aer, qui natura est maxume frigidus, minime est expers caloris. Ille verò et multo quidem calore admixtus est: ipse enim oritur ex respiratione aquasum: earum enim quasi vapor quidam aër habendus est. Is autem existit motn ejus caloris, qui aquis continetur. Quam similitudinem cernere possumus in his aquis, quæ effervescunt subditis ignibus. Jam verò reliqua quarta pars mundi, ea et ilpa tota natura fervida est, et ceteris naturis omnibus falutarem inpertit et vitalem calorem. Ex quo concluditur, cum omnes mundi partes sustineantur calore, mundum etiam ipsum simili parique natura in tanta diuturnitate servari: eoque magis, quod intellegi debet, calidum illud atque igneum ita in omni fusum esse natura, ut in co insit procreandi vis et caussa gignendi, à quo et animantia omnia, et ea quorum sirpes terra continentur, et nasci sit necesse et augescere. Cicero de natura Deorum, lib. ii. c. 9, et 10.

to their absolute caloric, or to all the caloric which existed in each.

On these data he reasoned in the following manner: Let A be a body in a flate of fluidity; B the same body in a state of solidity. If the specific caloric of A and of B be known, and if it be known how many degrees the caloric, disengaged during the change of B into A, would raife the temperature of A, it may be found by an easy process how many degrees all the caloric contained in B would raise the temperature of A; and the fum of these two numbers will represent in degrees the whole quantity of caloric in A: for the quantity of caloric in A must be just equal to the caloric in B, together with what entered into it in paffing from the state of B to that of A. Let the specific caloric of A be 6, that of B 1; and let the quantity of caloric difengaged during the change of A into B be sufficient to raile the temperature of A 500°. If the specific caloric be proportional to the absolute caloric, it must contain exactly 6 times as much caloric as B. The 500° which entered into A when it changed its state, must be just 5 times as great as all the caloric of B; because when added to the caloric of B, it formed the caloric in A, which is just 6 times as great as the caloric in B. Therefore to discover the caloric in B, we have only to divide 500 by 5, or, which is the fame thing, to flate this proportion 6-1:500::1:100. The caloric in B, therefore, in this case is just as much as would raise the temperature of A 100°. Therefore, if to 100°, the caloric of B, be added 5000, = caloric difengaged in the passage of A to B, this will give 6000, = to all the caloric in A. Therefore, in all cases, the difference between the numbers expressing the specific caloric of the

quantity of caloric in the fluid. Dr Crawford embraced this theorem; and concluded, from a number of experiments made on purpole to afcertain the fact, that the real zero was 1268° below o,

solid and fluid, is to the number expressing the specific

caloric of the folid, as the quantity of caloric difengaged during the passage of the sluid into a solid is to the

or 13000 below the freezing point.

This subject deserves to be considered with attention. If this theorem in fact furnishes us with the real zero, it is one of the most important discoveries which has ever been made in chemistry; but if it proceeds on erroneous principles, it will only involve us in endless mazes of error and abfurdity.

In the first place, if the real zero has any meaning at all, it must fignify the degree to which the thermometer (supposing it could be used) would fink on being applied to a body which contained no heat. It must therefore be a fixed point; and were the theorem which we are examining well founded, experiments upon every different substance, if conducted with accuracy, would lead to the same result. Let us see whether this be the cafe.

From Dr Crawford's experiments, it follows, as we have feen, that the real zero is 1268° below o.

Mr Kirwan, from comparing the specific caloric of water and ice, fixed the real zero at 1048° below 0.

From the experiments of Lavoisier and La Place on a mixture of water and quicklime, in the proportion of 9 to 16, it follows, that the real zero is 27360 below 0.

From their experiments on a mixture of 4 parts of fulphuric acid and 3 parts of water, it follows, that the real zero is 5803,4° below 0.

Their experiments on a mixture of 4 parts of sui- Caloric, phuric acid and 5 of water, place it at 2073,3° below o. Their experiments on 9 parts of nitric acid and 1 of

lime, place it at _____, 1889 below 32° *.

* See Se-

These results differ from one another so enormously, de Chim. viz. and the last of them, which makes the real zero a negative quantity, is so absurd, that they are alone sufficient to convince us that the data on which they are founded are not true. Should it be faid that their difference is not owing to any defect in the theorem, but to inaccuracies in making the experiments-we answer, that the theorem itself is founded on similar experiments; and if experiments of this nature, even in the hands of the most accurate chemists, cannot be freed from such enormous errors, how can we depend on any confequences deduced from them? and where, then, is our evidence for the truth of the thcorem?

But, farther, there is no proof whatever that the specific caloric of bodies is proportional to their absolute caloric. The specific caloric of iron is greater than that of water, or even azotic gas; yet furely it is very improbable that iron contains more absolute caloric than

either of thefe fubstances.

If the specific caloric of bodies has any meaning at all, it can only be, that the same quantity of calorie raises the temperature of one body a greater number of degrees than it does another. When we fay that the fpecific caloric of A is = 6, and that of B = 1, what do we mean, unless that the quantity of caloric which raises B 6° raises A only 1°, or that what raises B 60° or 600°, railes A only 10° or 100°? When we fay that the specific caloric of water is 10, and that of ice 9, do we not mean, that the quantity of caloric which raises the ice 10° or 1003, raises water only 9° or 900? Yet during the change of ice into water, 1400 of caloric enter it without raifing its temperature; a quantity greater than what can be accounted for by the difference of specific calorie by 126°. The quantity that disappears, therefore, is not proportional to the difference of specific caloric; and therefore any theory which depends on that supposition cannot be well founded. When water is converted into steam, 800° of caloric disappear; yet the specific caloric of steam is to that of water, according to Dr Crawford's own experiments, only as 155 to 100: so that no less than 2830 disappear, which cannot be accounted for according to this theory.

Dr Irvine's theorem, therefore, is infufficient for af- And found certaining the real zero; and hitherto no method has infufficient. been discovered which can folve this problem.

9. If there be no body without caloric; if it exists in Caloric exdifferent quantities in different bodies, even when their ifts in botemperatures are the same; and while the thermometer dies cannot indicate its presence-in what state does it exist in them? We cannot furely suppose that it is contained by them just as water is contained by a vessel of wood or metal, or that they are filled with it in the same manner that a hollow globe of tin-plate perforated with holes is filled with water when it is plunged into a quantity of that liquid; or that bodies are filled with caloric merely because they are immersed in an ocean of caloric. Were that the cafe, the specific and absolute caloric of bodies would always be proportional; and they would of necessity be inversely as the specific gravity of the respective bodies; because the less the specia fic gravity, the more room would be left for the par-

tion.

Caloric. ticles of calorie. But this is by no means the cafe: the specific gravity of iron, for instance, is greater than that of tin, yet the specific caloric of iron is more than double that of tin: the specific gravity of oxygen gas is greater than that of common air, yet the specific caloric of the first of these substances is more than three times as great as that of the other. There must be fomething, therefore, in bodies themselves quite different from, and unconnected with the vacuities between their particles, which disposes some to admit more calorie than others. And what can that be but a disposition in different bodies to unite with a greater or a fmaller quantity of caloric, and to retain it with more or less firmuels according to their affinity for it? Dr Black pointed out, long ago, by discovering latent heat, that caloric unites with bodies; and this feems to be the only real key for unfolding the actions of this extraordinary substance. If caloric be matter, can it be destitute of that property which all other matter pos-In a state of session, we mean attraction? And if it possesses attraction, must it not combine with those bodies that attract it just as other bodies combine with each other? Must there not be formed a chemical union between caloric and other fubstances, which can only be broken by chemical means, by prefenting a third body which has a greater affinity either for the caloric or the body to which it is united, than they have for each other?

That it unites chemically with some bodies, at least, be the case cannot be doubted; as we have shewn already, that whenever a folid is converted into a liquid, a quantity of cain liquids, loric enters, and remains in it; and that both the folid and the caloric lose their characteristic properties. This is precisely what takes place in every chemical union. All liquids, therefore, confift of folids combined with caloric. We have feen, too, that liquids are converted into vapours by the very fame process. There are therefore, at least, two very large classes of bodies liquids and vapours, in which we are certain that caloric exists in a

state of chemical combination.

And gafes;

There is another class of bodies which refembles vapours in almost all their properties: these are the gases. Like them, they are invisible and elastic, and capable of indefinite expansion. Is it not probable, then, that the gases also, as well as the vapours, owe their properties to calorie? that they also confist of their respective bases combined with that subtile substance? This proof Lavoisier. By adding two tubes to the calorimeter formerly described, he contrived to make known quantities of air to pass through the interior cavity, and to support combustion. He found, that when a pound of oxygen gas was made to combine in this manner with phosphorus, as much caloric was disengaged as * Lawisser, melted 871 pounds of ice *. Now every pound of ice p. i. ch. 9. absorbs as much caloric in the act of melting as is sufficient to raise a pound of water 140°. Therefore the whole caloric disengaged was sufficient to raise a pound of water 12250°. All this could not have come from the phosphorus, because it had been converted into a liquid, and must therefore have absorbed instead of parted with caloric, and because the quantity of caloric disengaged in all cases of combustion is proportional, not to the combustible, but to the oxygen absorbed. Oxygen gas, then, is composed of oxygen and caloric: and if this be the cafe with one gas, why not with all?

We may conclude, therefore, that the gases, as well can as liquids and vapours, owe their form to the caloric which they contain. The only difference between them and vapours is, that the latter return to their liquid state by the mere action of cold; whereas most of the gases resist the lowest temperature which it has been possible to apply. It was natural to expect, that if caloric combined chemically with bodies, its affinity would be different for different substances, and that its affinity for some bodies would be so great that it would not leave them to combine with any other. It was natural to expece this, because it is the case with every other substance. with which we are acquainted. The difference, then, between the gases and vapours is not surprising. The affinity of the former for caloric is not only much greater than that of the latter, but much greater than that of any other substances.

'It is owing to this strong affinity between oxygen, And b hydrogen, and azot and caloric, that they cannot be the or obtained except in a gaseous form: and we shall describe there several other substances afterwards exactly in the same outline circumstances. Had we any substance possessed of a greater affinity for caloric than they have, we should be able, by prefenting it, to deprive them of their gaseous form. Doubtless there is a difference in the affinity between these bodies themselves and caloric; but as all of them are already faturated, this difference cannot be discovered. If we could obtain them uncombined with caloric, that is to fay, in a concrete state, it would be easy to ascertain this point. Suppose, for instance, that hydrogen had the strongest affinity for caloric, and that we possessed it in a concrete state-it would be easy, by prefenting it to the other gases, to deprive their bases of the caloric with which they are united, and thus to obtain them also uncombined with any other substance.

But though we are acquainted with no substance that Why a has a greater affinity for caloric than the bases of there pre gales, there are many substances which have a greater during affinity for these bases than caloric has. When any combin fuch subtance is presented, the base combines with it, and the caloric is left at liberty. Thus, when phosphorus is presented to oxygen gas, the phosphorus and oxygen unite together, and the caloric flies off. We are now, therefore, able to answer one of the questions proposed at the end of the second chapter, Whence comes the caloric which appears during combustion? It is febability has been reduced to certainty by an experiment | parated from the oxygen, which leaves it in order to enter into a new combination.

The caloric alfo, which fometimes appears when two Anddo bodies combine together, is fet at liberty exactly in the many fame manner. When fulphuric acid and water, for in-binated stance, are mixed together, a very considerable heat is produced; a good deal of caloric, therefore, becomes fensible. In this case, the water combines with the acid, and at the same time lets go the caloric with which it was formerly combined, and becomes denfer. In the same manner, to give another instance, when water is poured upon quicklime, a very great quantity of caloric becomes manifest. The water in this case combines with the quicklime, and affumes a concrete form, and of course lets go the caloric with which it was previously united.

10. It is no uncommon thing in nature to observe why two bodies, after combining together, manifesting atain m much stronger affinity for a third body than either of tures ! them duce a

pric. them had while feparate. Thus, filver has no perceptible affinity for fulphuric acid, neither has oxygen; but unite them together, and they combine with that acid very readily. A great many instances of the same kind might be produced. Were there substances, then, which, after combining together, have a greater affinity for caloric than any of them had while separate, this ought not to furprise us, because the same phenomenon is often observed in other bodies. Now this is actually the case with regard to caloric. Mix together, for instance, common falt and frow, the mixture instantly becomes liquid, and fo cold, that it finks the thermometer down to zero. In this case, the snow and salt united have a much stronger affinity for caloric than either of them had while separate; they attract it therefore from

other bodies with which they happen to be in contact, till they have obtained a dose sufficient for their saturation; and this faturation they manifest by becoming liquid. It is for this reason that all salts produce cold during their folution in water, when the freezing point of the folution

formed is below that of water. All fuch folutions have a firong affinity for caloric; they therefore attract it till they are saturated, which appears by their becoming fluid. A number of experiments have been lately made in order to procuse artificial cold by means of fuch combinations. The most complete set of experiments of that nature with which we are acquainted, is those of Mr Walker, published in the Philosophical Transactions for 1795. We shall present the result of his experiments in the following table:

TABLE of Freezing Mixtures.

1		
Mixtures.		Thermometer finks.
Muriat of ammonia Nitre - Water -	5 parts. 5	From 50° to 10°.
Muriat of ammonia Nitre Sulphat of foda Water	5 5 8 16	From 50 to 4.
Nitrat of ammonia Water	1 I	From 50 to 4.
Nitrat of ammonia Carbonat of foda Water -		From 50 to 7.
Sulphat of foda Diluted nitric acid	3 2	From 50 to 3.
Sulphat of foda Muriat of ammonia Nitre Diluted nitric acid	6 4 2 4	From 50 to 10.
Sulphat of foda Nitrat of ammonia Diluted nitric acid	6 5 4	From 50 to 14.
Phosphat of foda Diluted nitric acid	9	From 50 to 12.

SUPPL. VOL. I. Part I.

Mixtures.	Thermometer finks.	
Nitrat of ammonia	9 parts. 6 4	From 50° to 21°.
Sulphat of foda Muriatic acid	8	F'rom 50 to 0.
Sulphat of foda Diluted fulphuric acid	5 4	From 50 to 3.
Snow Common falt	I	From 32 to O.
Snow or pounded ice Common falt	2 I	From 0 to -5.
Snow or pounded ice Common falt Muriat of ammonia and nitre	5 5	From -5 to -18.
Snow or pounded ice I Common falt Nitrat of ammonia	5 5	From —18 to —25.
Snow and diluted nitric	acid	From 0 to -46.
Snow Diluted fulphuric acid Diluted nitric acid	2 I I	From — 10 to — 56.
Snow - Diluted fulphuric acid	I	From 20 to -60.

In order to produce these effects, the salts employed must be fresh crystallized, and newly reduced to a very fine powder. The vessels in which the freezing mixture is made should be very thin, and just large enough to hold it, and the materials should be mixed together as quickly as possible. The materials to be employed in order to produce great cold ought to be first reduced to the temperature marked in the table, by placing them in some of the other freezing mixtures; and then they are to be mixed together in a fimilar freezing mixture. If, for instance, we wish to produce a cold = -46, the fnow and diluted nitric acid ought to be cooled down to o, by putting the vessel which contains each of them into the 12th freezing mixture in the above table, before they are mixed together. If a flill greater cold is required, the materials to produce it are to be brought to the proper temperature by being previously placed in the second freezing mixture. This process is to be continued till the required degree of cold has been procured t.

11. From the facts already known, we may conclude, Phil. Tranf. that the particles of caloric have two properties, that 1795. of repelling each other, and of attracting and being at-Substances tracted by other substances. As there is no body in which connature which does not contain caloric, we may fafely tain most conclude, that there is no body in nature which has not caloric. an affinity for it. When it unites with bodies, though the repulsion of its particles may be overcome by their attraction for the particles of the body, and by the at-

Walker,

Mm traction Caloric. traction of these particles for each other-we cannot suppose it annihilated: It must therefore be the more powerful the greater the quantity of caloric combined in any body is. Probably, then, there is most caloric combined with gases, less with fluids, and least with solids. It does not follow, however, from this that the quantity of caloric combined with any body is proportional to the distance between its particles, because that may depend on other causes. Thus, though hydrogen gas is much rarer than oxygen gas, it does not follow that hydrogen is combined with more caloric than oxygen, because the rarity may be owing to the smaller cohesive force of the particles of hydrogen allowing a smaller quantity of caloric to produce a greater

bodies,

If caloric unites only chemically with bodies, there be a ided in-ought to be a certain point of faturation between it and definitely to the substances with which it combines, because this takes place in all other chemical combinations. Oxygen gas, for instance, consists of a certain quantity of oxygen united with caloric. Now if this gas be a chemical compound, the two ingredients ought to faturate each other in such a manner, that no more of either could be admitted. But it cannot be denied, that more caloric can still be added to oxygen gas, for its temperature may be raifed at pleasure as high as we think proper. This, at first fight, seems to be an insuperable objection to the theory that caloric only combines chemically with bodies. It ought to be remembered, however, that caloric is not fingular in this respect. There are other bodies in nature, and bodies too which certainly combine with other substances only by affinity, which exhibit the very same phenomenon. Water is capable of combining with fulphuric acid and many other falts almost in any proportion, at least no limits have hitherto been observed. Oxygen, too, combines with almost every body in various proportions: We have feen, that with almost every metal it forms at least two different oxyds. Why then may not caloric be capable of uniting in the same manner? Allowing, therefore, that it were impossible to explain why bodies are capable of combining with caloric after faturation, this could be no objection to the theory that it only unites chemically with bodies, because the same phenomenon is exhibited by other bodies which it cannot be doubted combine only by means of affinity.

285 And why.

The manner in which thefe other combinations are formed has been already hinted, and shall be considered more fully afterwards; at prefent we shall only attempt to explain the action of caloric. Let us suppose, then, that caloric is prefented to oxygen; that they combine together in a certain proportion, and faturate each other. The product of this combination is oxygen gas; a substance possessed of properties very different from those of caloric or oxygen in a concrete state; it is incapable of being decomposed by any merely mechanical method, and exhibits all the appearances of a simple substance. Let us therefore confider this compound for a moment as a fimple substance. May it not still have an affinity for caloric? and will it not, in that case, unite with it? Oxygen gas and caloric have an affinity for each other; accordingly, when prefented to one another they combine in a certain proportion, and form a new compound, differing from oxygen gas, properly fo called, in elasticity, specific gravity, and feveral other particulars. The affinity, however, between oxygen gas and caloric is much

feebler than that between oxygen and caloric; for the Caloric, new compound is eafily broken, and the caloric absorbed ' by many other fubstances. We can even conceive this new compound still to have an affinity for caloric, to unite with it, and to form another compound, the affinity between the ingredients of which is still feebler. And in this manner may the indefinite increase of temperature be accounted for.

Subflances may be conceived to be conductors of ca-Caufe of loric inversely as their affinity for it. Good conductors the diffemay have very little affinity for caloric; and for that rent conreason it may be easily forced through them by the re-ducling pulsion of its own particles. But those substances powers of different which have a great affinity for caloric, combine with it bodies, the moment it is presented to them; and consequently it cannot pass through them. Thus, when it is prefented to ice, the affinity between the two substances is fo great, that the caloric unites with the very first particles of ice which it meets with. The particles behind these cannot receive any caloric, except by attracting it from the particles with which it has already combined. But the affinity of one particle of ice for caloric cannot be greater than that of another particle of ice: and the union of two bodies cannot be broken by a force not greater than that which unites them; therefore the caloric cannot pass from one particle to another. Consequently, supposing all the particles to keep their places, no new caloric could enter. Just as when a piece of marble is put into fulphuric acid, the crust of fulphat of lime which very foon covers it prevents the acid from getting to the particles of marble within. But as foon as a particle of ice unites with caloric, water, the new compound, leaves its station, and allows the caloric a paffage to the other particles.

In the fame manner, when caloric is prefented to water, it combines with the outermost stratum of particles, and forms with them a compound which cannot be decomposed by the other particles of the water, because their affinity for caloric is no greater than that of the particles already united with it. No more caloric, then, could gain admission, were it not that (the fpecific gravity of the new compound being inferior to that of the uncombined water) it immediately changes its place, and allows another stratum of particles to occupy its room. These unite with caloric, and are displaced in their turn. And in this manner the process goes on, till all the particles have combined with caloric; or, which is the fame thing, till the whole of the water is heated.

But supposing the first stratum of particles to remain How heat in their place after their union with caloric, we can passes thro conceive an affinity still to subfift between the new com-folids. pound, thus formed, and caloric. In that case the new compound, which we shall call A, would com-bine with an additional dose of caloric, and form a fecond compound B, differing in feveral respects from the first. We can conceive also the affinity between the first compound A and caloric to be interior to that between water and caloric. In that case, the second stratum of particles of water would separate the additional dose with which the first stratum had united. In this manner would two stratums of particles combine with caloric. The first stratum of particles would combine with another dose of caloric, and form a second compound B as before. But this compound could not now be decomposed by the second stratum of particles,

ric. because they had already united with a dose of caloric; and therefore their affinity for a new dose could be no greater than that of the first stratum of particles. The process of heating could go on no farther. But we can conceive the fecond compound B, into which the first stratum has entered, still to have an affinity for caloric, to combine with a dose of it, and to form with it a third compound C. We can conceive, at the same time, the affinity between the second compound B and caloric to be less than that between the first compound A and caloric. In that case, the second stratum of particles would take this last dose from the first stratum, and form with it a fecond compound B. The third stratum of particles, which is still uncombined with caloric, would now attract this new dole from the fecond stratum, and combine with it. And, supposing the caloric still flowing towards the water, the first stratum would again form the third compound C, by uniting with a fresh dose: this new dose would be again attracted by the second stratum, and the first stratum would again form the third compound C, by uniting with another dose of caloric. Thus three stratums of particles would be combined with caloric; the first stratum would contain three doses, the second stratum two, and the third one. The process of heating would again stop; because now the affinity of the second stratum is no greater than that of the first, nor the affinity of the third ftratum greater than that of the second, nor that of the fourth than that of the third. But we can conceive an affinity still to subfift between caloric and the third compound C, into which the first stratum has entered, and this affinity, at the same time weaker than that between the second compound B and caloric. In that case they would combine and form a fourth compound D. This new dose would be attracted by the second stratum of particles, which would combine with it and form the third compound C; the third stratum would attract it from the lecond, and form with it the fecond compound B; and the fourth stratum would attract it from the third, and enter into the first compound A. The first stratum would again enter into the fourth compound D; which would be again decomposed by the second stratum; and the compound formed by the second stratum, by the third stratum. The fourth compound D would be again formed by the first stratum, and again decomposed by the second stratum. It would be formed a third time, and could not now be decomposed. Four stratums of particles would now have combined with caloric: the first stratum with four doses; the second, with three doses; the third, with two; and the fourth, with one. We can conceive this process to go on exactly in the same manner, till all the particles of water have combined with a dose of caloric. In that case, the quantity of caloric combined with every firatum of particles would form a regular decreafing feries from that part of the water at which the caloric enters to that part which is farthest distant from it. The process of heating would go on very slowly; and the heat of that part of the water which is fartheft distant from the fource of caloric could never be nearly equal to that of the part which is nearest to that This feems in fact to be the manner in which all those solids are heated which are bad conductors of caloric: in all probability it is the way in which all fo-

That caloric combines with bodies merely by means Caloric. of affinity, feems at first fight contrary to fact; for there is no substance whatever which may not be cooled Bodies cook indefinitely merely by furrounding it with other bodies each other which are colder than itself. Place a piece of hot irou, reciprecalfor inflance, in cold water, it is very foon cooled down ly, to the temperature of that liquid. This feems plain enough; the attraction of water for caloric is greater than that of iron: but reverse the experiment; put liot water within cold iron, and the water is cooled in its turn down to the temperature of the iron: to that the iron also has a greater affinity for caloric, as well as the water; which is abfurd.

But it ought to be remembered, that caloric not on- And why. ly possesses affinity, but that it has another property alfo, of which every other species of matter, except perhaps light, seems to be destitute, a repulsion between its own particles. It is necessary for all organised bodies, and probably for all bodies, that they should possels a certain quantity of caloric; and on this account the greatest care has been taken to secure its equal distribution. This seems to be one use at least of its repulfive power; a power which is never destroyed, however closely caloric is united with other bodies. We have shewn already, that this power is increased by diminishing the quantity of surrounding caloric; and when thus increased to a certain degree, it may at last equal, and even exceed, the affinity between the caloric and the bodies to which it is united; and in that case part of the caloric would necessarily fly off. It seems to be in this manner that bodies reciprocally cool each other, and that they have always a tendency to an equilibrium of temperature. Thus steam by cold is converted into water, and water into ice. And the affinity between bodies and that caloric which is employed in regulating the temperature feems to be so weak, that the repulfion between the particles of caloric eafily overcomes it, and restores the equilibrium. But the affinity been some substances and caloric is so great, that no diminution of temperature has been found sufficient to overcome it. I'his is the case, as we have already feen, with oxygen gas.

The specific caloric of bodies seems to depend on Cause of two things; their affinity for caloric, and the distance the diffebetween their particles. For what is temperature but rence in the disposition of a body to part with caloric? The caloric of more caloric a body is disposed to part with, we call its bodies. temperature the higher; the less it parts with when a colder body is applied, its temperature is faid to be the lower. If oxygen gas parts with no caloric to a thermometer which stands at -100, we say its temperature is - 10°; yet we know that even then it contains, in all probability, much more caloric than the mercury in the thermometer does. Now the stronger the affinity between any substance and caloric, the greater quantity of caloric will be required before the repulsion between its particles is sufficient to overcome this attraction; consequently the more caloric is necessary to raise it a given number of degrees. And the farther distant the particles of bodies are, the farther from one another must the particles of caloric be to which they are united; and confequently the weaker must be the repulsion between them.

We cannot deny how new this theory of the action lids are heated. of caloric will appear to those who have been accustom-

Part 1. Calori:

Encycl. Method. Chim. art. Affinité.

29T Caloric hastens folution, and

ed to look upon Dr Crawford's opinions on this subject as fully proved; nor do we pretend that it can be reconciled with these opinions. But this, we hope, is no proof of its falsehood. We think it can be fairly deduced from Dr Black's doctrine of latent heat: we know, too, that Bergman believed caloric capable of combining chemically with bodies: and Morveau has not only embraced the same opinion, but seems to affirm, that all the combinations into which caloric enters are chemical *. And were this question to be decided by authority, we appeal to all the world, whether other three men could be produced to whose decisions one would more willingly fubmit (1). We do not, however, mean to rest its evidence on authority; let it be compared with facts, and put to the test of experiment; and by its correspondence with these let it stand or fall.

12. Caloric both hastens the solution of salts in water, and increases the solvent power of the water; for increases the solvent salt when hot than when cold. The reason that caloric produces these effects is obvious from those properties of it which have been described. It hastens folution by putting the particles of the fluid in motion, and thus bringing all of them in their turn into contact with the falt: for only those particles can act as folvents which are in contact with the falt. It increases the folvent power of the fluid by combining with it, and forming a compound which has a greater affinity for the falt, and which therefore diffolves more of it than the fluid alone would have done. This new compound is deflroyed by cooling; and then the additional dofe of the falt which had been disfolved is precipitated.

> 13. We should come now to the consideration of the two remaining questions proposed at the end of the second chapter, Why do bodies combine with oxygen at one temperature and not at another? And why is caloric necessary to produce this union? But as the difficulty of these questions is not inferior to their importance, we shall delay any attempt to answer them till we come

to treat of affinity.

292 Methods of obtaining caloric.

14. It now only remains to consider the methods by which caloric may be obtained in a fensible state. These methods may be reduced to four; combustion, percusfion, friction, and light: the last of which shall be confidered afterwards.

293 Combuftion explained.

We have feen already, that the combustion of fimple combustibles and metals is merely their combination with oxygen, during which the oxygen parts with the caloric with which it was formerly united. Now the very fame thing takes place in other combustions. The combustible unites with oxygen, which at the same time gives out its caloric. The change then which the combustible body fuffers is not owing to the action of caloric on it, but to its combining with oxygen. The very same change can be brought about without any of the usual phenomena which attend combustion, fimply by presenting the oxygen combined with some other body instead of caloric. Nitric acid, for instance, is a body which contains in it a good deal of oxygen: If phosphorus be mixed with this acid, it attracts part

of the oxygen, and, without any of the usual phenomena which attend combustion, is converted into phospho. ric acid. Strictly speaking, then, combustion is nothing else but the combination of oxygen with the burning body, and the term might therefore be used in every case where fuch an union takes place; and in this fense indeed it is now employed by feveral writers. But the term com- Whether it bustion is in common language confined to those cases ever takes where the oxygen was previously combined with calo-Place when ric, and where a quantity of heat and light become fen-not prefent, fible; and perhaps it would be better, in order to prevent ambiguity, never to employ it in any other fente. We are not yet absolutely certain that caloric and light may not become fensible in other combinations besides those into which oxygen enters. There are other subflances befides oxygen capable of combining with caloric; for instance, hydrogen and azot: and unless their affinity for caloric be greater than for any other fubflance, they may be capable of combining with other fubstances, and separating from caloric, at least the impossibility of this has never yet been demonstrated. It is improper, therefore, to appropriate the word combustion to the combinations of oxygen, till it can be shewn that the phenomena usually denoted by that name are never owing to any other cause. There is even one case in which these phenomena present themselves, in which we are next to certain that oxygen has no share. There is an affinity between fulphur and iron, and a high temperature promotes their union. When thefe substances are mixed together, and heated till they just begin to appear red hot, they combine together, and at the same time, as the Dutch chemists first observed, a good deal of caloric and light is evolved. The very fame phenomena appear in a vacuum, or in any kind of air whatever. The explanation of them is very fimple and obvious. The fulphur or the iron, or perhaps both, had previously been combined with a quantity of caloric; and when they united together, this caloric of course separated from them.

The theory of combustion adopted by the earlier Stahl's the. chemifts was very different from the preceding Stahl, or, of comas has been already explained, confidered combustion bust on by in every inflance as owing to the separation of phlogit the extrica-tion; and this opinion foon became universal. He conton; and this opinion foon became universal. He con-giston. fidered phlogiston as the same thing with the element of fire; which was capable both of becoming fixed in bodies, and of existing in a state of liberty. Two of its properties in this last state were heat and light. The heat and the light, then, which became fensible during combustion, were nothing else, according to Stahl, but two properties of phlogiston or the element of fire. Macquer, to whose illustrious labours several of the most improved important branches of chemistry owe their existence, by Macwas, we believe, the first person who perceived a strik-quer, ing defect in this theory of Stahl. Sir Isaac Newton had proved that light is a body; it was abfurd, therefore, to make it a mere property of phlogiston or the element of fire. Macquer accordingly confidered phlogiston as nothing else but light fixed in bodies. opinion was embraced by a great number of the most

diftin-

(1) The same opinion has been embraced by Seguin, Pictet, Gadolin, and several other philosophers. We did not mention them, because the theory given above differs in a few particulars from theirs. But we have derived much instruction from their ingenious writings; and many of the facts, which we have given, were obtained from them.

diftinguished chemists; and many ingenious arguments were brought forward to prove its truth. But if phlogifton be only light fixed in bodies, whence comes the heat that manifelts itself during combustion? Is this heat merely a property of light? Dr Black proved that heat is capable or combining with, or becoming fixed in bodies which are not combustible, as in ice and water; and concluded of course, that it is not a property but a body. From that time heat or caloric was considered by the greatest number of chemists as a diftinct substance from phologiston.

Soon after this, a phenomenon, which had been obferved from the earliest ages, and which probably, for that very reason, had been neglected, began to be attended to; that combustibles would not burn except in contact with air. Dr Priestley observed, that the air in which combustibles had been suffered to burn till they were extinguished, had undergone a very remarkable change; for no combustible would afterwards burn in it, and no animal could breathe it without fuffocation (K). He concluded, as Dr Rutherford had done before him, that this change was owing to phlogifton; that the air had combined with that substance; and that air was necessary to combustion, by attracting the phlogiston, for which it had a strong affinity. If fo, phlogiston could not be light any more than caloric; for if it separated from the combustible merely by combining with air, it could not furely dif-play itself in the form of light. The question then recurred with double force, What is phlogiston? Dr w- Crawford, of whole ingenious experiments on the specific caloric of bodies we have already given an account, without attempting to answer this question, made a confiderable improvement in the theory of combustion, by supposing that the phlogiston of the combustible combined with the air, and at the same time separated the caloric and light with which that fluid had been previoully united. The heat and the light, then, which appeared during combuttion, existed previously in the air. This theory was very different from Stahl's, and certainly a great deal more fatisfactory. But fill the question, What is phlogiston? remained to be anfwered. Mr Kirwan, who had already raifed himself

important discoveries, and many ingenious investiga- Caloric. tions of some of the most difficult parts of chemistry, attempted to answer this question, and to prove that phlogiston was the same with hydrogen *. The sub- * In his ject was now brought to a flate capable of the most Treatife on complete decision. Does hydrogen actually exist in all 200 combustible substances? and is it separated from them Refuted. during every combustion? The French chemists who answered his treatile, shewed that this is by no means the case; and that therefore there was no proof whatever of the identity of phlogiston and hydrogen. And Mr Kirwan in consequence, with that candour which distinguishes superior minds, gave up his opinion as untenable.

Mr Lavoisier had already put the question, What Existence proof is there of the existence of phlogiston at all? of phlogis-There is only this fingle proof, that substances after ton disprocombustion are different from what they formerly were. ved. That this difference takes place is certainly true; but it is owing, not to the separation of any substance, but to the combination of one. It follows, therefore, that there is no proof whatever of the existence of any fuch substance as phlogiston in nature; and of course we must conclude, that no fuch substance exists (L).

15. It is well known, that heat is produced by the Production percussion of hard bodies against each other. When a of caloric piece of iron is fmartly and quickly thruck with a ham-by percufmer, it becomes red hot; and the production of fparks by the collision of slint and steel is too familiar a fact to require being mentioned. No heat, however, has ever been observed to follow the percussion of liquids, nor of foft bodies which eafily yield to the stroke.

It has long been known, that hammering increases Owing the denfity of metals. The specific gravity of iron be-partly to fore hammering is 7,788; after being hammered, 7,840: condensation, that of platinum before hammering is 19,50; after it, 23,00. Now condensation diminishes the specific caloric of bodies. After one of the clay pieces used in Wedgewood's thermometer has been heated to 1200, it is reduced to one half of its former bulk, though it has lost only two grains of its weight, and its specific caloric is at the same time diminished one third *. But * T. Wedge. we cannot conceive the specific caloric of a body to be wood, Phil. to the first rank among chemical philosophers by many diminished without its giving out at the same time a 1792.

(K) These very observations had been made almost a century before by Mayow; but chemistry was then in its infancy; little attention was paid to them, and they had been forgotten.

(L) Mr Lavoisier was therefore the author of what is called the antiphlogistic theory in chemistry, or the theory which accounts for the phenomena of chemistry without the affishance of phlogiston. It has been so called in opposition to the theory of Stahl, which explained every thing by means of phlogiston, and which is therefore called the phlogiflic theory.

Some chemists have affected to omit Lavoisier's name altogether, when they spoke of the antiphlogistic theory. According to them, that theory was founded upon the experiments and discoveries of other chemists, and Lavoifier had no other merit but that of bringing it into public notice.

That Mr Lavoisier virtually at least claimed several of the discoveries of others, we are forry to be under the necessity of acknowledging; and that many of the experiments, brought forward to disprove the existence of phlogiston, were first made by others, is known to all the world : but it is equally evident, that the first person who actually formed the theory was Lavoisier; and furely the merit lies in that. It is not those who collect the stones, and the timber, and the mortar, but he who lays the plan, and shows how to put the materials together, that is in reality the builder of the house. Who did not know, as well as Newton, that a stone fell to the ground, and that the planets revolved round the sun? and yet, who but Newton could have formed the theory of gravitation? We would not be understood to detract any thing from the merit of the other illustrious philosophers who have adorned the present age, many of whom are at least equal, and some of them superior to Lavoifier: But we are afraid that envy, or some worse motive, guided the pen of one at least of the most active and virulent antagonists of that illustrious and unfortunate philosopher.

1708.

304

to combuf-

quantity of caloric; and we know for certain that caloric is evolved during condensation. A thermometer placed within a condenser rifes several degrees every time air is thrown in +. We can even see a reason for Heil Trans, this. When the particles of a body are forced nearer each other, the repulfive power of the caloric combined with them is increased, and consequently a part of it will be apt to fly off. Now, after a bar of iron has been heated by the hammer, it is much harder and brittler than before. It must then have become denser, and consequently must have parted with caloric. It is an additional confirmation of this, that the same bar cannot be heated a fecond time by percussion until it has been exposed for some time to a red heat. It is too brittle, and flies to pieces under the hammer. Now brittleness seems in most cases owing to the absence of the usual quantity of caloric. Glass unannealed, or, which is the fame thing, that has been cooled very quickly, is always extremely brittle. When glass is in a state of fusion, there is a valt quantity of caloric accumulated in it, the repulsion between the particles of which must of course be very great; so great indeed, that they would be disposed to fly off in every direction with inconceivable velocity, were they not confined by an unufually great quantity of caloric in the furrounding bodies: consequently if this surrounding caloric be removed, the caloric of the glass flies off at once, and more caloric will leave the glass than otherwise would leave it, because the velocity of the particles must be greatly increased. Probably then the brittleness of glass is owing to the deficiency of caloric; and we can fcarcely doubt that the brittleness of iron is owing to the same cause, if we recollect that it is removed by the application of new caloric. Part therefore of the caloric which appears in consequence of percussion seems to proceed from the body ftruck; and this is doubtless the reason why those bodies, the denfity of which is not increased by percus. sion, as liquids and soft substances, are not heated at all. And partly

We fay part of the caloric; because, often at least, part of it is probably owing to another cause. By condensation, as much caloric is evolved as is sufficient to raise the temperature of some of the particles of the body high enough to enable it to combine with the oxygen of the atmosphere. The combination actually takes place, and a great quantity of additional caloric is separated by the decomposition of the gas. That this happens during the collision of flint and steel cannot be doubted; for the sparks produced are merely small during their passage through the air, as any one may the friction of liquids, but then they are too yielding

convince himself by actually examining them. Mr Lane Calon has shewn that iron produces no sparks in the vacuum of an air pump; but Mr Kirwan has observed that they are produced under common fpring water; and we know that iron at a certain temperature is capable of decomposing water.

Part

When quartz, rock crystal (M), or other very hard sparks. ftones, are ftruck against one another, they emit sparks. mitted by If they be often made to emit sparks above a sheet of quartz white paper, there are found upon it a number of smalleliston. black bodies, not very unlike the eggs of flies. These bodies are hard but friable, and when rubbed on the paper leave a black stain. When viewed with a microscope, they seem to have been melted. Muriatic acid changes their colour to a green, as it does that of lavas *. These substances evidently produced the sparks * Lane. by being heated red hot. Lamanon (N) supposes that Journ to they are particles of quartz combined with oxygen. Phys. 11 Were that the case, the phenomenon would be precifely fimilar to that which is produced by the collision of flint and fleel. That they are particles of quartz cannot be doubted; but to suppose them combined with oxygen is contrary to all experience: for these stones never fhew any disposition to combine with oxygen even when exposed to the most violent heat. La Metherie made experiments on purpose to see whether Lamanou's opinion was well founded; but they all turned out unfavourable to it. And Monge ascertained, that the particles described by Lamanon were pure crystal unaltered, with a quantity of black powder adhering to them. He concludes accordingly, that these fragments had Cauled been raifed to fo high a temperature during their pafthis unlarge through the air, that they fet fire to all the minute bodies that came in their way +. We must therefore either suppose that all the caloric was produced by 206. mere condensation, which is not probable, or acknowledge that we cannot explain the phenomenon.

16. Caloric is not only produced by percussion, but Emission also by friction. Fires are often kindled by rubbing of caloring pieces of dry wood fmartly against one another. It is on free well known that heavy loaded carts sometimes take fire by the friction between the axle-tree and the wheel. Now in what manner is the caloric evolved or accumu. Not on lated by friction? Not by increasing the density of the to contain bodies rubbed against each other, as happens in cases of sation, percussion; for heat is produced by rubbing soft bodies against each other, the density of which therefore cannot be increased by that means, as any one may convince himself by rubbing his hand smartly against his pieces of iron heated red hot by uniting with oxygen coat. It is true, indeed, that heat is not produced by

(M) These stones are composed of almost pure silica.

⁽N) This ingenious and unfortunate young man, to whom we are indebted for these facts, fell a victim to his ardour for knowledge. He accompanied La Perouse in his last voyage, and was murdered with the most savage cruelty, together with La Langle and feveral others, by the natives of the island of Maouna. When a man of genius, anxious to acquire honest fame, and a man too so nobly disinterested as Lamanon, thus falls prematurely before he has attained the object of his wishes,

[&]quot;Cut off from nature's and from glory's course! "Which never mortal was fo fond to run,"

who can withhold the tribute of regret and admiration, when they

^{- &}quot; conjecture what he might have proved, And think life only wanting to his fame."

to be subjected to strong friction. It is not owing to the specific caloric of the rubbed bodies decreasing; for Count Rumford found, that there was no fensible decrease +, nor, if there were a decrease, would it be suf. ficient to account for the vast quantity of heat which is

fometimes produced by friction. Count Rumford took a cannon cast folid and rough as it came from the foundery; he caused its extremity to be cut off, and formed, in that part, a folid cylinder attached to the cannon 73 inches in diameter and 9 % inches long. It remained joined to the rest of the metal by a fmall cylindrical neck. In this cylinder a hole was bored 3,7 inches in diameter and 7,2 inches in length. Into this hole was put a blunt steel borer, which by means of horses was made to rub against its bottom; at the fame time a small hole was made in the cylinder perpendicular to the bore, and ending in the folid part a little beyond the end of the bore. This was for introducing a thermometer to meafure the heat of the cylinder. The cylinder was wrapt round with flannel to keep in the heat. 'The borer preffed against the bottom of the hole with a force equal to about 10,000 lb. avoirdupois, and the cylinder was turned round at the rate of 32 times in a minute. At the beginning of the experiment the temperature of the cylinder was 60°; at the end of 30 minutes, when it had made 960 revolutions, its temperature was 130°. The quantity of metallic duft or fcales produced by this friction amounted to 837 grains. Now, if we were to suppose that all the celoric was evolved from these fcales, as they amounted to just $\frac{1}{\sqrt{48}}$ part of the cylinder, they must have given out 948° to raise the cylinder 1°, and consequently 66360° to raise it 70° or to 130°,

which is certainly incredible +.

Neither is the caloric evolved during friction, owing to the combination of oxygen with the bodies themselves or any part of them. By means of a piece of clock-work, Mr Pictet made fmall cups (fixed on the axis of one of the wheels) to move round with confiderable rapidity, and he made various substances rub against the outsides of these cups, while the bulb of a very delicate thermometer placed within them marked the heat produced. The whole machine was of a fize fufficiently fmall to be introduced into the receiver of an air pump. By means of this machine a piece of adamantine spar was made to rub against a steel cup in air: sparks were produced in great abundance during the whole time, but the thermometer did not rife. The fame experiment was repeated in the exhausted receiver of an air pump (the manometer flanding at four lines); no sparks were produced, but a kind of phofphoric light was vifible in the dark. The thermometer did not rife. A piece of brass being made to rub in the fame manner against a much smaller brass cup in air, the thermometer (which almost filled the cup) rose 0,30, but did not begin to rise till the friction was over. This flews us that the motion produced in the air carried off the caloric as it was evolved. In the exhausted receiver it began to rife the moment the friction began, and rofe in all 1,2°. When a bit of wood was made to rub against the brass cup in the air, the thermometer role 0,7°, and on subflituting also a wooden cup it rose 2,1°, and in the exhausted receiver 2,4°, let fur and in air condensed to 13 atmospheres it role 0,5° *. ch 9. If these experiments be not thought conclusive, we

have others to relate, which will not leave a doubt that

the heat produced by friction is not connected with the Caloric. decomposition of oxygen gas. Count Rumford contrived, with his nsual ingenuity, to inclose the cylinder above described in a wooden box filled with water, which effectually excluded all air, as the cylinder itself and the borer were furrounded with water, and at the fame time did not impede the motion of the inflrument. The quantity of water amounted to 18,77 lbs. avoirdupois, and at the beginning of the experiment was at the temperature of 60°. After the cylinder had revolved for an hour at the rate of 32 times in a minute, the tempes rature of the water was 107°; in 30 minutes more it was 178°; and in 2 hours and 30 minutes after the experiment began, the water actually boiled. According to the computation of Count Rumford, the caloric produced would have been sufficient to heat 26,58 lbs. avoirdupois of ice-cold water boiling hot; and it would have required 9 wax candles of a moderate fize, burning with a clear flame all the time the experiment lafted, to have produced as much heat. In this experiment all accefs of water into the hole in the cylinder where the friction took place was prevented. But in another experiment, the refult of which was precifely the same, the water was allowed free access +.

The caloric, then, which appears in consequence of ibid. friction, is neither produced by an increase of the den- And confity, nor by an alteration in the specific caloric of the fequently fubstances exposed to friction, nor is it owing to the de-at present composition of the oxygen of the atmosphere-Whence in xplicathen is it derived? This question we are altogether un-ble. able to answer. We cannot, however, think, that the conclusion which Count Rumford is disposed to draw from his experiments is warranted by the premifes. He sup-This no poses, that because we cannot explain the manner that proof that caloric is accumulated by friction, there is no fuch fub caloric is stance as caloric at all, but that it is merely a peculiar not a body. kind of motion. We would beg leave to ask, how the facts mentioned in the former part of this chapter, many of which were furnished by this ingenious philosopher himself, and all of which combine to render the existence of caloric as a substance probable, can be de-

ftroyed and fet afide, merely because there are other phenomena in nature connected with caloric which cannot be accounted for? Were it possible to prove that the accumulation of caloric by friction is incompatible with its being a fubstance, in that case Count Rumford's conclusion would be a fair one; but this furely has not been done. We are certainly not yet fufficiently acquainted with the laws of the motion of caloric (allowing it to be a substance) to be able to affirm with certainty that friction could not cause it to accumulate in the bodies rubbed. This we know at least to be the case with electricity. Nobody has been hitherto able to demonstrate, in what manner it is accumulated by friction; and yet this has not been thought a fufficient

reason to deny its existence. Indeed there feems to be a very close analogy between Analogy caloric and electric matter. Both of them tend to diffuse hetween themselves equally, both of them dilate bodies, both of electricity. them fuse metals, and both of them kindle combustible substances. Mr Achard has proved, that electricity can be substituted for caloric even in those cases where its agency feems peculiarly necessary; for he found that, by constantly supplying a certain quantity of the electric fluid, eggs could be hatched just as when they are

Caloric. kept at the temperature of 1039. An accident indeed prevented the chickens from actually coming out; but they were formed and living, and within two days of bursting their shell. Electricity has also a great deal of influence on the heating and cooling of bodies. Mr Pictet exhausted a glass globe, the capacity of which was 1200,199 cubic inches, till the manometer within it stood at 1,75 lines. In the middle of this globe was suspended a thermometer which hung from the top of a glass rod fixed at the bottom of the globe, and going almost to its top. Opposite to the bulb of this thermometer two lighted candles were placed, the rays of which, by means of two concave mirrors, were concentrated on the bulb. The candles and the globe were placed on the fame board, which was supported by a non-conductor of electricity. Two feet and a half from the globe there was an electrifying machine, which communicated with a brass ring at the mouth of the globe by means of a metallic conductor. This machine was kept working during the whole time of the experiment; and confequently a quantity of electric matter was conflantly passing into the globe, which formed an atmosphere not only within it, but at some distance round, as was evident from the imperfect manner in which the candles burned. When the experiment began the thermometer stood at 49,8°. It rose to 70,2° in 732". The fame experiment was repeated, but no electric matter thrown in; the thermometer role from 49,8° to 70,2° in 1050"; fo that the electricity hastened the heating almost a third. In the first experiment the thermometer rose only to 71,3°, but in the second it role to 77°. This difference was doubtless owing to the candles burning better in the second than the first experiment; for in other two experiments made exactly in the same manner, the maximum was equal both when there was and was not electric matter prefent. These experiments were repeated with this difference, that the candles were now infulated, by placing their candlesticks in dishes of varnished glass. The thermometer rose in the electrical vacuum from 52,2° to 74,7° in 1050"; in the fimple vacuum in 965". In the electrical vacuum the thermometer rofe to 77°; in the fimple vacuum to 86°. It follows from these experiments, that when the globe and the candles communicated with each other, electricity hastened the heating of the thermometer; but that when they were infulated * Pielet fur separately, it retarded it *. One would be apt to sufbe Feu, ch. 6. pect the agency of electricity in the following experiment of Mr Pictet: Into one of the brass cups formerly described, a small quantity of cotton was put to pre-

vent the bulb of the thermometer from being broken. As the cup turned round, two or three fibres of the cotton rubbed against the bulb, and without any other friction the thermometer rose sive or six degrees. A greater quantity of cotton being made to rub against

+ Ibid. ch. 9. the bulb, the thermometer rose 15 degrees +.

We do not mean to draw any other conclusion from Electricity these facts, than that electricity is very often concerned agent in the in the heating of bodies, and that probably some such heating of agent is employed in accumulating the heat produced bodies by by friction. Supposing that electricity is actually a friction.

fubstance, and taking it for granted that it is different from caloric, does it not in all probability contain caloric as well as all other bodies? Has it not a tendency to accumulate in all bodies on friction, whether conductors or non-conductors? May it not then be accumuilated in those bodies which are rubbed against one another? or, if they are good conductors, may it not pais through them during the friction in great quantities? May it not part with some of its caloric to these bodies, either on account of their greater affinity or some other cause? and may not this be the source of the caloric which appears during friction?

CHAP. VI. Of LIGHT.

By means of light bodies are rendered visible. Light New has been confidered as a fubstance composed of small the particles moving in ftraight lines from luminous bodies light with inconceivable rapidity. The discoveries of Newton established this opinion on the firm basis of mathematical demonstration; and fince his time it has been generally embraced. Huyghens, indeed, and Euler, advanced another (o). They confidered light as a fubtile fluid, filling all space, which rendered bodies visible by its undulations. But they supported their hypothefis rather by starting objections to the theory of New. ton, than by bringing forward direct proofs. Their objections, even if valid, instead of establishing their own opinions, would prove only that the phenomena of light are not completely understood; a truth which no man will refuse to acknowledge, whatever side of the question he adopts. Newton and his disciples, on the contrary, have shewn, that the known phenomena of light are inconfisent with the undulations of a fluid, and have brought forward a great number of direct arguments, which it has been impossible to answer, in support of their theory. It can hardly be doubted, therefore, that the Newtonian theory of light is the true

Dr Bradley, who, by a number of very accurate ex-Veloc periments, and a process of reasoning peculiarly ingenialight. ous, discovered the aberration of light of the fixed stars, has shewn from it that the velocity of light is to that of the earth in its orbit as 10313 to 1. Light therefore moves at the rate of 195218 miles in a fecond.

Light, by means of a prism, may be separated into pivis feven rays, differing from each other in colour; red, into fe orange, yellow, green, blue, indigo, violet. None of rays, these are capable of farther decomposition. Marat, indeed, pretended that he had reduced them to three; but his experiments are now known to have been merely philosophical frauds.

When light passes obliquely into a denser medium, it Differ is refracted towards the perpendicular; when into a ra-in refig rer, from the perpendicular. Sir Isaac Newton disco-bility, vered that the rays differed in their refrangibility in the order in which they have been named, the red being the least, the violet the most refrangible. Mr Blair has observed, that the ratios of the remanging of the different rays, though not their order, vary somewhat in the point of the Phil.

When iii.

⁽o) Dr Franklin did the fame, without taking any notice of these philosophers, of whose opinions perhaps he was ignorant. See Tranf. Philad. III. 5.

Light.

Pholii.

When light passes within a certain distance of a body, parallel to which it is moving, it is bent towards it; of on, when it paties at a greater distance, it is bent from it, and ion, The first of these properties is called inflection, the sewhen it passes at a greater distance, it is bent from it. cond deflettion. Now the rays differ in these properties in the order in which they were named; the red being most, the violet least inflexible and deflexible. was suspected by David Rittenhouse *, but was first demonstrated by the ingenious experiments of Mr Brougham +.

When light falls upon a visible body, some of it is reflected back; and the more polished or the whiter any furface is, the more light it reflects. The rays of light differ also in reflexity (see Reflexity, Suppl.), the red being the most, the violet the least reflexible. discovery we owe to the same ingenious gentleman ‡.

These properties of light constitute the subject of Oprics; to which we refer those who wish to see them investigated. We mention them here because they prove that light is acted on by other bodies, that it is fubjected to the laws of attraction, and, confequently,

that it possesses gravity.

2. The particles of light seem also, like those of caloric, to possess the property of repelling one another; at least their rapid motion, in all directions, from luminous bodies, seems to be owing to some such property.

3. Light is capable of entering into bodies, and reof en- maining in them, and of being afterwards extricated withtho out any alteration. Father Beccaria, and several other philosophers, have shown us by their experiments, that there are a great many substances which become luminous after being exposed to the light. This property was discovered by carrying them instantly from the light into a dark place, or by darkening the chamber in which they were exposed. Most of these substances, indeed, lose this property in a very short time, but they recover it again on being exposed to the light; and this may be repeated as often as we please. We are indebted to Mr Canton for some very interesting experiments on this subject, and for discovering a composition which possesses this property in a remarkable degree. He calcined some common oyster shells in a good coal fire for half an hour, and then pounded and sifted the purest part of them. Three parts of this powder were mixed with one part of the flowers of fulphur, and rammed into a crucible which was kept red hot for an hour. The brightest parts of the mixture were then scraped off, and kept for use in a dry phial well stopped. When this composition is exposed for a few seconds to the light, it becomes fufficiently luminous to enable a perfon to distinguish the hour on a watch by it. After fome time it ceases to shine, but recovers this property on being again exposed to the light. Light then is not only acted upon by other bodies, but it is capable of uniting with them, and afterwards leaving them without any change.

It is well known that light is emitted during combustion; and it has been objected to this conclusion, that these bodies are luminous only from a flow and imperceptible combustion. But surely combustion cannot be suspected in many of Father Beccaria's experiments, when we reflect that one of the bodies on which they were made was his own hand, and that many of the others were altogether incombustible; and the phenomena observed by Mr Canton are also incompatible

SUPPL. VOL. I. Part I.

with the notion of combustion. His pyrophorus shone only in consequence of being exposed to light, and lost that property by being kept in the dark. It is not exposure to light which causes substances capable of combuition at the temperature of the atmosphere to become luminous, but exposure to air. If the same temperature continues, they do not ceafe to shine till they are confumed; and if they cease, it is not the application of light, but of caloric, which renders them again luminous: but Canton's pyrophyrus, on the contrary, when it had loft its property of shining, did not recover it by the application of heat, except it was accompanied by light. The only effect which heat had was to increase the separation of light from the pyrophorus, and of course to thorten the duration of its luminousnefs. Two glass globes, hermetically sealed, containing each some of this pyrophorus, were exposed to the light and carried into a dark room. One of them, on being immerfed in a bason of boiling water, became much brighter than the other, but in ten minutes it ceafed to give out light: the other remained visible for more than two hours. After having been kept in the dark for two days, they were both plunged into a bason of hot water; the pyrophorus which had been in the water formerly did not shine, but the other became luminous, and continued to give out light for a confiderable time. Neither of them afterwards thone by the application of hot water; but when brought near to an iron heated so as scarcely to be visible in the dark, they suddenly gave out their remaining light, and never shone more by the same treatment: but when exposed a second time to the light, they exhibited over again precifely the same phenomena; even a lighted candle and electricity communicated fome light to them. Surely these facts are altogether incompatible with combustion, and fully sufficient to convince us that light alone was the agent, and that it had actually entered into the luminous bodies.

It has been questioned, indeed, whether the light emitted by pyrophori be the same with that to which they are exposed. Mr Wilson has proved, that in many cases at least it is different, and in particular that on many pyrophori the blue rays have a greater effect than any other, and that they cause an extrication of red light. Mr de Groffer has shewn the same thing with regard to the diamond, which is a natural pyrophorus . Still, however, it cannot be questioned that four. do the luminousness of these bodies is owing to exposure Phys. xx. to light, and that the phenomenon is not connected with 270. combustion.

But light appears capable, not only of entering into And of bebodies, but of combining with them chemically. The ing combiphenomena of the photphori feem to be instances of ned with this, and a great many facts concur to prove that light them. enters into the composition of oxygen gas. When vegetables grow in the light, they give out oxygen gas; but no oxygen is extricated in the dark, even though heat be applied to. From this it is evident, that the fe- Priofley paration of this gas from plants, or perhaps the decom and Ingen-polition of the water which they contain, depends upon Loufz. the action or light; and that as this decomposition is chemical, the light to produce it must either combine with the oxygen or the hydrogen, or at least contribute to the combination of some other substance with one or other of them. When the oxyds of gold or filver are

and at the same time a quantity of oxygen gas is extri-\$ Bertbollet. cated \$. In this case, it is evident that the light must either combine with the oxygen or the metals. If a quantity of nitric acid be exposed for some time to the light, it becomes yellow, as is well known, and a quantity of oxygen gas is found floating on its top. If it be now carried to a dark place, the oxygen is gradually absorbed, and the acid becomes colourless. In this case, nitric acid is decomposed by means of light, and resolved into nitrous acid and oxygen gas. The light must therefore have combined either with the nitrous acid or the oxygen. But no change whatever appears to liave been produced in the nitrous acid; for if it be obtained in the dark by any other process, it has precisely the fame properties. The oxygen, on the contrary, is converted into a gas. It is more probable, then, that the light has combined with the oxygen than with the acid. Hence there is reason to suspect that light makes one of the ingredients of oxygen gas. Caloric has already been shewn to make another ingredient.

323 Light pears du-

During combustion, a quantity of light as well as cawhich ap- loric is almost always evolved. We must conclude, therefore, that light makes a part of the composition cither of the combustibles themselves, or of the oxygen gas posed com. with which they unite. We have already shewn, that bined with oxygen gas probably contains light; and this probabioxygen gas lity is confirmed by another fact. Substances may be combined with oxygen without the emission of any light, provided the oxygen be not in the flate of a gas. If phosphorus, for instance, be put into nitric acid, it attracts oxygen, and is converted into phosphoric acid without the emission of any light. Now if the light which appears during combustion had been combined with the combustible, it ought to appear in all cases when that combustible is united with oxygen, whether the oxygen has previously been in the state of a gas or not. But as this is not the cafe, we may certainly infer, that the light which appears during combustion is extricated, not from the combustible, but from the oxygen gas. And this feems at prefent to be the opinion of the greater number of philosophers.

But we must acknowledge, that this conclusion is not without its difficulties, and difficulties, too, which, in the present state of chemistry, it does not seem possible

In the first place, it is evident, that light may be pro-

to furmount.

Difficulties duced curing combustion, though the oxygen be not in the state of a gas: For if nitric acid be poured upon oil of turpentine, the oil takes fire, and burns with the greatest rapidity, and a great deal of light is emitted. This combustion is occasioned by the oxygen of the acid combining with the ingredients of the oil. It follows, therefore, if the light emitted was previously combined with the oxygen, that oxygen must contain light when not in the state of a gas. Mr Proust has shown that a great variety of fimilar combustions may be produced. But what is very remarkable, by proper caution the very fame combinations may be made to take place without the visible emission of any light. In that cafe they take place very flowly, as happens also when phosphorus decomposes nitric acid; so that the emis-

fion or non-emission of light seems to depend not upon

the state of the oxygen, so much as upon the rapidity

or flowness of the combination. It is true, indeed, as

exposed to light, they are reduced to the metallic state *, the late Dr Hutton of Edinburgh observed, that light may be emitted in thesc slow combinations though it be not visible; and this is very probably the case: but then the proof is destroyed that light exists in oxygen gas, from its not appearing during combinations in which the oxygen did not exist previously in a gaseous

> In the fecond place, the colour of the light emitted during combustion differs almost always according to the combustible. During the combustion of phosphorus, tin, and zinc, the light emitted is white; during that of fulphur and bifmuth, blue. Now if this light were united with the oxygen, why does it not appear always of the same colour, whatever be the combuttible?

> In the last place, the phenomena of phosphori shew that light is capable of entering into other bodies as well as oxygen gas; and the emission of light on the collision of two flint stones, when no oxygen gas can be decomposed, is a proof of the same kind, which cannot be got over.

> In the present state of chemistry, therefore, it cannot be concluded, that the light emitted during combustion does not exist in the combustibles as well as in the

4. Light has the property of heating bodies. All Light bodies, however, are not heated by it. Those which bodies. are perfectly transparent, or which allow all the light: to pass through them, suffer no alteration in their temperature. Thus light may be concentrated upon water or glass without producing any effect. Neither does it produce much change upon those bodies (mirrors for instance) that reflect all or nearly all the light which falls upon them. And the imallness of the alteration of temperature is always proportional to the fineness of the polish, or, which is the same thing, to the quantity of light which is reflected. So that we have reason to conclude, that if a substance could be procured which reflected all the light that fell upon it, the temperature of fuch a fubstance would not be at all affected by light falling upon it. Dr Franklin exposed upon fnow pieces of cloth of different colours (white, red, blue, black,) to the light of the fun, and found that they funk deeper, and confequently acquired heat, in proportion to the darkness of their colour. Now it is well known that dark-coloured bodies, even when equally expoted to the light, reflect less of it than those which are light-coloured. But fince the fame quantity falls upon each, it is evident that dark-coloured bodies must absorb and retain more of it than those which are light-coloured. That fuch an abforption actually takes place is evident from the following experiment. Mr Thomas Wedgewood placed two lumps of luminous or phosphorescent marble on a piece of iron heated just under redness. One of the lumps of marble which was blackened over gave out no light; the other gave out a great deal. On being exposed a second time in the fame manner, a faint light was feen to proceed from the clean marble, but none at all could be perceived to come from the other. The black was now wiped off, and both the lumps of marble were again placed on the hot iron: The one that had been blackened gave out just as little light as the other f. In this case, the & Phil. light which ought to have proceeded from the lumi- Trans. nous marble disappeared: it must therefore have been

this opinion.

flopped in its passage out, and retained by the black paint. Now black substances are those which absorb the most light, and they are the bodies which are most heated by exposure to light. Cavallo observed, that a thermometer with its bulb blackened stands higher than one which has its bulb clean, when exposed to the light of the sun, the light of day, or the light of a lamp *. 780. Mr Pictet made the same observation; and took care to afcertain, that when the two thermometers were allowed to remain for some time in a dark place, they acquired precisely the same height. He observed, too, that when both thermometers had been raifed a certain number of degrees, the clean one fell a good deal faster than the other ‡. But it is not a small degree of heat alone which can be produced by means of light. When its rays are concentrated by a burning glass, they are capable of fetting fire to combustibles with ease, and even of producing a temperature at least as great, if not greater, than what can be procured by the most violent and best conducted fires. In order to produce this effeet, however, they must be directed upon some body capable of absorbing and retaining them; for when they are concentrated upon transparent bodies, or npon fluids, mere air for instance, they produce little or no effect whatever. We may conclude, therefore, in general, that in all cases when light produces heat it is absorbed.

5. All hodies become luminous when their temperature is raised a certain number of degrees. No fact is more familiar than this; so well known indeed is it, that little attention has been paid to it. When a body becomes luminous by being heated in a fire, it is faid in common language to be red bot. It follows from all the experiments hitherto made, that the temperature at which they become red hot is nearly the same in all bodies. - It seems to be pretty near 8000. A red hot body continues to shine for some time after it has been taken from the fire and put into a dark place. The conflant accession, then, either of light or heat is not necessary for the shining of bodies: but if a red hot body be blown upon by a strong current of Wedge- air, it ceases to shine immediately f. Consequently the Phil. moment the temperature of a body is diminished by a 61792 certain number of degrees, it ceases to be luminous.

Whenever a body reaches the proper temperature, it becomes luminous, independent of any contact of air; for a piece of iron wire becomes red hot while immerfed

in melted lead +. To this general law there is one remarkable exceppt the tion. It does not appear that the gases become luminous even at a much higher temperature. The following ingenious experiment of Mr T. Wedgewood point of view. He took an earthen ware tube B (fig. make feveral turns in the large crucible C, which was were, that the one is in a flate of liberty, the other in

filled with fand. To one end of this tube was fixed the pair of bellows A; at the other end was the globular veffel D, in which was the passage F, surnished with a valve to allow air to pass out, but none to enter. There was another opening in this globular veffel filled with glass, that one might fee what was going on within. The crucible was put into a fire; and after the fand had become red hot, air was blown through the earthen tube by means of the bellows. This air, after passing through the red-hot fand, came into the globular veffel. It did not shine; but when a piece of gold wire E was hung at that part of the vessel where the earthen ware tube entered, it became faintly luminous. proof, that though the air was not luminous, it had been hot enough to raise other bodies to the shining tempe-

6. Thus it appears that light and heat reciprocally Enquiry inproduce each other; that the fixation of light in bodies to the cause always produces heat, and that the application of a fuf- of these ficiently ftrong heat always occasions the extrication of phenomena light. Are heat and light, then, owing to the same cause? Does light become caloric merely by being fixed in bodies? and does caloric assume the appearance of light whenever it is extricated from them? In fhort, are caloric and light merely names for the same substance, called caloric when it is fixed in bodies, and light when in a state of liberty?

To these questions it may be answered, That if caloric and light were one and the fame fubstance, they ought to produce precisely the same effects. Now this is not the case: a black body is not heated sooner by mere caloric than any other, though the contrary takes place when both are exposed to the light *. Heat * T. Wedge. cannot make growing vegetables exhale oxygen gas, Tranf.1792. though light does it almost instantaneously. When oxy-muriatic acid (a compound of oxygen and muriatic acid) is exposed to the light, a quantity of oxygen gas flies off, and nothing remains but common muriatic acid. Light then decomposes this acid; for if you wrap up a bottle in black cloth, so as to exclude light, and then expose it equally to the sun, no such decomposition takes place. Now this decomposition cannot be produced by mere caloric. If the acid be heated, it fimply evaporates without being altered. Chaptal has proved (P), that the rays of light directed on certain parts of glaffes, containing folutions of falts, caufe them to crystallize in that part in preference to any other +. These observations have been confirmed and + Mem. extended by Mr Dorthes ‡. Now caloric produces no Toulouse, iii. fuch effects, nor has the temperature any influence on Ann. de the phenomenon.

'I'hese facts are sufficient to shew that light and calofeems to fet the truth of this exception in a very clear ric, even when they have entered into bodies, produce different effects, and that therefore they have different 5.), bent so in the middle that it could be sunk, and properties(Q). But if the only difference between them Nn2

(P) Petit made the same observations in 1722. See Memoirs of the Academy of Sciences for that year, p. 95.

(Q) We must acknowledge, however, that the following ingenious experiments of Professor Pictet might be adduced, to prove that light and caloric possess at least one property in common, that of moving in straight lines. He placed two concave mirrors of tin, of nine inches focus, at the distance of twelve feet two inches from one another. In the focus of one of them he placed a ball of iron two inches in diameter, heated so as not to be

that of combination, the moment light entered a body it ought to be no longer light but caloric, and confequently ought to produce precifely the same effects with caloric: And fince this is not the cafe, we are warranted furely to conclude that light and caloric are not the same, but different substances. How then does caloric occasion the appearance of light, and light that of caloric?

329 Supposed owing to caloric.

We have seen already, that there is no body in nature which does not contain caloric; and light has fuch the nurual an influence upon every thing, it produces fuch imporrepullion of tant changes upon the animal and vegetable kingdoms, it can be extricated from such a vast number of bodies, that in all probability we may conclude, with regard to it also, that it exists in all, or in almost all, the bodies in nature. We have no means of ascertaining either the quantity of light or of caloric that exists in bodies; but if we were to judge from the quantity which appears during combultion, we must reckon it very confiderable. Now, may there not exist a repulsion between the particles of caloric and light? It is not easy, at least, to see why light slies off during combustion with fuch rapidity, if this be not the case. If such a repulfion actually exists, it will follow that caloric and light cannot be accumulated in the same body beyond a certain proportion. If the caloric exceed, it will tend to drive off the light; if the light, on the contrary, happens to prevail, it will displace the caloric.

If caloric and light actually exist in all bodies, there Light must be an affinity between them and all other hodies; and this affinity must be so great, as to render ineffectual the repulsion which exists between light and caloric. Let us suppose now, that these two substances exist in all bodies in certain proportions, it will follow, that the more either of caloric or light is added to any body, the stronger must the repulsion between their particles become; and if the accumulation be still going on, this repulsion will soon become great enough to balance their affinity for the body in which they exist, and confequently will dispose them to fly off. If caloric, for instance, be added to a body, whenever the body arrives at a certain temperature it becomes luminous. because part of the light which was formerly combined with it is driven off. This temperature must depend partly upon the affinity between the body and caloric, and partly upon its affinity for light. Pyrophori, for instance, the affinity between which and light does not feem to be very great, become luminous at a very moderate temperature. This is the case with the pyrophorus of Canton. A great many hard bodies become luminous when they are exposed to a moderate heat; fluor, for instance, carbonat of barytes, spar, sea shells, and a great many others, which are enumerated by Mr Thomas Wedgwood *.

The fame ingenious gentleman has observed, that Trans. gold, filver, copper, and iron, become luminous when 1792, P.

visible in the dark; in the other was placed the bulb of a thermometer. In fix minutes the thermometer rose from 4° to 14° (Reaumur). A lighted candle, which was substituted for the ball of iron, made the thermometer rife in one experiment from 4,6° to 14°; in another, from 4,2° to 14,33. In this case both light and heat appeared to act. In order to separate them, he interposed between the two mirrors a plate of clear glass. Before the interposition of the glass, the thermometer had risen from 2° to 12°, where it was stationary. After the interposition of the glass it funk in nine minutes to 5,7°; and when the glass was again removed it rose in seven minutes to 11,1°; yet the light which fell on the thermometer did not feem at all diminished by the glass. Mr Pictet therefore concluded, that the caloric had been reflected by the mirror, and that it had been the cause of the rise of the thermometer. In another experiment, a glass matrass was substituted for the iron ball, nearly of the same diameter with it, and containing 2044 grains of boiling water. Two minutes after a thick screen of filk, which had been interposed between the two mirrors, was removed, a Fahrenheit's thermometer, which was in the other focus, rose from 47° to 501; and the moment the matrass was removed from the focus the thermometer again descended. On repeating the experiment, with this variation, that the bulb of the thermometer was blackened, it rose from 51 to 55t.

The mirrors of tin were now placed at the distance of 90 inches from each other; the matrass with the boiling water in one of the foci, and a very fenfible air thermometer in the other, every degree of which was equal to zoth of a degree of Reaumur. Exactly in the middle space between the two mirrors there was placed a very thin common glass mirror, suspended in such a manner that either side could be turned towards the matrass. When the polished fide of this mirror was turned to the matrafs, the thermometer rose only 0,5°; but when the fide covered with tinfoil, and which had been blackened with ink and smoke, was turned toward the matrals, the thermometer rose 3.5°. In another experiment, when the polished side of the mirror was turned to the matrass, the thermometer rose 3°, when the other side 9,2°. On rubbing off the tinfoil, and repeating the experiment, the thermometer rose 18°. On substituting for the glass mirror a piece of thin white pasteboard of the same dimensions with it, the thermometer rose 100. On putting a matrais full of snow into one of the foci (the mirrors in this experiment were 10 feet distant from each other), the air thermometer funk several degrees, and rose again when the matrass was removed. When nitric acid was poured on the snow, the thermometer sunk 5° or 6°

Taking it for granted that thefe experiments proved the motion of caloric in straight lines like light, Mr Pietet endeavoured to discover the velocity of its motion. For this purpose he placed two concave mirrors at the distance of 69 feet from each other; the one of tin as before, the other of platter gilt, and 18 inches in diameter. Into the focus of this last mirror he put the air thermometer, and the bullet of iron heated as before into that of the other. A few inches from the face of the tin mirror there was placed a thick fcreen, which was removed as foon as the bullet reached the focus. The thermometer rofe the inftant the fcreen was removed without any perceptible interval: hence he concluded, that the time caloric takes in moving 69 feet is too short to be measured. See Pilet sur le Feu, chap. iii. wa boo. To that a kepala and made to agod an

heated in times inverfely proportional to their specific calories to. Now the specific calories of these metals are in the following order:

Copper, Silver,

They become luminous, therefore, when exposed to the same degree of heat, in the following order:

Gold, Silver, Copper, Iron.

Now the smaller the specific caloric of any body is, the less must be the quantity of caloric necessary to raile it a given number of degrees; the fooner therefore must it arrive at the temperature at which it gives out light. It was natural to expect, then, if the emission of light from a body by the application of heat be owing to the repulsion between caloric and light, that those bodies should become luminous soonest in which that repulsion increases with the greatest rapidity; and this we see is precisely the case. The only question to be determined before drawing this conclusion is, Whether the same quantity of caloric entered all of them? That depends upon their conducting power, which, according to Ingenhoufz, is in the following order:

Silver, Gold, Copper, Iron.

We sce, then, that this conducting power is nearly in the order in which these metals become luminous; so that the greatest quantity of caloric would enter those which become soonest luminous. Now this is just what ought to happen, provided the expulsion of light from a luminous body, by the application of heat, beowing to the repulsion between the particles of caloric

and light.

The repulsion between the different rays of light and caloric does not feem to be equal: the repulfions between the blue rays and caloric feems to be greater than that between the red rays and caloric; and the repulsion between all the rays and caloric feems to be directly as their refrangibility: accordingly, when heat is applied to a body, the blue rays escape sooner, and at a lower temperature, than the red rays and others which are most refrangible. When sulphur, for instance, is burnt at a low temperature, the colour of the flame is blue; and when examined by the prism it is found to confift of the violet, indigo, blue, and sometimes of a fmall quantity of the green rays *; but when this fub- * Morgan, stance is burnt at a high temperature the colour of the Phil. Trans. flame is white, all the rays separating together. When 1785.

We must observe, with regard to these experiments, that the idea that caloric can be resected, and that it can move in straight lines like light, or that there is such a thing as radiant heat, to use the phrase of Lambert and Scheele, is directly contrary to the experiments of Count Rumford, formerly described; by which he shewed the incapacity of various bodies to conduct heat; for if caloric could move in straight lines through transparent mediums, it would be abfurd to fay that either air, or water, or oil, was a non-conductor of it. But these bodies have in fact been found to be non-conductors; and therefore it must follow unavoidably, that there is no fuch thing as radiant caloric. Consequently, if the experiments of Mr Pictet can be explained, on the supposition that light and not caloric was the agent, that alone will be fufficient to exclude them from ranking as proofs of the identity of heat and light. Now this has been done with a great deal of ingenuity by the late Dr James Hutton of Edinburgh, in his treatise on the Philosophy of Light, Heat, and Fire.

He had previously convinced himself, by a number of experiments, that the different species of light possessed very different degrees of intenfity when measured by the eye and the thermometer. He rendered light of different colours equally intense to the eye, by varying the distance from the luminous body till he could just read by the light of it. In this way he compared the red light from a fire of coals with the white light of stame, and found, that when they were equally powerful in affording vision, the red was by far the most powerful in producing heat. When a body is heated to incandescence, it emits first the white or compound light; but as it cools, the light which it emits becomes of the red species, and this is the last which disappears. As the body cools, therefore, the power of its light to produce heat does not diminish so fast as its power to produce vision; confequently, when this last ccases entirely, the other may still in a certain degree remain. We may suppose, therefore, that the iron ball in Mr Pictet's experiments, after it had loft all light to the eye, continued still to emit rays, which, though they made no impression on that organ, had power to produce heat, and that it was these rays collected by the mirrors that raised the thermometer. What confirms this is, that when the bulb of. the thermometer was blackened it rose higher than at other times; for caloric, as has been already mentioned, would have produced no fuch effect. As to the effect of the matrals of water, it is explained, by fuppoling that all bodies, raised to a certain temperature, emit rays of light, whether they have been heated red hot or

As to the effect of the fnow in lowering the thermometer, which was certainly a very fingular and unlooked for effect, Dr Hutton explains it, by supposing that all bodies emit rays of light, whatever their temperature is, and that this irradiation diminishes as their temperature diminishes. On that supposition, it is evident that the temperature of the thermometer, like that of all other bodies, is maintained partly by the irradiation of invilible light from the furrounding bodies-It must therefore, fince it is placed in the focus of one of the mirrors, be affected by whatever body is placed in the focus of the other. If that body be colder than the furrounding bodies, less light will be irradiated from it and thrown upon the thermometer; consequently the thermometer will be de-

pressed till the deficiency is supplied by some other channel. Such is the ingenious hypothesis by which Dr Hutton has explained the experiments of Mr Pictet; and the explanation, though it is not without very confiderable difficulties, must be allowed at least to be the most plaufible which has hitherto been given, and to be highly deferving of being put to the test of experiment.

bodies have continued to burn for some time, they may be supposed to have lost the greater part of the most refrangible rays; hence the red appearance of bodies, chargoal for instance, that have burnt for some time, the only rays which remain to separate being the orange, † Morgan, yellow, and red †.

1785.

The blue rays feem not only to repel caloric with greater force, but likewife to have a greater affinity for other bodies than the red rays have; for they decompose the oxyd of filver (or rather the muriat of filver) much fooner, and to a greater extent, than the red \$ Sennebier. rays ‡: hence we fee the reason why the application of the blue rays to Mr Wilson's pyrophori and to the dia-

mond causes an extrication of red rays.

We have feen already, that the gases are not heated red hot by the application of heat. It would follow from this, that the gases do not contain light: but the contrary is certain; for light is actually extricated during the combustion of hydrogen, and must therefore have existed either in the oxygen or hydrogen gas, or in both. Probably therefore the reason that heat does not extricate light from the gafes is, that the affinity between their bases and light is exceedingly strong: it would therefore require a more than usual temperature to produce its extrication; and on account of the great dilatability of these gases, which always tends to diminish the repulsion between the caloric and light, this temperature cannot be applied. It is easy to see, upon the supposition that there exists a repulsion between caloric and light, why the accumulation of light should produce heat, and why light only occasions heat in those bodies that absorb it.

Such is the theory of the cause of the reciprocal extrication of light and caloric by the application of these fubstances respectively to bodies, which has been propofed by feveral ingenious chemists (R); and we acknowledge frankly, that it appears to us by far the most plausible of all the explanations of this phenome-

non with which we are acquainted.

It is not, however, beyond the reach of objections, and objections too, we are afraid, altogether incompatithis theory ble with its truth. Were the repulsion between caloric and light the only cause of the luminousness of hot bodies, the continual application of heat would furely in time separate the whole of the light which was comhined with the body, and then it would cease to be lu-

that bodies ever cease to become luminous by the con- Light tinued application of hear. Claveus kept melted, and confequently red hot, gold for months in a furnace; but he does not fay that its luminousnels was diminished, far less destroyed; and had such a remarkable phenomenon taken place, certainly he would not have failed to inform us; but so far from that, he expressly fays that it fuffered no alteration (s) \$.

Whether light would continue to extricate a great Boyle, in deal of caloric during so long a time has never been 208. tried: but we have no reason for supposing that its power to produce that effect is ever exhaufted; for bodies, after being exposed to the fun for years, and even for ages, are just as much heated by it as ever. But these effects, far from being inexhaustible, ought, according to the theory, to come very speedily to an end. It is certainly probable, then, as other philosophers have supposed, that though light and caloric are not precifely one and the same substance, they are some how or other intimately connected, and are either composed of different proportions of the same ingredients, or the

one enters into the composition of the other. One of the fast theories of this kind (for the opinion Scheele's of Stahl has been already discussed) was formed by Mrtheory of Scheele *, one of the most extraordinary men and great light and est philosophers that ever existed. Without the affist * in his ance of education or of wealth, his genins burft forth realijem with altonishing lustre; and at an age when most phi-Fire losophers are only rising into notice, he had finished a career of difcoveries which have no parallel in the annals of chemistry. Whoever wishes to behold ingenuity combined with fimplicity, whoever wishes to see the inexhaustible resources of chemical analysis, whoever wishes tor a model in chemical refearches-has only to peruse and to study the works of Scheele (T). After a vast number of experiments, conducted with astonishing ingenuity, he concluded, that caloric was composed of a certain quantity of oxygen combined with phlogiston; that radiant heat, a fubitance which he supposed capable of being propagated in straight lines like light, and not capable of combining with air, was composed of oxygen united with a greater quantity of phlogiston, and light of oxygen united with a still greater quantity. He supposed, too, that the difference between the rays depended upon the quantity of phlogiston: the red, according to him, contained the leaft; the violet, the minous altogether; but we have no reason to suppose most phlogiston. By phlogiston Mr Scheele seems to

(R) Particularly by Dr Parr, who is faid to be the author of a paper on this subject, published in the Exeter Memoirs.

(s) A gentleman, to whom we mentioned this objection, observed, that in the case of bodies long exposed to heat, the light, which appears to proceed from them, might, in fact, be extricated from the atmosphere by the caloric communicated to it from the heated body. This thought is new and ingenious, and might eafily be put to the test of experiment. Some of the facts mentioned in the text are rather hostile to it; but should it prove

330 Objections to which is liable.

well founded, it would go far to remove most of the difficulties in which the theory of light is at prefent involved. (T) This Newton of chemistry died in 1786, at the age of 44. His moral character, according to Mr Erhart and others, who were the companions of his youth, and Meffrs Gadolin, Efpling, and those who knew him in his latter days, was irreproachable and praise worthy. His outward appearance was not expressive of the great mind which lay concealed as it were under a veil. He feldom joined in the usual conversations and amusements of fociety, having as little leifure as inclination to do fo; for what little time he had to spare from the hurry of his prof. ffion (an apothecary), was constantly filled up in the profecution of experiments. It was only when he received visits from his friends, with whom he could converse upon his favourite science, that he indulged himself in a little relaxation. For fuch friends he had a fincere affection, as he had also for those that lived at a distance, and even for such as were not personally known to him. He kept up a regular correspondence with Messrs Erhart, Meyer, Kirwan, Crell, and several other chemists. See Crell's Life of Scheele.

have meant hydrogen. It is needless therefore to examine his theory, as it is now known that the combination of hydrogen and oxygen forms not caloric but water (v) The whole fabric therefore has tumbled to the ground; but the importance of the materials will always be admired, and the ruins of the structure shall remain eternal monuments of the genius of the builder.

Mr de Luc, fo well known for his important meteorological labours, has advanced another theory *. According to him, light is a body which moves constantly la in straight lines, with such rapidity that its gravitation towards other substances bears no sensible proportion to its motion. Light has the property of combining with another unknown fubflance, and the compound formed is caloric, which poslesses very different properties from light Caloric is constantly describing helicoidal curves round an axis, which accounts for the flowness of its ap. parent motion. Light produces or increases heat, partly by increasing the expansive power of caloric, and partly by combining with the unknown fubstance, and forming new caloric; caloric, on the other hand, is always decomposed when bodies become luminous. theory is certainly ingenious, and would remove many of the difficulties which we at prefent labour under in attempting to explain the phenomena of caloric and light It is, however, liable to other difficulties, which could not be eafily furmounted. But it is needless to examine these, as the theory itself is supported by no evidence whatever, and cannot therefore be admitted.

Another theory has been advanced by the late Dr Hutton of Edinburgh (1); a man of undoubted genius,

but of rather too speculative a turn of mind, and who sometimes involved himself in difficulties from his very ingenuity. All his writings display evident marks of the profound philosopher: they contain much instruction; and even his mistakes are not without their use: but unfortunately his manner is so peculiar, that it is scarcely more difficult to procure the secrets of science from Nature herself, than to dig them from the writings of this philosopher. He supposes that there are two kinds of matter, gravitating matter and light; the last of which wants gravity, and consequently neither possesses magnitude (w) nor momentum. Light has the power of being fixed in bodies; and then it becomes either caloric or phlogiston, which differs in some particulars from caloric, but in what, the Doctor does not precisely tell us.

Part of this theory we have examined already when we attempted to prove that light and caloric were different substances. The other part of the theory seems to involve a contradiction; for how could light become fixed in a body, unless it were attracted by it? and if light possesses attraction, it surely cannot be destitute of gravity; for what is gravity but attraction (x)?

Thus, notwithstanding the ingenuity of the philosophers who have attempted to investigate this part of chemistry, the connection between light and caloric is still unknown. We must content ourselves, therefore, with considering them at present as distinct substances, and leave the solution of the many difficulties which at present perplex us to the more happy labours of future enquirers.

PART II. OF COMPOUND BODIES.

TO those bodies, which are composed of two simple substances combined together, for want of a better name we have given the appellation of compound bodies. They may be reduced under five classes:

- 1. Water;
- 2. Alcohol;
- 3. Oils; 4. Alkalies;
- 5. Acids.

These shall be the subject of the five following chapters; and we shall finish this part of the article with some observations on Affinity.

CHAP. I. Of WATER.

WATER is a well-known liquid, found in abundance in every part of the world, and abfolutely necessary for the existence of animals and vegetables.

When pure, in which state it can be obtained only

by distillation, it is transparent, and destitute of colour, taste, and smell.

A cubic foot of water, at the temperature of 55°, Weight of weighs, according to the experiments of Professor Rowater. bison of Edinburgh (see Specific Gravity, Encycl.), 998,74 avoirdupois ounces, of 437,5 grains troy each, or only 1,26 ounces less than 1000 avoirdupois ounces; so that rain water, at the same temperature, will weigh pretty nearly 1000 ounces. The specific gravity of water is always supposed = 1,000, and it is made the measure of the specific gravity of every other body.

When water is cooled down to 32°, it assumes the form of iee. If this process goes on very slowly, the ice assumes the form of crystalline needles, crossing each other at angles either of 60° or 120°, as Mr de Mairan has remarked; and it has been often observed in large crystals of determinate sigures. Ice, while kept at a temperature considerably below 32, is very hard, and may be pounded into the finest dust. It is elastic. Its specific gravity is less than that of water.

When

(v) This candid philosopher afterwards acknowledged, that the proofs for the composition of water were complete; but we do not know exactly how he attempted to reconcile his theory of heat with the belief that water was composed of oxygen and hydrogen; two opinions which are certainly incompatible.

(v) See his differtations on different subjects of natural philosophy.

(w) Indeed Dr Hutton refused this property to gravitating matter also; following, in this particular, the theory of the celebrated Boscovich.

(x) We hope not to be accused of disputing merely about the meaning of a word, till what is said on this subject in the chapter of the present article, which treats of Affinity, has been examined.

335: Ice.

Water. 336 Steam.

When water is heated to the temperature of 212°, it boils, and is gradually converted into steam. Steam is an invisible fluid like air, but of a less specific gravity. It occupies about 1200 times the space that water does. Its elasticity is so great, that it produces the most violent explosions when confined. It is upon this principle that the steam-engine has been constructed. See STEAM and STEAM-Engine, Encycl.

Boiling point of water

338

Impregna-

The phenomena of boiling are owing entirely to the rapid formation of fleam at the bottom of the veffel. The boiling point of water varies according to the preffure of the atmosphere. In a vacuum water boils at 90°; and when water is confined in Papin's digefter, it may be almost heated red hot without boiling. The mixture of various falts with water affect its boiling rious falts. point confiderably. Mr Achard made a number of experiments on that subject; the result of which may be feen in the following tables ‡.

Water compref-Lible.

Water was once supposed to be incompressible; but the contrary has been demonstrated by Mr Canton. The Abbé Mongez made a number of experiments, long after that philosopher, on the same subject, and obtained fimilar refults.

Opinion about its mature.

Water was believed by the ancients to be one of the four elements of which every other body is composed; and, according to Hippocrates, it was the substance which nourishes and supports plants and animals. That water was an unchangeable element continued to be believed till the time of Van Helmont, who made

plants grow for a long time in pure water: From Water which experiment it was concluded, that water was convertible into all the substances found in vegetables .-Mr Boyle having digetted pure water in a glass veffel hermetically fealed for above a year, obtained a quantity of earthy scales; and concluded, in consequence, that he had converted it partly into an earth * He * Shaw obtained the same earth by distilling water in a tall glass Boyle, iii vessel over a slow fire t. Margraf repeated the experi 417. ment with the fame refult, and accordingly drew the 267. fame conclusion. But the opinion of these philosophers was never very generally received. The last person who embraced it was probably Mr Waselton, who published his experiments on the subject in the Journal de Physique for 1780. Mr Lavoisier had proved, as early as 1773, that the glass vessels in which the distillation was performed loft a weight exactly equal to the earth obtained Hence it follows irrefiftibly, that the appearance of the earth, which was filica, proceeded from the decomposition of the vessels; for glass contains a large proportion of filica. It has been fince shown by Dr Priestley, that water always decomposes glass when applied to its surface for a long time in a high temperature.

We have formerly mentioned, that water is com. History posed of oxygen and hydrogen. This great discovery the dife has contributed more perhaps than any other to the advery fi vancement of the science of chemistry, by furnishing a tion key for the explanation of a prodigious number of phenomena. The evidence, therefore, on which it rests, and the objections which have been made to it, deserve

to be examined with peculiar attention.

The first person probably who attempted to discover what was produced by burning hydrogen gas was Scheele. He concluded, that during the combustion oxygen and hydrogen combined, and that the product

In 1776 Macquer, affifted by Sigaud de la Fond, set fire to a bottle full of hydrogen gas, and placed a faucer above the flame, in order to fee whether any fuliginous smoke would be produced. The faucer remained perfectly clean; but it was moistened with drops of a clear liquid, which they found to be pure water ;.

Next year Bucquet and Lavoisier exploded oxygen Distination and hydrogen gas, and made an attempt to discover flammable what was the product; about the nature of which they had formed different conjectures. Bucquet had suppofed that it would be carbonic acid gas; Lavoisier, on the contrary, suspected that it would be sulphuric or fulphurous acid. What the product was they did not discover; but they proved that no carbonic acid gas was formed, and confequently that Mr Bucquet's hypothelis was ill founded !.

In the beginning of the year 1781, Mr Warltire, at Par. 17 the request of Dr Priestley, fired a mixture of these 470. two gales contained in a copper veffel; and observed, that after the experiment the weight of the whole was diminished. Dr Priestley had previously, in the presence of Mr Warltire, performed the same experiment in a glass vessel. This vessel became moist in the infide, and was covered with a footy fubstance f, which & Priefle, Dr Priestley afterwards supposed to be a part of the v. 395. mercury used in filling the vessel *.

In the summer of 1781, Mr Henry Cavendish, who Trans. had been informed of the experiments of Priestley and lxxiv. 33

Warltire, set fire to 500,000 grain measures of hydrogen gas, mixed with about 21 times that quantity of common air. By this process he obtained 135 grains of pure water. He also exploded 19,500 grain meafures of oxygen gas with 37,000 of hydrogen gas, and obtained 30 grains of water, containing in it a little nitric acid. From these experiments he concluded that water was a compound. -Mr Cavendish must therefore be confidered as the real discoverer of the composition of water. He was the first who ascertained that water was produced by firing oxygen and hydrogen gas, and the first that drew the proper conclusion from that fact. Mr Watt, indeed, had also drawn the proper conclufion from the experiments of Dr Priestley and Mr Warltire, and had even performed a number of experiments himself to ascertain the fact, before Mr Cavendish had communicated his; but he had been deterred from publishing his theory by some experiments of Dr Priestley, which appeared contrary to it +. He has therefore a claim to the merit of the discovery; a claim, however, which does not affect Mr Cavendish, who knew nothing of the theory and experiments of that ingenious philosopher.

Meanwhile, in the winter 1781-2, Mr Lavoisier, who had suspected, that when oxygen and hydrogen gas were exploded, fulphuric or fulphurous acid was produced, made an experiment in order to ascertain the fact, at which Mr Gingembre affisted. They filled a bottle, capable of holding fix pints (French), with hydrogen gas, to which they fet fire, and then corked the bottle, after pouring into it 2 oz. (French) of lime water. Through the cork there passed a copper tube, by means of which a stream of oxygen gas was introduced to support the slame. Though this experiment was repeated three times, and instead of lime water a weak solution of alkali and pure water were substituted, they could not observe any product whatever ‡. This rear. 1781, sult aftonished Mr Lavoisier exceedingly: he resolved, therefore, to repeat the experiment on a larger scale, and if possible with more accuracy. By means of pipes furnished with stop-cocks, he put it in his power to supply both gases as they should be wanted, that he might be enabled to continue the burning as long as he thought

> The experiment was made by Lavoisier and la Place on the 24th of June 1783, in the presence of Messrs le Roi, Vandermonde, several other academicians, and Sir Charles Blagden, who informed them that Mr Cavendish had already performed it, and that he had obtained water *. They continued the inflammation till all their flock of gases was wasted, and obtained about 295 grains of water, which, after the most rigid examination, appeared to be perfectly pure. From this experiment Lavoisier concluded, that water was composed of oxygen and hydrogen. Mr Monge soon after performed the same experiment, and obtained a similar refult: and it was foon after repeated again by Lavoisier and Meusnier on a scale sufficiently large to put the fact beyond doubt *.

SUPPL. VOL. I. Part I.

The proofs that water is a compound are of two Water. kinds; it has been actually composed, and it has been decomposed.

With regard to the composition of water, we shall re-the compolate the celebrated experiment made by Lavoisier and stion of Meusnier in the month of February 1785, in the presence water. of a numerous deputation from the academy of sciences, Ex; eriment and so many other spectators, that it may be consider of Lavoisier ed as having been performed in public. Every pré-and Meuf-caution was taken to enfure fuccess. The gases had nier. been prepared with care, and held for some time over a folution of potafs, in order to deprive them of any acidity which they might accidentally contain; and before entering into the glass globe where they were to be burnt, they were made to pass over newly calcined potass, to deprive them of the water which they might happen to retain in folution. The hydrogen gas had been obtained by passing steam through iron at a white heat; the oxygen gas was procured from the red oxyd of mercury. The combustion took place in a large glass globe, into which the gases were admitted by means of tubes furnished with stop-cocks; and the most ingenious contrivances were employed to ascertain exactly the quantities of each which were confumed (Y). The whole machine is described at large by Mr Mensnier in the Memoires of the Academy of Sciences for

The quantities of gas employed, after deducting the 432 grains of refiduum which were not confumed, were 2794,76 grains of oxygen gas, and 471,125 of hydrogen gas. After taking from these 32,25 grains, = the humidity of which the oxygen gas was deprived by the calcined potals, and 44,25 grains, = the weight which the hydrogen lost by the same process, there remains

altogether 3188,4 grains of gas.

The quantity of water obtained amounted to 3219 grains; the specific gravity of which was to distilled water as 1,0051 to 1. This quantity was 30 grains more than the gas employed. The difference, no doubt, was owing to a small error in estimating the weight of the gafes; which indeed it is extremely difficult to avoid, as the weight is altered by the smallest difference of temperature. This water had a flight fmell, and a talte fensibly acid; it reddened slightly blue paper, and effervesced with the carbonat of potals. 1152 grains of that water being faturated with potafs, and evaporated to dryness, left 20 grains of a falt which melted on the fire like nitre. It follows from this experiment, that the quantity of acid contained in the whole water would not have been quite sufficient to have formed 56 grains of nitre.

The residuum weighed, as has been already observed, 432 grains; its volume was equal to 444 grains of oxygen gas; it was diminished by nitrous gas (z) precisely as gas would be which contained 0,24 parts of oxygen; it rendered lime water fornewhat turbid, which indicated the prefence of carbonic acid gas.

From the comparison of the weights, and volumes of the gases consumed, it was concluded that water con-00

(v) A variety of inftruments have been invented by the French chemists for that purpose. These inftruments they have denominated Gazometers.

(%) This gas shall be afterwards described. It has the property of absorbing almost instantaneously the oxygen gas with which it comes into contact. It is therefore often used, in order to discover how much oxygen gas exists in any mixture.

Water. fifts of 0,85 parts, by weight, of oxygen, and 0,15 of hydrogen.

344 This experiment was foon after repeated by Mr le Experiment of Le Fevre Fevre de Gineau upon a still larger scale, and in the prede Gineau. fence of a great number of spectators. It continued for no less than 12 days, and was performed with the most rigorous exactness of which experiments of that nature

* Journ. de will admit *.

Phys. 1788, The oxygen gas employed, which had been procured from the black oxyd of manganese, occupied the space of 35085,1 cubic inches, and weighed 18298,5 grains.

The hydrogen gas was obtained by diffolving iron in diluted sulphuric acid. Its volume was 7496,7 cubic inches, and its weight 4756,3 grains. The two gases, therefore, amounted to -From which taking the refiduum after com-

2831,0 buftion, which amounted to

There remains for the quantity confumed, - 20223,8 The water found in the glass globe after the combustion amounted to - -20139,0 And there were carried off by the refiduum, - 54,0

In all, Which is just 30 grains less than the weight of the gases which disappeared, or 37 part of their weight. This difference arose from the same difficulties which attended the experiment of Lavoisier. As the errors are on different fides, we are warranted to conclude that this was the case, and that it was not owing to any real difference between the gases and the product.

The water was examined in the presence of Messes Lavoisier, le Roi, Monge, Berthollet, Bayen, and Pelletier. Its specific gravity was to that of distilled water as 1,001025 to 1. It contained no fulphuric nor muriatic acids; yet it had an acid taste, and converted vegetable blues to a red. 6606 grains of it required for faturation 36 grains of carbonat of potals, and furnished by evaporation 26,5 grains of crystals of nitre. The whole water, therefore, would have required 109,7 grains of carbonat of potals for faturation.

This water affected lime water a little; and it was found, that the relidium of the gas contained some carbonic acid gas. This residuum formed a nineteenth part of the volume of the two gases employed, and an eighth of their weight. It contained 462 grains of carbonic acid gas, or about 1 part; the rest was azotic

gas, with about To of oxygen. This experiment gave the proportions of oxygen and

hydrogen in water as follows:

Oxygen, ,848 Hydrogen, ,152 1,000

This is so near the determination of Mr Lavoisier, that it must be considered as a very strong consirmation of it.

In the year 1790, another fimilar experiment was performed by Seguin, Fourcroy, and Vauquelin, in the presence of a number of commissioners appointed by the academy of sciences. Every precaution was taken to afcertain the quantity of gas employed with the utmost exactness, and to exclude all atmospherical air as completely as possible.

The hydrogen gas was procured by diffolving zinc Water. in fulphuric acid diluted with 7 parts of water. The oxygen gas was obtained by distilling oxy-muriat of

The quantity of hydrogen gas employed amounted to 862,178 grains troy. The quantity of oxygen gas amounted to 13475,198 cubic inches (French). Its purity was fuch, that it contained three cubic inches of azotic gas in the 100. The whole gas, therefore, contained 404,256 cubic inches. There were likewise in the glass vessel in which the combustion took place 15 cubic inches (French) of atmospheric air, which confifted of 11 cubic inches of azotic and four of oxygen gas. So that the whole oxygen gas employed amounted to 13074,942 cubic inches; and it contained befides 415,256 cubic inches of azotic gas. They afcertained by experiment, that a cubic inch of this oxygen gas, thus diluted with Too of azot, weighed ,4040 of a grain troy. Now, according to the experiments of Lavoisier, a cubic inch (French) of azotic gas weighs only ,3646 of a grain troy. Consequently the weight of pure oxygen gas is greater than ,4040; and by calculation they shewed it to amount to ,4051 of a grain troy. The weight of the whole oxygen gas employed, therefore, was 5296,659 grains troy; and that of the azotic gas mixed with it 151,402 grains troy.

The combustion continued 185 hours; and during all that time our philosophers never quitted the laboratory. The flame was exceedingly fmall, and the heat produced by no means great. This was owing to the very fmall stream of hydrogen, which was constantly

flowing into the veffel.

The water obtained amounted to 5943,798 grains troy, or 12 oz. 7 dwts. and 15,798 grains. It exhibited no mark of acidity, and appeared in every respect to be pure water. Its specific gravity was to that of distilled water as 18671 to 18670; or nearly as 1,000053

The refiduum of gas in the vessel after combustion amounted to 987 cubic inches (French); and on being examined, was found to confift of the following

quantities of gales:

Azotic gas, - - - - 467 cubic inches. Carbonic acid gas, - - -Oxygen gas, - - -Hydrogen gas, - -Total, - 987

The Weight of which is as follows: Azotic gas, - - - - 170,258 gr. troy. Carbonic acid gas, - - - 23,306 Oxygen gas, - - - 188,371 Hydrogen gas, - - - 0,530

Total, - 382,465

Now the weight of the whole gases employed was, - - - -6310,239 gr. troy. That of the water obtained, and of the refiduum, - - - 6326,263

16,024 grains Or, - - - - - - - more than had been employed. This small quantity

and Vau-

quelin.

Water. must have been owing to common air remaining in the tubes, and other parts of the apparatus, in spite of all the precautions that were taken to prevent it; if it did not rather proceed from unavoidable errors in their valuations. The quantity of azotic gas introduced was 151,178 The quantity found in the refiduum was 170,258

> There was therefore a furplus of - - - 19,080 gr. As fufficient precautions had been taken to prevent the introduction of carbonic acid gas, the quantity found in the refiduum must have been formed during the process. There must therefore have been a finall quantity of carbon introduced. Now zinc often contains carbon, and hydrogen has the property of diffolving carbon: probably, then, the carbon was introduced in this manner. The carbonic acid found in the refiduum amounted to 23.306 grains, which, according to Lavoifier's calculation, is composed of 8,958 grains of carbon, and 14,348 grains of oxygen.

Substracting these 8,958 grains of carbon, and the 530 of a grain of hydrogen, which remained in the veffel, from the total of hydrogen introduced, there will remain 852,690 grains for the hydrogen that disap-

peared.

225.

Substracting the 14,348 grains of oxygen which entered into the composition of the carbonic acid, and the refiduum of oxygen, which amounted to 188,371 grains, the quantity of oxygen that disappeared will amount to 5093,940 grains.

Hydrogen that disappeared, - 852,690 gr. troy. 5093,940 Oxygen, -

Total, - 5946,630 Quantity of water obtained, - 5943,798

Which is less than the gases con-

fumed by - - - - -2,832 grains *. Such are the principal experiments upon which the opinion is founded that water is a compound. Let us examine them, and fee whether they are sufficient to establish that opinion. The circumstances which chiefly claim our attention, and which have been chiefly in-

tifted on, are thefe: 1. The whole of the gales was not confumed.

2. In the refiduum were found feveral substances polition of which were not introduced, and which must therefore water exa- have been formed during the combustion.

3. The water obtained was feldom perfectly pure.

It generally contained some nitric acid.

4. As only part of the gases were consumed, and as all gases contain water in them, might not the gas other substances found in the refiduum? and might not the water obtained have been merely what was former ly dissolved in the gases, and which had been precipitated during the experiment?

That the whole of the gases was not consumed will not surprise us, if we recollect that it is impossible for that to take place, allowing them to be perfectly pure, except they be mixed in precifely the proper propor-

tions; and not even then, except every particle of them Water. could be raifed to the proper temperature. Now how can this be done in experiments of that nature?

But how is it possible to procure a large quantity of gas completely pure? And supposing it were possible, how can every particle of atmospheric air be excluded? In the last experiment, notwithstanding every precaution, 15 cubic inches (French) were admitted; and there is reason to believe from the results, that the quantity was even confiderably greater than this. But if any atmospheric air be admitted, there mult be a refiduum of azotic gas.

In the first experiment, it had been previously aforttained that the oxygen gas employed contained 12th of azotic, or about 233,05 grains; and the refiduum contained at must 329, 1 grains, or 96,05 grains more than what had for certain pre-existed in the gases.

In the second experiment, the azot in the refiduum amounted at most to 1/8th of the oxygen gas employed. But the oxygen was procured from the black oxyd of manganese, which always yields a quantity of azot as well as of carbonic acid. It has been ascertained, that the azot, mixed with oxygen gas procured in that manner, often exceeds 18th.

In the third experiment, the azotic gas found in the refiduum amounted to 170,258 grains; and the quantity contained in the gases before combustion amounted to 151.178 grains: the furplus, therefore, amounted

to 19,08 grains.

Now, is it not much more probable that these inconfiderable quantities of azot, which in the last experiment amounted to no more than 13 part by weight of the whole gas employed, pre-existed in the gases before the combustion began, though their extreme minuteness prevented them from being discovered, than that they were formed during the experiment? a supposition which is directly contradicted by a great number of well ascertained facts.

As to the carbonic acid gas, which in the fecond experiment amounted to the gafes employed, it was evidently derived from the manganese, which almost constantly contains it. And when carbonic acid is once mixed with oxygen, it is difficult to separate it by means of lime water, except a large quantity be used, as Mr Cavendish has well observed. The reason is, that oxygen gas has the property of diffolying carbonic acid, as Mr Welter has remarked †. Mr le Fevre de Gi + Ann. de neau ascertained by experiment, that 1870 cubic inches Chim. iii. of oxygen gas, which did not affect lime water, loft be 91. tween 18th and 10th of its weight when washed in

milk of lime (B).

In a fecond experiment, he previously washed the which disappeared have been employed in forming the two gases in milk of lime, and the residuum after combustion contained no carbonic acid gas. In a third experiment he washed only the oxygen, and obtained products equally free from carbonic acid. It is certain, then, that the carbonic acid is but an accidental mixture. As to the carbonic acid of the third experiment above related, which amounted only to the gases employed, the source of it has been already point-

48.

As to the nitric acid, the quantity of nitre obtained in Mr Lavoisier's experiment was 56 grains; which, according to Mr Kirwan's calculation, contain 30,156 grains of nitric acid; a quantity confiderably less than 100th part of the gases which disappeared. In the second experiment, the nitre obtained amounted to 80,7 grains; which, according to Kirwan, contain 43,456 grains of nitric acid, or less than 450th part of the gases confumed. Now, as nitric acid is composed of oxygen and azot, both of which were present in the vessel, it is easy to see how it was produced. And that its production is merely accidental, and not necessary, is evident from the last experiment, in which no nitric acid was formed. It has been afcertained, indeed, that the formation of this acid during these experiments is quite arbitrary. It never is formed when the combustion goes on fo flowly as to produce but little heat, as Seguin has ascertained *; because oxygen and azot do not combine except at a high temperature. Nor is it formed even at a high temperature, as Mr Cavendish has proved +, except there be a deficiency of hydrogen; because hydrogen has a stronger affinity for oxygen than azot has.

The quantity of water obtained in the first experiment was just 30 grains more than the weight of the gases which had disappeared: the water obtained in the fecond was precifely 30 grains less than the gases confumed: and in the third experiment, the difference was only 16 grains. The quantities of gas operated upon were large; in all of the experiments feveral thoufand grains, and in one of them above 20 thousand. Now, how is it possible that the water produced should correspond so exactly with the gases confumed (for the differences are so small as not to merit any attention), unless the water had been formed by the combination of these gases?

Dr Priestley, however, who made a great many experiments on this subject, drew from them a very different conclusion; and thought he had proved, that during the combustion the two gases combined, and that the combination was nitric acid. This theory was adopted, or rather it was fuggested, by Mr Keir, who has supported it with a great deal of ingenuity +.

Let us examine these experiments of Dr Priestley *, and fee whether they warrant the conclusions he has drawn from them. The gases were exploded in vessels of copper. He found that the quantity of water obtained was always less than that of the gases which he had used. He obtained also a considerable quantity of nitric acid. In the experiment made on the largest quantity of the gases, and from which he draws his conclusions, the quantity of liquid obtained amounted to 442 grains. This liquid was examined by Mr Keir.

It was of a green colour, 72 grains of brown oxyd of Water. copper were deposited in it, and it contained a solution of nitrat of copper (copper combined with nitric acid). Mr Keir analysed this liquor: It consisted of pure water and nitrat of copper; and Mr Keir concluded that the nitric acid formed amounted to 10 of the oxygen gas emploged. Mr Berthollet, however, has shewn, that it could not have amounted to more than 1 part f. f Ann. de Let us suppose, however, that it amounted to 1. A Chim. iii. quantity of oxygen and hydrogen gas has ditappeared: 86. What has become of them? They have combined, fays Dr Priestley, and formed nitric acid. This nitric acid is only 1 of their weight: Dr Priestley supposes, however, that it contains the whole oxygen and hydrogen that existed in these gases, and that all the rest of the weight of these gases was owing to a quantity of water which they had held in folution. Oxygen gas, then, (for we shall neglect the hydrogen, which Dr Priestley was not able to bring into view at all) is composed of one part of oxygen and 19 of water. Where is the proof of this? Dr Priestley informs us, that he ascertained by experiment that half the weight of carbonic acid gas was pure water. Supposing the experiment accurate (c), what can be concluded from it? Surely to bring it forward in proof, that oxygen gasconfifts of 10 parts, or almost wholly of water, is downright trifling. It is impossible, therefore, from Dr Priestley's experiments, allowing his suppositions and conjectures their utmost force, to account for the disappearing of the two gases, or the appearance of the water, without admitting that this liquid was actually composed of oxygen and hydrogen. If we add to this, that no oxygen gas has hitherto (as far as we know at least) been procured absolutely free from some admixture of azot, and that his oxygen was always procured either from red oxyd of lead, or from black oxyd of manganese, or red oxyd of mercury, all of which substances yield a considerable proportion of azot; that in one experiment, in which he observes that his oxygen was very pure, as it had been obtained from red oxyd of mercury, Mr Berthollet (D) ascertained, by actually making the experiment, that part of the very same oxyd which Dr Priestley had employed yielded a gas, 1 d of which was azot*; if we add, that it has been proved beyond * Ann. de the possibility of doubt, and to Dr Priestley's own fa. Chim. iii. tisfaction, that nitric acid is composed of oxygen and 94. azot-we shall find it no difficult matter to explain the origin of that acid in Dr Prieftley's experiments: and if we recollect that in Seguin's experiment, upon a much larger scale indeed than Dr Priestley's, no nitric acid at all was formed, it will be impossible for us to believe for a moment that the compound formed by

oxygen and hydrogen is nitric acid. Thus Dr Priest-

(c). He informs us, that the carbonat of barytes does not yield its carbonic acid by means of heat (this Dr Hope has shewn to be a mistake); but that, when the vapours of water are passed over it, the gas is disengaged: and he determines, by the water missing, how much has combined with the gas. According to him, 60 grains of water enter into the composition of 147 grains of gas. But, besides assigning too small a weight to the gas, he forgot that its temperature was high, and that therefore it was capable of combining with much more water than in its usual state: nor did he ascertain whether more of this water was deposited on the vessels; and yet, by neglecting this precaution, Morveau has shewn, that Mr Kirwan, in a similar experiment, obtained a result nine times greater than it ought to have been. Encycl. Method. Chim. art. Air.

(D) Mr Berthollet had supplied Dr Priestley with the oxyd. He had received two ounces of it from Mr Le

Blane, one of which he fent to Dr Priestley, and the other he reserved.

+ Keir's Dictionary, art. Nitrous Asid. * Pbil. Trans.

1788.

ley's experiments rather confirm than deftroy the theory of the composition of water. We obtain from them, however, one curious piece of information, that the presence of copper increases the quantity of nitric acid formed. This curious fact, with a variety of others of a similar nature, will perhaps afterwards claim our attention; but at present we must consider another theory which this phenomenon suggested, and which was first proposed, we believe, by Mr de la Metherie (E).

Had the French chemists, it has been said, employed copper veffels in their experiments, they would have obtained three times the quantity of nitric acid. This acid, therefore, mult in their experiments have been deeomposed, after having been formed, for want of a base to combine with; and the azot which appeared in the refiduum was owing to this decomposition. Hydrogen and oxygen, therefore, do not form water, but azot (F). Let us examine the experiment of Mr Le Fevre by this theory, as the quantity of azot was accurately afcertained. The nitric acid obtained amounted to 43,456 grains; three times that quantity is 130,368 grains, into which 23054 grains of gas were converted; which is impossible. Or even supposing that the decomposition had been going on during the whole experiment, which is directly contrary to Dr Priestley's experiments, and which there is no reason whatever to suppole, but every reason against-still the whole azot amounted only to the quantity of gas employed, allowing this gas to have contained no azot, which was evidently not the cafe. It appears, then, that this hypothefis, even if it could be admitted, would be totally inadequate to account for the phenomena. But if we were to examine it by Mr Seguin's experiment, its abfurdity would be still more glaring. In that experiment the azotic gas amounted to only 19 grains, and the quantity of gas which disappeared was 5946 grains: so that were the hypothesis true, oxygen and hydrogen gas would confift of one part of oxygen and hydrogen and 312 parts of water; a supposition so enormously absurd, that it is impossible for any person even to advance it.

It is impossible, therefore, for the phenomena which attend the combustion of oxygen and hydrogen gas to be accounted for in any way confistent with common sense, except we suppose that water is formed.

But the experiments above related, conclusive as they appear, are not the only ones by which this important fact has been ascertained. Messrs Van Troostwyk and Dieman, affisted by Mr Cuthbertson, filled a small glass tube, the of an inch in diameter and 12 inches long, with diffilled water. One end of this tube was sealed hermetically; but, at the fame time, a fmall gold wire had been passed through it. Another wire passed thro' the open end of the tube, and could be fixed at greater

or smaller distances from the first wire. By means of Water. these wires, they made a great number of electrical explofions pals through the water. Bubbles of air appeared at every explosion, and collected at the top of the tube. When electric sparks were passed through this air, it exploded and disappeared almost completely. It must therefore have confisted of a mixture of oxygen and hydrogen gas, and this gas must have been formed by the decomposition of the water: for they had taken care to deprive the water before hand of all its air, and they used every precaution to prevent the access of atmospherical air; and, besides, the quantity of gas produced did not diminish, but rather increased, by continuing to operate a number of times upon the fame water, which could not have been the case had it been merely air diffolved in water: nor would atmospherical air have exploded and left only a very small residuum, not more than tothe part. They had taken care also to prove that the electric spark did not contribute to form hydrogen gas; for on passing it through sulphuric and nitric acids, the product was not hydrogen, but oxygen gas †.

These experiments have been since repeated by Dr Pearson, assisted by Mr Cuthbertson. He produced, by means of electricity, quantities of gas from water, amounting to 56,5488 cubes of Toth of an inch each; on nitrous gas being added to which, it suffered a diminution of bulk, and nitrous acid appeared to have been formed: It must therefore have contained oxygen gas. When oxygen gas was added to the remainder, and an electric spark passed through it, a diminution took place precifely as when oxygen and hydrogen gas are mixed: It must therefore have contained hydrogen. When an electric spark was passed through the gas thus produced from water, the gas disappeared, being no

doubt converted into water *.

Such are the proofs by which the compound nature fon's fourof water is afcertained; and we do not believe that any physical fact whatever can be produced which is sup-

ported by more complete evidence. But what becomes of the caloric which was previoufly combined with these gases? It passes through the vessel and is lost, and its weight is too inconsiderable to make any fensible variation in the quantity of the product. If we were to judge from analogy, we would conclude, that the oxygen and hydrogen, while in the state of gas, are probably somewhat lighter than after they are condensed into water; but the difference, if it exists, can scarcely be sensible.

Water is capable of combining with a vast number of Combinafubstances: all bodies, indeed, which are foluble in wa-tion and ter form a chemical union with it.

Its affinity for other bodies is doubtless various, the? water. we have no method of afcertaining this difference, ex-

Phys. xxxv.

(F) This, as has been formerly explained, was the original opinion of Dr Pricftley; to which, though he does not explain himself fully, he evidently still adheres. There is then no difference between his theory and this, except

what relates to the decomposition of the nitric acid.

⁽E) Another favourite theory of La Metherie was, that gases themselves are destitute of gravity, and that they owe their whole weight to the water with which they are combined: that during combultion the water of the two gales is depolited; and that the gales themselves escape through the vessel and are lost. He complains bitterly that this theory had never been noticed by his antagonists; as if it were necessary to refute a hypothens which is not supported by any proof whatever, and as if it had not been proved that oxygen increases the weight of metals, and consequently possesses gravity.

Alcohol.

cept in those bodies which have no affinity, or but a very fmall affinity, for each other; and it is only in a few even of these that this difference can be ascertained. If muriat of barytes be poured into lime water, the lime is precipitated, owing, no doubt, to the fuperior affinity of the muriat for water. Several very curious inflances of the affinity of different falts for wa ter have been mentioned by Mr Quatremere Dijonval. When the folutions of nitrat of lime and nitrat of magnefia in water are mixed together, the nitrat of magnefia is precipitated. Muriat of magnefia is also precipitated by muriat of lime, and fulphat of magnefia by fulphat of lime: fo that it would feem that the falts which have magnefa for their balis, have a lefs affinity # Journ. de for water than those whose basis is lime !.

Pbyf. xvii.

Water has the property of diffolving oxygen gas. If a quantity of common air be confined for tome time above water, the whole of the oxygen is absorbed, and nothing but the azotic gas remains. This fact was first observed by Mr Scheele.

CHAP. II. Of ALCOHOL.

349 Difcovery

* Lib. ii.

n. 77. + De Mo-

rib. Germ.

ch. xxiii.

Wine has been known from the earliest ages. The Scriptures inform us, that Noah planted a vineyard and drank wine; and the heathen writers are unanimous in ascribing the invention of this liquor to their earliest kings and heroes. Beer, too, feems to have been dilcovered at a very remote period. It was in common use in Egypt in the time of Herodorus *. Tacitus informs us, that it was the drink of the Germans +. Whether the ancients had any method of procuring ardent spirits from these or any other liquors, does not appear. The Greeks and Romans feem to have been ignorant of ardent spirits altogether, at least we can d scover no traces of any fuch liquor in their writings. But among the northern nations of Europe, intoxicating liquors were in use from the earliest ages. Whether these liquors resembled the beer of the Germans, we do not know. It is certain, at least, that the method of procuring ardent spirits by distillation was known in the dark ages; and it is more than probable that it was practited in the north of Europe much earlier. They are mentioned expressly by Thaddaus, Villanovanus, and Lul-

art. ii. 4. 350 Method of procuring it.

\$ Berg. 4th. ly \$.

Ardent fpirits, fuch as brandy, for instance, rum, and art. ii. 4.

Ardent spirits, fuch as brandy, for instance, rum, and whisky, consist almost entirely of three ingredients, water, alcohol or spirit of wine, to which they owe their strength, and a small quantity of a peculiar oil, to which

they owe their flavour.

The alcohol may be separated from the water by the following process. Into the whisky or other ardent spirit a quantity of potass is to be put, which has just immediately before been exposed for about half an hour in a crucible to a red heat, in order to deprive it of moisture. Potass in this state has a strong attraction for water; it accordingly combines with the water of the spirit, and the folition of potass thus formed finks to the bottom of the veffel, and the alcohol, which is lighter, swims over it, and may eafily be decanted off; or, what is perhaps better, the folution of potals may be drawn off from below it by means of a stop cock placed at the bottom of the vessel. It is impossible to fix the quantity of potass which ought to be used, because that must depend en- capable of containing about 15 pints (French). Into

sequence though the potal's employed be a little more Ala than enough. The alcohol thus obtained contains a little potals diffolved, which may be separated by diftilling it in a water bath with a very fmall heat. The alcohol passes over, and leaves the potass behind. It is proper not to distil to dryness. This process is first mentioned by Lully. Alcohol may be obtained in the same manner from wine and from beer; which liquids owe their firength entirely to the quantity of that fubstance which they contain.

Alcohol is a transparent liquor, colourless like water, lisp of a pleasant smell, and a strong penetrating agreeable ites.

It is exceedingly fluid, and has never been frozen, though it has been exposed to a cold so great that the thermometer flood at -60° *.

Its specific gravity when pure is about 0,800.

It is exceedingly volatile boiling at the temperature of 176°; in which heat it assumes the form of an elattic fluid, capable of refifting the preffure of the atmosphere, but which condenies again into alcohol when that temperature is reduced. In a vacuum it boils at 56°, and exhibits the same phenomena: fo that were it not for the pressure of the atmosphere, alcohol would always exist in the form of an elastic fluid, as transparent and invifible as common air. This subject was first examined with attention by Mr Lavoisier + The fact, 7/1 however, had been known long before.

Alcohol has a strong affinity for water, and is miscible with it in all proportions. The specific gravity of all the different mixtures, in every proportion, and in all the different degrees of temperature, from 32 to 1000, has been lately afcertained with great accuracy by Sir Charles Blagden and Mr Gilpin. But as a very tull account of these interesting experiments has been given in the Encyclopædia in the article Spirituous Liquors, we do not think onrielves at liberty to repeat it here.

If alcohol be fet on fire, it burns all away with Op a blue flame without leaving any refiduum. Boerhaave itse observed, that when the vapour which escapes during fine this combustion is collected in proper vessels, it is found to confit of nothing but water. Junker had made the fame remark: and Dr Black suspected, from his own observations, that the quantity of water obtained, if properly collected, exceeded the weight of the alcohol confumed. This observation was confirmed by Lavoisier; who found that the water produced during the combuftion of alcohol exceeded the alcohol confumed by about th part *.

Different opinions were entertained by chemists about Fa the nature of alcohol. Stahl thought that it was com-1 posed of a very light oil, united by means of an acid to a quantity of water. According to Junker, it was composed of phlogiston, combined with water by means of an acid. Cartheufer, on the other hand, affirmed, that it contained no acid, and that it was nothing elle than pure phlogiston and water. But these hypotheses were mere affeitions supported by no proof whatever. Lavoisier was the first who attempted to analyse it.

He set fire to a quantity of alcohol in close vessels, L by means of the following apparatus: BCDE (fig. 6.) a is a veffel of marble filled with mercury. A is a strong glass vessel placed over it, filled with common air, and tirely on the strength of the spirit; but it is of no con- this vessel is put the lamp R silled with alcohol, the

veight of which has been exactly determined. On the vick of the lamp is put a small particle of phosphorus. The mercury is drawn up by fuction to the height IH. I'his glass communicates by means of the pipe LK with mother glass vessel S filled with oxygen gas, and placed over a vessel of water T. This communication may be hut up at pleasure by means of the stop-cock M.

Things being thus disposed, a crooked red hot iron wire is thrust up through the mercury, and made to touch the phosphorus. This inftantly kindles the wick, and the alcohol burns. As foon as the flame begins to grow dim, the stop-cock is turned, and a communication opened between the veffels S and A; a quantity of oxygen gas rushes in, and restores the brightness of the flame. By repeating this occasionally, the alcohol may be kept burning for fome time. It goes out, however, at last, notwith anding the admission of oxygen gas

The refult of this experiment, which Mr Lavoiser repeated a great number of times, was as follows:

The quantity of alcohol confumed amounted to 76,7083 grains troy.
The oxygen gas confumed amounted to 266,82 cu-

bic inches, and weighed 90,506 grains troy. The whole weight of the fub stances confumed, there-

fore, amounted to 167,2143 grains.

After the combustion, there were found in the glass vessel 115,41 cubic inches of carbonic acid gas, the weight of which was 78,1192 grains troy. There was likewife found a confiderable quantity of water in the veffel, but it was not possible to collect and weigh it. Mr Lavoisier, however, estimated its weight at 89,0951 grains; as he concluded, with reason, that the whole of the fubstances employed were still in the vessel. Now the whole contents of the veffel confifted of carbonic acid gas and water; therefore the carbonic acid gas and water together must be equal to the oxygen gas and alcohol which had been confumed.

But 78,1192 erains of carbonic acid gas contain, according to Mr Lavoiner's calculation +, 55,279 grains of oxygen: 90,506 grains, however, of oxygen gas had disappeared; therefore 35,227 grains must have been

employed in forming water.

35,227 grains of oxygen gas require, in order to form water, 6,038 grains of hydrogen gas; and the quantity of water formed by this combination is 41,265 But there were found 89,095 grains of water in the glass vessel; therefore 47,83 grains of water mult have existed ready formed in the alcohol.

It follows from all these data, that the 76,7083 grains of alcohol, confumed during the combustion, were com-

poled of

22,840 Carbon, 6,038 Hydrogen, 47;830 Water.

76,7 *.

Such were the consequences which Mr Lavoisier drew from his analysis. He acknowledged, however, that there were two fources of uncertainty, which rendered his conclusions not altogether to be depended upon. The first was, that he had no method of determining the quantity of alcohol confumed, except by the

difference of weight in the lamp before and after com- Alcohol. bustion; and that therefore a quantity might have evaporated without combustion, which, however, would be taken into the fum of the alcohol confumed. But this error could not have been great; for if a confiderable quantity of alcohol had existed in the state of vapour in the veffel, an explosion would certainly have taken place. The other fource of error was, that the quantity of water was not known by actual weight, but by calculation.

To this we may add, that Mr Lavoisier was not war-Ingredients ranted to conclude from his experiment, that the water of alcohol. found in the veffel, which had not been formed by the oxygen gas used, had existed in the alcohol in the state of water: he - s intitled to conclude from his data, that the ingredients of that water existed in the alcohol before combustion; but not that they were actually combined in the state of water, because that combination might have taken place, and in all probability did partly take place, during the combustion. It follows, therefore, from Mr Lavoitier's experiments, that alcohol, fuppoling he used it perfectly pure, which is not probable, is composed of

0,2988 parts carbon, 0,1840 parts hydrogen, 0,5172 parts oxygen.

1,0000

But it gives us no information whatever of the manner in which these ingredients are combined. That alcoholcontains oxygen, has been proved by a very ingenious set of experiments performed by Messirs Fourcroy and Vauquelin. When equal parts of alcohol and fulphuric acid are mixed together, a quantity of caloric is difengaged, fufficient to elevate the temperature of the mixture to 190°. Bubbles of air are emitted, the liquor becomes turbid, assumes an opal colour, and at the end of a few days a deep red. When examined, the fulphuric acid is found to have fuffered no change; but the alcohol is decomposed, partly converted into water and partly into ether, a fubstance which we shall deferibe immediately. Now, it is evident that the alcohol could not have been converted into water unless it had contained oxygen *

When equal parts of fulphuric acid and alcohol are fon's four-mixed together and heat applied, the mixture boils at 208°, and a liquid equal to half the weight of the alcohol comes over into the receiver. This liquid is

Ether is obscurely hinted at in some of the older che- Ether. mical authors, but little attention was paid to it till a paper appeared in the Philosophical Transactions for 1730, written by a German, who called himself Frobenius (G), containing a number of experiments on it. In this paper it first received the name of ether.

Ether is limpid and colourless, of a very fragrant its properfmell, and a hot pungent taste. Its specific gravity is ties. 0,7394. It is exceedingly volatile, boiling in the open air at 98°, and in a vacuum at - 20° Were it not therefore for the pressure of the atmosphere, it would always exist in a gaseous state. Ether unites with water in the proportion of ten parts of the latter to one of

Alcohol. the former *. It is exceedingly inflammable, and when kindled in the state of vapour burns with rapidity, or ra-Lauraguais, ther explodes, if it be mixed with oxygen gas.

Chemitts entertained various opinions respecting the Theory of nature of ether. Macquer supposed, that it was merely alcohol deprived by the acid of all its water. But it was generally believed that the acid entered partly into its composition. Since the nature of acids has become better known, a great number of philosophers have supposed that ether is merely alcohol combined with a quantity of oxygen furnished by the acid. The real composition of this singular substance has been lately afcertained by the experiments of Fourcroy and Vauquelin.

"A combination (fay they) of two parts of fulphuric acid and one part of alcohol elevates the mperature to 201°, becomes immediately of a deep red colour, which changes to black a few days afterwards, and emits a

fmell perceptibly ethereal.

"When we carefully observe what happens in the combination of equal parts of alcohol and concentrated fulphuric acid exposed to the action of caloric in a proper

apparatus, the following phenomena are feen:

"1. When the temperature is elevated to 208°, the fluid boils, and emits a vapour which becomes condenfed by cold into a colourless, light, and odorant liquor, which from its properties has received the name of ether. If the operation be properly conducted, no permanent gas is difengaged until about half the alcohol has paffed over in the form of ether. Until this period there passes absolutely nothing but ether and a small portion of water, without mixture of fulphurous or of carbonic acid.

" 2. If the receiver be changed as foon as the fulphurous acid manifests itself, it is observed that no more ether is formed, but the sweet oil of wine, water, and acetous acid, without the difengagement hitherto of a fingle bubble of carbonic acid gas. When the fulphuric acid conflitutes about four-fifths of the mass which remains in the retort, an inflammable gas is difengaged, which has the smell of ether, and burns with a white oily flame. This is what the Dutch chemists have called carbonated bydrogen gas, or olefiant gas, because when mixed with the oxy-muriatic acid it forms oil. At this period the temperature of the fluid contained in the retort ris elevated to 2300 or 2340.

"3. When the sweet oil of wine ceases to flow, if the receiver be again changed, it is found that nothing more passes but sulphurous acid, water, carbonic acid gas; and that the refiduum in the retort is a black mase, confifting for the most part of sulphuric acid thickened by

carbon.

"The feries of phenomena here exposed will justify

the following general inductions:

"I. A small quantity of ether is formed spontaneously, and without the affiftance of heat, by the combination of two parts of concentrated fulphuric acid and one part of alcohol.

" 2. As foon as ether is formed, there is a production of water at the same time; and while the first of these compositions takes place, the sulphuric acid undergoes no change in its intimate nature.

" 3. As foon as the fulphurous acid appears, no more ether is formed, or at least very little; but then there paffes the sweet oil of wine, together with water and acetous acid.

4. The sweet oil of wine having ceased to come over,

nothing further is obtained but the fulphurous and care along bonic acids, and at last sulphur, if the distillation be carried to dryness.

"The operation of ether is therefore naturally divided into three periods: the first, in which a small quantity of ether and water are formed without the affiftance of heat; the fecond, in which the whole of the ether which can be obtained is disengaged without the accompaniment of fulphurous acid; and the third, in which the fweet oil of wine, the acetous acid, the fulphurous acid, and the carbonic acid, are afforded. The three stages have no circumstance common to all, but the continual formation of water, which takes place during the whole

of the operation.

"The ether which is formed without the affiftance of caloric, and the carbon which is feparated without decomposition of the sulphuric acid, prove that this acid acts on alcohol in a manner totally different from what has hitherto been supposed. It cannot, in fact, be affirmed, that the acid is altered by the carbon, because daily experience shews that no sensible attraction takes place between these two bodies in the cold; neither can it be affected by the hydrogen; for in that case sulphurous acid would have been formed, of which it is known that no trace is exhibited during this first period. We must therefore have recourse to another species of action, namely, the powerful attraction exercised by the sulphuric acid upon water. It is this which determines the union of the principles which exist in the alcohol, and with which the concentrated acid is in contact: but this action is very limited if the acid be small in quantity; for an equation of affinity is foon established, the effect of which is to maintain the mixture in a state of repose.

"Since it is proved that ether is formed in the cold by the mixture of any quantities of alcohol and fulphuric acid, it is evident that a mass of alcohol might be completely changed into ether and vegetable acid by using a sufficient abundance of sulphuric acid. It is equally evident that the fulphuric acid would not by this means undergo any other change than that of being diluted with a certain quantity of water. This observation proves, that alcohol contains oxygen, because water cannot exist without this principle, which must be afforded by the alcohol only, fince the fulphuric acid fuffers

no decomposition.

"We must not, however, imagine, from these facts, that ether is alcohol minus oxygen and hydrogen. Its properties alone would contradict this; for a quantity of carbon proportionally greater than that of the hydrogen is at the fame time separated. It may, in fact, be conceived, that the oxygen, which in this case combines with the liydrogen to form water, not only faturated that hydrogen in the alcohol, but likewife the carbon. So that, inflead of confidering ether as alcohol minns hydrogen and oxygen, we must, by keeping an account of the precipitated carbo n and the small quantity of hydrogen contained in the water which is formed, regard it as alcohol plus hydrogen and oxygen.

"The foregoing are the effects produced by a combination of alcohol and fulphunic acid, spontaneously produced without foreign heat. Let us, in the next place, observe, how this combination is effected when caloric is added. The phenomena are then very different, tho

some of the results are the same.

"In the first place, we must observe, that a combinaloobol. tion of fulphuric acid and alcohol in equal parts does not boil at less than 207 degrees of temperature, while that of alcohol alone boils at 176. Now fince ebulition does not take place till the higher temperature, it is clear that the alcohol is retained by the affinity of the fulphuric acid, which fixes it more confiderably. Let us also confider that organic bodies, or their immediate products, expoted to a lively brisk heat, without the possibility of escaping speedily enough from its action, suffer a partial or total decomposition, according to the degree of temperature. Alcohol undergoes this last alteration when passed through an ignited tube of porcelain. By this sudden decomposition it is converted into water, carbonic acid, and carbon. The reason, therefore, why alcohol is not decomposed when it is submitted alone to heat in the ordinary apparatus for distillation, is, that the temperature at which it rifes in vapours is not capable of effecting the separation of its principles; but when it is fixed by the fulphuric acid or any other body, the elevated temperature it undergoes, without the possibility of disengagement from its combination, is sufficient to effect a commencement of decomposition, in which ether and water are formed, and carbon is depofited. Nothing more therefore happens to the alcohol in thefe circumstances than what takes place in the distillation of every other vegetable matter in which water, oil, acid, and coal, are afforded.

"Hence it may be conceived that the nature of the products of the decomposition of alcohol must vary according to the different degrees of heat; and this explains why at a certain period no more ether is formed but the sweet oil of wine and acetous acid. In fact, when the greatest quantity of the alcohol has been changed into ether, the mixture becomes more dense, and the heat which it acquires previous to ebullition is more confiderable. The affinity of the acid for alcohol being increased, the principles of this acid become separated; fo that, on the one hand, its oxygen feizes the hydrogen, and forms much water, which is gradually volatilized; while, on the other, the ether retaining a greater quantity of carbon, with which at that temperature it can rife, affords the sweet oil of wine. This last ought therefore to be considered as an ether containing an extraordinary portion of carbon, which gives it more denfity, less volatility, and a lemon yellow co-

"During the formation of the fweet oil of wine, the quantity of carbon which is precipitated is no longer in the fame proportion as during the formation of ether.

"What we have here stated concerning the manner in which ether is formed by the simultaneous action of the sulphuric acid and heat, appears so conformable to truth, that nearly the same effects may be produced by a caustic fixed alkali — In this case also a kind of ether and a sweet oil of wine are volatilized, and coal is precipitated. It is therefore only by fixing the alcohol that the sulphuric acid permits the caloric to operate a fort of decomposition. It may also be urged as a proof of this affertion, that the sulphuric acid, which has served to make ether as far as the period at which the sweet oil of wine begins to appear, is capable of saturating the same quantity of alkali as before its mixture with the alcohol ‡."

Ether may also be obtained by means of several other Suppl. Vol. I. Part I.

acids. The different liquids thus formed are diffinguished by prefixing the name of the acid used in the process. Thus the ether above described is called fulphuric ether; that obtained by means of utric acid, nitric ether, and so on. There are several minute shades of difference between these various ethers, which have not yet been properly enquired into.

Alcohol is capable of diffolving a great many bo Subfrances dies. A confiderable number of these, with the quan-foluble in tities foluble, is exhibited in the following tables.

III. Substances insoluble with Alcohol.

Sulphat of foda, Sugar of milk, magnefia, Borax, Sulphite of foda, Tartar, Tartrite of foda and Alum, Sulphat of ammonia, potais, Phosphoric acid, lime, Nitrat of lead, barytes*, mercury, iron (green), Muriat of lead, copper, filver t, filver, Common falt, mercury, Carbonat of potafs, zinc, potals,

These have been chiefly borrowed from tables which Mr de Morveau published in the Journal de Physique July 1785, and which were drawn up for the most part from the experiments described in Wenzel's Treatife on Affinities.

Itsaffinities. The affinities of alcohol are very imperfectly known. Those stated by Bergman are as follows:

Water, Ether, Volatile oil, Sulphurets of alkalies.

CHAP. III. Of OILS.

360 Difcovery of oil

+ Herodot. lib ii. 59, and 62.

36I

Fixed oils.

OIL, which is of fuch extensive utility in the arts, was known at a very remote period. It is mentioned in Genefis, and during the time of Abraham was even * Gen. xv. used in lamps *. The olive was very early cultivated, and oil extracted from it in Egypt. Cecrops brought it from Sais, a town in Lower Egypt, where it had been cultivated from time immemorial, and taught the Athenians to extract oil from it. In this manner the use of oil became known in Europe +. But the Greeks feem to have been ignorant of the method of procuring light by means of lamps till after the fiege of Iroy; at least Homer never mentions them, and constantly describes his heroes as lighted by torches of wood. Oils are divided into two classes, Fixed and Volatile;

> I. The FIXED OILS, called also fat or expressed oils, are numerous, and are obtained, partly from animals and partly from vegetables, by fimple expression. As inflances, we shall mention whale oil or train oil, obtained from the blubber of the whale; olive oil, obtained from the fruit of the olive; lintfeed oil and almond oil, obtained from lintfeed and almond kernels. Fixed oils may also be obtained from poppy seeds, hemp seeds, beach mast, and many other vegetable substances.

each of which is diftinguished by peculiar properties.

All these oils differ from each other in several parti culars, but they also possess many particulars in common. Whether the oily principle in all the fixed oils is the same, and whether they owe their differences to accidental ingredients, is not yet completely ascertained, as no proper analysis has hitherto been made; but it is exceedingly probable, as all the oils hitherto tried have been found to yield the same products. In the present state of our knowledge, it would be useless to give a particular description of all the fixed oils, as the differences between them have not even been accurately af- Oils. certained. We shall content ourselves, therefore, with giving the characters which diftinguish fixed oils in general, and an analysis of one oil, by way of specimen.

Fixed oils are infoluble in alcohol, which diftinguishes Their prothem from volatile oils. They are also insoluble in wa-perties.

They have an unctuous feel, are transparent while fluid, are destitute of fmell, and have a mild insipid kind

They are all susceptible of becoming solid by expofure to a fufficient degree of cold. Olive oil and alt Chaptal's mond oil freeze at 101 degrees 1.

They are capable of being converted into vapour by English heat; but require for that purpose a temperature confiderably fuperior to that of boiling water. Olive oil (ranf. iii. 43, boils at 600°, and most of the fixed oils hitherto tried require nearly the same degree of heat.

When in the state of vapour they take fire on the approach of an ignited body, and burn with a yellowish white flame. It is upon this principle that candles and lamps burn. The tallow or oil is first converted into the state of vapour in the wick; it then takes fire, and supplies a sufficient quantity of heat to convert more oil into vapour; and this process goes on while any oil remains. The wick is necessary to present a sufficiently small quartity of oil at once for the heat to act upon. If the heat were fufficiently great to keep the whole oil at the temperature of 600, no wick would be necessary, as is obvious from oil catching fire fpontaneoully when it has been raised to that temperature.

Mr Lavoiher analysed olive oil by burning it in pre- 363 cifely the same apparatus as that which he employed for o ive oil. aualyfing alcohol.

The quantity of oil confumed amounted to 15,79

grains troy.

The quantity of oxygen gas amounted to 50,86 gr. troy. The whole amount therefore of the substances confumed during the combustion is 66,65 grains troy.

The carbonic acid obtained amounted to 44.50 gr. There was also a considerable quantity of water, the weight of which could not be accurately ascertained: but as the whole of the fubstances confumed were converted into carbonic acid gas and water, it is evident, that if the weight of the carbonic acid be subtracted from the weight of these substances, there must remain precifely the weight of the water. Mr Lavoiser accordingly concluded, by calculation, that the weight of the water was 22,15 grains. Now the quantity of oxygen in 44,50 grains of carbonic acid gas is 32,04 grains, and the oxygen in 22,15 grains of water is 18,82 grains; both of which taken together amount to 50,86 grains, precisely the weight of the oxygen gas employed. There does not appear therefore to be any oxygen in olive oil.

The quantity of carbon in 44,50 grains of carbonic acid gas is 12,47 grains; and the quantity of hydrogen in 22,15 grains of water is 3,32 grains; both of which, when taken together, amount to 15,79 grains, which is the weight of the oil confumed.

It follows, therefore, from this analysis, that 15,79 grains of olive oil are composed of

> 12,47 Carbon, 3,32 Hydrogen.

Olive

364

365

368

Their affi-

mities.

Dis. Olive oil therefore is composed of about

79 Carbon, 21 Hydrogen.

100*

In what manner these substances are combined, cannot & Four. de be learned from this analysis. Whether they combine directly, and faturate each other in that proportion, as is 2 7, July most probable or whether the hydrogen is combined previously with a part of the carbon, and that compound combining with a certain quantity of carbon, forms oil, is altogether uncertain. Yet these questions are of the utmost importance; and till the method of solving them be discovered, we never can acquire any precise ideas about the constituent parts of a great number of subflances, which, though formed ultimately of the fame ingredients, differ very much in their properties from one another; as wax and oil; alcohol, fugar, and When fixed oils are exposed to the atmosphere, they

1 icidity. become thick, acquire a brown colour, and a peculiarly unpleasant smell: they are then said to be rancid. When oil is poured upon water, so as to form a thin layer on its furface, and is in that manner exposed to the atmosphere, these changes are produced much sooner, the oil becomes thicker, and affumes an appearance very much refembling wax. Berthollet, who first examined these phenomena with attention, ascribed them to the action of light: but Sennebier observed, that no fuch change was produced on the oil though ever fo long exposed to the light, provided atmospherical air was excluded; but that it took place on the admission of oxygen gas, whether the oil was exposed to the light or not +. It cannot be doubted, then, that it is owing in xi. 89. to the combination of oxygen. All substances that are capable of fupplying that principle, the metallic oxyds, for instance, and several of the acids, produce the same effect upon oils; and it is a known fact, that oil is capable of reducing many of the metallic oxyds to the metallic state, and consequently that it has a stronger affinity for oxygen.

Mr Chaptal has supposed that oils become rancid merely because they contain a quantity of mucilage, with which the oxygen combines, and that when oxygen combines with fixed oils, it produces a different effect, converting them into what is called drying oils.

It is certain that oils contain a quantity of mucilage; but some change is evidently produced on the oils themfelves by rancidity; for no agitation in water is capable of restoring them to their former state, although water deprives them of their mucilage. Drying oils, so called berying oils, cause they are capable of drying completely when spread out, a property which renders them useful in painting, feem, as Sennebier observes, to be completely deprived of mucilage; for, in order to render an oil drying, it must be boiled, which evaporates or decomposes all the muci-

lage: they feem also to lose part of their hydro-

Fixed oils are capable of diffolving fulphur at their Berthollet. boiling temperature. The folution is very fetid, owing Fixed oils to a partial decomposition of the oil. Hydrogen gas diffolve sulflies off, having a quantity of fulphur diffolved in it. phur, When the solution cools, the sulphur crystallizes.

Fixed oils diffolve phosphorus. The folution is lu- And phosminous, from the flow combustion of the phosphorus. Phorus.

Fixed oils are capable of combining with many of the metallic oxyds. The compounds are called metallic foaps. Several of the oxyds are decomposed by being boiled in oils.

Fixed oils combine also with the alkaline earths and with alumina. The compounds are called earthy foaps.

The affinities of the oils are as follows. Nitric acid, Lime, Muriatic, Barytes, Sulphurous, Fixed alkalies, Sulphuric, Magnesia, Acetous, Ammonia, Sulphur, Oxyd of mercury, Phosphorus (1). Other metallic oxyds (H),

Alumina. II. VOLATILE OILS, called also effential oils, are all Volatile obtained from vegetables. They have a strong aroma. oils. tic fmell, and a pungent acrid taste. They are so volatile, that they may be distilled by the heat of boiling water. They are foluble in alcohol, but not in water. They evaporate on the application of heat, without leaving any stain behind them, which is not the case with the fixed oils. By this telt, accordingly, it is easy to discover whether they have been adulterated with any of the fixed oils. Let a drop of the volatile oil fall upon a sheet of writing paper, and then apply a gentle heat to it. If it evaporates without leaving any flain upon the paper, the oil is pure; but if it leaves a stain, it has been contaminated with some fixed oil or other.

Volatile oils are very numerous, and differ from one another, in fluidity and weight, in their freezing point, and in feveral other particulars. Little attention has been paid to the greatest part of them, because few of them have been found of any use. The principal quality for which they are valued is their odour. Some of them are obtained by expression, as oil of bergamot, lemons, oranges; others by distillation, as oil of peppermint, thyme, lavender, &c. It would be useless, even if it were possible, to give a particular description of all the volatile oils.

They are more inflammable than the fixed oils; a Their proquality which they owe to their volatility. As far perties. as experiments have hitherto been made, they feem to confift of carbon and hydrogen; but nothing is known concerning the proportions of these ingredients. They thicken when exposed to the air, probably by combining with oxygen, and form refins (K). When Pp2

(H) Their order not well ascertained.

(1) The first column was ascertained by Berthollet. The last is to be considered as unconnected with the first. On account of the affinity of these two classes of bodies for each other, it has not been possible to discover which

of them has the greatest affinity for oil. (K) Relins are concrete vegetable juices; the distinguishing property of which is infolubility in water and solubility in alcohol. Common refin, or rosin, from which they derive their name, is one of them; and sealing wax confifts almost entirely of another.

Alkalier.

When exposed to cold, or when kept for a long time, fome of them deposite crystals resembling the acid of benzain (L'.

They diffolve fulphur, and form what have been call-

ed balfams of fulphur.

They are capable of combining with most of the subflances that unite with fixed oils. Their affinities, which certainly differ from those of fixed oils, have not yet been properly afcertained.

CHAP. IV. Of ALKALIES.

Pro erties

Substances possessed of the following properties are of alkalies. called alkalies:

1. Incombustible.

2. Capable of converting vegetable blues to a green.

4. A hot caustie taste.

4. Very foluble in water, even when combined with carbonic acid.

There are three alkalies, potafs, foda, and ammonia. The two first are called fixed alkalies, because a very violent heat is necessary to volatilize them; the last is called volatile alkali, because it very easily assumes a gafeous form, and is confequently diffipated by a very moderate degree of heat.

SECT. I. Of Potafs.

372 Method of procuring potafs.

IF a sufficient quantity of wood be burnt to ashes, and these ashes be afterwards washed repeatedly with water till it comes off free from any tafte, and if this liquid be filtrated and evaporated to dryness, the fubstance which remains behind is potass; not, however, in a state of purity, for it is contaminated with several other substances; but sufficiently pure to exhibit many of its properties. In this state, it occurs in commerce under the name of potash. It may be purified considerably, by putting it in a crucible, keeping it red hot for some time; then diffolving it in water, filtrating it, and evaporating it again to dryness. By the following method it may be obtained nearly pure: Mix together equal quantities of nitre and carbon, and put them by little and little into a red hot crucible. They burn with a vivid flame, and leave behind them a quantity of potals. This is to be diffolved in water, filtrated, and evaporated to drynels. Or potals may be obtained by burning tartar wrapt up in brown paper and placed in a crucible (M).

The potals procured by these last processes is exceedingly white; it is not, however, quite pure; for it is combined with a fubstance which blunts all its properties confiderably. This fubstance is carbonic acid gas; from which it may be separated by dissolving it, and mixing with it an equal quantity of lime made into a paste with water. The lime has a greater affinity for carbonic acid gas, and therefore combines with it; and the pure potals remains diffolved in the water, and may be separated from the lime by filtrating the mixture. This

process. however, must be performed in close vessels; Alkalies, for there is a little carbonic acid gas in the atmosphere, which would again combine with the potals if it were allowed to stand exposed to the air

It is then to be evaporated till a thick pellicle anpears on its furface, and afterwards allowed to cool; and all the crystals which have formed are to be separated, for they confift of foreign falts. The evaporation is then to be continued in an iron pot; and, during the procels, the pellicle which forms on the surface is to be carefully taken off with an iron skimmer. When no more pellicle appears, and when the matter ceases to boil, it is to be taken off the fire, and must be constant. ly agitated while cooling with an iron spatula. It is then to be dissolved in double its own weight of cold water. This folution is to be filtered and evaporated in a glass retort till it begins to deposite regular crystals. If the mass consolidates ever so little by cooling, a small quantity of water is to be added, and it must be heated again. When a sufficient number of crystals have been formed, the liquor which fwims over them, and which has affumed a very brown colour, must be decanted off, and kept in a well-closed bottle till the brown matter has subsided, and then it may be evaporated as before, and more crystals obtained. The crystals may then be dissolved in pure water. By this process, which was invented by Mr Lowitz of Petersburgh *, potass may * Nichollan, be obtained in a state of the greatest purity. Thei. 164. shape of its crystals is very different, according to the way in which they have been produced. When allowed to form in the cold, they are octahedrons in groups, and contain 0.43 of water: When formed by evaporation on the fire, they affume the figure of very thin transparent blades of extraordinary magnitude, which, by an affemblage of lines croffing each other in prodigious numbers, present an aggregate of cells or cavities, commonly fo very close, that the vessel may be inverted without lofing one drop of the liquid which it contains +.

Pure potals is so exceedingly corrosive, that when applied to any part of the body, it destroys it almost instantaneously. On account of this property, it has been called caustic, and is often used by surgeons under the name of the potential cautery, to open abscesses, and destroy useless or hurtful excrescences.

As potals is never obtained at first in a state of pu- 373 disrity, but always combined with carbonic acid, it was covery of long before chemists understood to what the changes the cause of produced upon it by lime were owing. According to its caustifome, it was deprived of a quantity of mucilage, in ery. which it had formerly been enveloped; while, according to others, it was rendered more active by being more comminuted. At last, in 1756, Dr Black published the celebrated experiments which we have so often mentioned; in which he proved, by the most ingenious and satisfactory analysis, that the potass which the world had confidered as a fimple fubstance, was really a

(L) See a paper by Margueron on this subject, Ann. de Chim. xxi. 174.

(M) That potals was known to the ancient Gauls and Germans, cannot be doubted, as they were the inventors of foap, which, Pliny informs us, they composed of ashes and tallow. These ashes (for he mentions the ashes of the beech tree particularly) were nothing else but potals; not, however, in a state of punity. Plinii, lib. xviii. c. 51. The xviia, too, mentioned by Aristophanes and Plato, appears to have been a ley made of the same

compound, confishing of potala and carbonic acid; that line deprived it of this acid; and that it became more

active by becoming more simple.

While Dr Black was thus occupied in Scotland, Mr Meyer was employed in Germany in the same researches; from which, however, he drew very different conclufions. His Essays on Lime appeared in 1764. Pouring into lime water a folution of potals (carbonat of potals), he obtained a precipitate, which he found not to differ from lime-stone. The alkali had therefore deprived the lime of its causticity and its active properties; and these very properties it had itself acquired. From which he concluded, that the causticity of lime was owing to a particular acid with which it had combined during its calcination. The alkali deprived the lime of this acid, and therefore had a stonger affinity for it. To this acid he gave the name of acidum pingue or caufticum. It was, according to him, a fubtile elastic mixt, analogous to fulphur, approaching very nearly to the nature of fire, and actually composed of an acid principle and fire. It was expansible, compressible, volatile, aftringent, capable of penetrating all veffels, and was the cause of causticity in lime, alkalies, and metals. This theory was exceedingly ingenious, and it was supported by a vast number of new and important facts. But notwithstanding the reputation and acknowledged genius and merit of its author, it never gained many followers; because the true theory of causticity, which had been already published by Dr Black, foon became known on the continent; and, notwithstanding some opposition at first, foon carried conviction into every unprejudiced mind. Even Mr Meyer himself readily acknowledged its truth and importance, though he did not at first, on that account, give up his own theory.

When potass is exposed to the action of fire, it first becomes foft, and melts into a transparent liquid at the

commencement of ignition.

When exposed to the air, it attracts moisture very full, and is foon converted into a liquid. It attracts, at the same time, carbonic acid gas, for which it has a very strong affinity. It is impossible, then, to keep potals in a state of purity, except in very close vessels.

It unites readily with fulphur, and forms fulphuret of potass. This compound may be formed two ways; either by melting the ingredients together, or by boiling them in water, and then filtrating the folution. Sulphuret of potals when dry, in which state it is obtained by the first process, is of a brown colour. It is soluble

in water, and very foon attracts moisture.

While dry it produces no change upon the air of the atmosphere, as Messrs Dieman, Van Troostwyck, Nieuwland, and Bondt, ascertained by experiment *. But when moistened with water, it very soon absorbs. difficulty of decomposing it, must be allowed to be one all the oxygen gas which happens to be in the veffel inwhich it is inclosed, and leaves nothing but azotic gas. This fact was first observed by Scheele, and induced him to use sulphuret of potals for an eudiometer, or inflrument to measure the quantity of oxygen contained in any given portion of atmospheric air.

If fulphuret of potals be allowed to remain moift, and in contact with the atmosphere, it is gradually converted into fulphat of potals by the fulphur combining with oxygen, and forming fulphuric acid. At the same time the sulphuret emits a fetid smell, which is known to be the odour of fulphurated hydrogen gas.

The fulphuret then decomposes the water with which Alkabes. it is mixed. Very little sulphurated hydrogen gas, however, is emitted, except an acid (the fulphuric, for instance) be poured upon the mixture, and then it is given out very copiously. The reason of this is, that there is an affinity between the potass and this gas. Accordingly it is retained by the potals after it is formed. But as the acids have a much stronger affinity for potals, as foon as any of them is poured in the gas is oblined to separate t.

If liquid sulphuret of potals be kept in close vessels, it is not decomposed except in part; because as soon as the alkali is faturated with the fulphurated hydrogen gas, the action of the fulphur on the water is at an end *. * Ibida

The explanation of the action of this fulphuret on the atmosphere, which the Dutch chemists above-men-

tioned give from these data, is as follows:

Sulphuret of potafs decomposes water; fulphurated hydrogen gas is formed, and absorbed by the alkali. This gas has a strong affinity for oxygen, which it absorbs from the atmosphere: the hydrogen combines with this oxygen, and forms water; and the fulphur is again precipitated, or rather left combined with the pot-Water is again decomposed by the attraction of the fulphur for oxygen; new fulphurated hydrogen gas is again formed; again absorbed; again attracts oxygen gas; and is again decomposed. And this process goes on till the whole of the fulphur has combined with oxygen, and confequently till the fulphuret is converted into a fulphat †. — The only part of this theory which † Ibid. requires confirmation is the action of fulphurated hydrogen gas on oxygen gas, and the consequent formation of water. And this they have rendered not improbable, by shewing that sulphurated hydrogen gas combined with alkali has the property of absorbing oxygen gas from the atmosphere t.

Potats unites with phofphorus by fusion, and forms 305 a pholphuret of potals. Little is known concerning Pholphuret its properties, except that it produces phosphurated hy. of potals.

Potals feems also capable of combining with carbon. - 37 Potals does not combine with the metals; but it Glass.

unites with many of their oxyds.

When a folution of potass is boiled upon silica recently procured, it dissolves part of it. As the solution cools, it assumes the appearance of a jelly, even though previously diluted with 17 times its own weight

When equal parts of filica and potass are melted to-ii. 32. gether, they combine and form glass. A substance which, whether we consider its hardness, beauty, and transparency, its amazing ductility while hot, or the of the most useful compounds ever invented by man.

When the quantity of potass is double or triple that of the silica, the glass is soluble in water, and forms

what is called liquor filicum.

Potass seems also capable of combining in the same manner with barytes, lime, magnefia, and alumina; but these combinations have never been examined with attention. Lime, however, is often added to the materials for making glass, and is supposed to increase its hardness and folidity.

The metallic oxyds have the property of rendering glass more fusible, and of communicating various co-

378 Soap.

Potaf.

Alkalies. lours to it; they accordingly very often make a part of its composition. The colours communicated by these oxyds will appear from the following table:

> Metallic Oxyds. Colour communicated to Glass. Oxyd of gold and tin, - Purple.

Silver, - - -Yellow or golden.

Potass combines readily with fixed oils, and forms the compound known by the name of foap.

Potass has never yet been decomposed. Several chemists, indeed, have conjectured, that it was a compound whether a compound of lime and azot; and fome perfors have even endeavoured to prove this by experiment; but none of their proofs are at all fatisfactory. We ought, therefore, in strick propriety, to have affigned it a place in the first part of this article: but this would have separated the alkalies from each other, and would have introduced a consusion into the article, which would have more than counterbalanced the logical exactness of the arrange. ment. Besides, we are certain, from a variety of facts, that all the alkalies are compounds: One of them has actually been decompounded; and the other two have been detected in the act of formation, though the ingredients which compose them have not hitherto been discovered.

> Whether potafs contains lime is a different question. Were we to judge from analogy, we should suppose, that the four alkaline earths, and the three alkalies, possess one common principle. They have a great number of common properties, and perhaps ought to be classed altogether under the name of alkalies.

> That azot enters into the composition of all these bodies, as Fourcroy has conjectured, is far from improbable. One alkali, as we shall foon see, actually contains azot. But no conclusion can be drawn till future discoveries have lifted off the veil which at present ob-

structs our view.

The affinities of potafs are as follows:

Sulphuric acid, Nitric, Muriatic, Sebacic, Fluoric, Phosphoric,

Oxalic, Tartarous, Arfenic, Succinic, Citric, Formic. Lactic, Benzoic. Sulphurous, Acetons, Saccholactic. Boracic, Nitrous, Carbonic, Pruffic, Oil, Sulphur, Phosphorus, Water.

The place of the metallic oxyds has not yet been ascertained.

SECT. II. Of Soda.

Soda, called mineral alkali, because it is found in the earth, was known to the ancients under the names of vilen and nitrum (P) It was long confounded with potass; and perhaps was never properly diftinguished from it till Du Hamel published a paper on the subject in 1736.

Its properties, while pure, are precifely the fame Propert with those of potass, excepting only that its affinity for of fooda. other bodies is not fo firong; it does not, therefore, require any particular description. We ought to mention, however, that it differs from potass in one particular; potass attracts moisture in the air, but soda parts with it, and when exposed to the atmosphere, soon crumbles down into a dry powder.

It is capable of combining with all the fubstances with which potals unites; but it forms compounds poffessed, in general, of very different properties from those of the compounds into which potals enters.

It is reckoned more proper than potals for forming

glass and foap.

Some chemists have supposed that it is composed of magnesia and azot; but their proofs are insufficient.

The order of its affinities is the same with that of

SECT. III. Of Ammonia.

Ammonia (Q), volatile alkali, or hartsborn, as it is Discover called in commerce, is mentioned as early as the 15th of amm century. Both Bafil Valentine and Raymond Lully nia. described the methods of procuring it. Dr Black was the first who distinguished pure ammonia from the carbonat of ammonia, or ammonia combined with carbonic acid; and Dr Priestley first discovered the method of obtaining it in a state of complete purity.

To obtain pure ammonia, mix common fal ammoniac with three parts of flacked lime; apply heat; and re-

(N) If the glass be made with foda.

(o) But reddish if the glass be formed of soda. Klaproth.

(P) The Alfor of the Athenians was evidently the fame substance; and so was the המר of the Hebrews.

(a) We have adopted this word, which is Dr Black's, because we think it preferable to ammoniac or ammoniaca, the words proposed and used by the French chemists.

ceive the product in a vessel filled with mercury standing in a bason of mercury. A gas comes over, which is pure ammonia *. This gas is transparent like common air, and is not condensed by cold.

Its specific gravity is 0,000732. It is to common

air as 600 to 1000 +.

It has a very strong, but not unpleasant smell. Ani-8 mals cannot breathe it without death. When a lighted candle is let down into this gas, it goes out three or four times successively; but at each time the flame is confiderably enlarged by the addition of another flame of a pale yellow colour, and at last this slame deteends , from the top of the vessel to the bottom ‡.

Water absorbs this gas with avidity. It disappears

almost instantly on the introduction of a little water. From an experiment of Dr Prieltley, it appears that water faturated with this gas is of the specific gravity

This water acquires the fmell of ammonia. It has a very strong difogueeable taste, and converts vegetable

colours to a green.

Ammonia in the state of gas has no effect upon fulphur or phosphorus. Carbon absorbs it; probably because it contains water. Neither hydrogen nor azot produce any alteration on it ¶

Alcohol and ether absorb it in considerable quantity*. Dr Priestley discovered, that when electric explosions were made to pals through this gas, its bulk was grats, dually augmented to thrice the space which it formerly occupied. It was then mostly converted into hydrogen gas. He discovered, too, that heat produced the very same effect +. These experiments prove that hydrogen enters as an ingredient into the composition of ammonia.

Mr Scheele observed, that when ammonia was treated with the oxyds of manganefe, gold, or mercury, the oxyds were reduced; the ammonia disappeared; and nothing remained but a quantity of azotic gas. These facts induced Bergman to conjecture, that ammonia was composed of hydrogen and azot : a conjecture which has been fully confirmed by the experiments of Berthollet.

This ingenious chemist observed, that if oxy-muriatic acid and ammonia be mixed, an effervescence takes place; azot is difengaged, a quantity of water formed, and the oxy-muriatic acid is converted into common muriatic acid. Now the fubftances mixed were ammonia and oxy-muriatic acid, which is composed of oxygen and muriatic acid; the products were, muriatic acid, azot, and water, which is composed of oxygen and liydrozen. The oxygen of the water was furnished by the acid; the other products must have been furnished by the ammonia, which has disappeared. Ammonia, therefore, must be composed of azot and hydrogen. Mr Berthollet proved, that ammonia was composed of there ingredients by a number of other experiments. For instance, if the oxyd of copper be heared in contact with ammoniacal gas, it is restored to the metallic state; the ammonia disappears, a quantity of water is It follows from formed, and azotic gas is disengaged Mr Berthollet's experiments, that ammonia is composed Par. of 121 parts of 20t and 29 of hydrogen ‡. According to Dr Austin, it is composed of 121 parts of azot,

After the composition of ammonia had been thus afcertained, it became a question of some consequence,

and 32 of hydrogen *

Whether it could be formed artificially? Dr Auffin Alkalies. accordingly mixed hydrogen and azotic gas together in the proper proportions, and endeavoured to make Formation them combine by the application of heat, by electricity, of ammoand by cold; but he found, that while thefe two fub-nia. stances were in a gaseous state, they could not be combined by any method which he could devife. It could not be doubted, however, that the combination often takes place when these bodies are presented to each other in a different form. Dr Prieftley + and Mr Kirwan + had + On Air, ii. actually produced it, even before its composition was ton Hepaknown. Accordingly he found, that when tin is moilten- tic Air, & iii. ed with nitric acid, and after being allowed to digent for a minute or two, a little potafs or lime is added, amnionia is immediately exhaled *. In that case, the nitric * Dr Aufacid and the water which it contains are decomposed; the tin. oxygen of each unites with the tin, and reduces it to the state of an oxyd; and at the same time the hydrogen of the water combines with the azot of the acid, and forms ammonia, which is driven off by the stronger affinity of the potass or lime. Dr Austin succeeded also in forming ammonia by several other methods. He introduced into a glass tube filled with mercury a little azotic gas, and then put into the gas some iron-llings moiltened with The iron decompoles the water and combines with its oxygen; and the hydrogen meeting with azot at the moment of its admission, combines with it, and forms ammonia. This experiment flews, that the gafeous state of the azot does not prevent its combination with hydrogen

Ammonia may be combined with fulphur by mixing 386 together two parts of muriat of ammonia (ammonia of ammocombined with muriatic acid), two parts of lime, and nia. one part of fulphur, and diffilling; a yellow liquor is obtained, which contains sulphuret of ammonia. It is

capable of cryftallizing.

The phosphuret of ammonia is unknown.

Ammonia is capable of combining with leveral of the metallic oxyds, particularly copper.

It combines with fixed oils, and forms foap.

The order of its affinities is precifely the same with that of the fixed alkalies.

CHAP. V. Of ACIDS.

Substances possessed of the following properties are

1. When applied to the tongue they excite that fen- properties fation which is called four or acid.

They change the blue colours of vegetables to a The vegetable blues employed for this purpote are generally tincture of litmus and fyrup of violets or of radilhes, which have obtained the name of reagents or tests. If these colours have been previously converted to a green by alkalies, the acids restore them again.

3. They unite with water in almost any proportion. 4. They combine with all the alkalies, and most of the metallic oxyds and earths, and form with them those

compounds which are called neutral falts.

It must be remarked, however, that every acid does not possess all these properties; but all of them possess a sufficient number of them to distinguish them from other substances. And this is the only purpose which artificial definition is meant to answer.

Paracelfus believed that there was only one acid prin-

Acids. Theories about the acid prin-

ciple in nature which communicated tafte and folubility to the bodies in which it was combined. Beccher embraced the fame opinion; and added to it, that this acid principle was a compound of earth and water, which he confidered as two elements. Stahl adopted the theory of Beecher, and endeavoured to prove, that his acid principle was sulphuric acid; of which, according to him, all the other acids were mere compounds. But his proofs were only conjectures or vague experiments, from which nothing could be deduced. Nevertheless, his opinion, like every other which he advanced in chemistry, continued to have supporters for a long time, and was even countenanced by Macquer. At last its defects began to be perceived, Bergman and Scheele declared openly against it; and their discoveries, together with those of the French chemists, notwithstanding the ill-natured attempts of Monnet to support it, demonstrated the falsehood of both parts of the theory, by shewing that sulphuric acid did not exist in the other acids, and that it was not compoled of water

and earth, but of fulphur and oxygen.

The opinion, however, that acidity is owing to fome principle common to all the falts, was not abandoned. Wallerius, Meyer, and Sage, had advanced different theories in succession about the nature of this principle; but as they were founded rather on conjecture and analogy than direct proof, they obtained but Lavoisier's few advocates. At last Mr Lavoisier, by a number of ingenious and accurate experiments, proved, that feveral combustible substances when united with oxygen form acids; that a great number of acids contain oxygen; and that when this principle is separated from them, they lofe their acid properties. He concluded, therefore, that the acidifying principle is oxygen, ,and that acids are nothing elfe but combustible fubstances combined with oxygen, and differing from one another according to the nature of the combustible base. This conclusion has been confirmed by every fublequent observation. All the acids hitherto analysed contain oxygen, one perhaps excepted, the Pruffic acid, which possesses properties so different from the rest, that it might, without great impropriety, be placed in a distinct class. It is probable, therefore, that those acids which it has not yet been possible to decompose consist of oxygen combined with a combustible base: but till this analysis has actually been accomplished, the theory of Mr Lavoisier cannot be considered as completely demonstrated (R).

Lift of the acids.

theory.

The acids at prefent known amount to about 39, most of which have been examined within these 30 years. Their names are as follows:

CALOR	A LICIA LIGHTICO CAL CO	O TOTICIALO "
	Sulphuric acid,	8. Phosphorous,
2.	Sulphurous,	9. Boracic,
3.	Nitric,	10. Fluoric,

24. Suberic,	37. Chromic,
25. Laccic,	38. Platinic,
26. Pyromucous,	39. Stannic,
27. Pyrolignous,	

These acids shall form the subject of the following fections.

SECT. I. Of Sulphuric Acid.

Sulphur combines with two different quantities of oxygen: with the smaller quantity it forms fulphurous acid; with the larger, fulphuric acid. The last of these is the subject of the present section.

The ancients were acquainted with fome of the com Different pounds into which fulphuric acid enters; alum, for in-of fulph stance, and green vitriol: but they appear to have been acid. ignorant of the acid itself. It is first mentioned in the works of Basil Valentine, which were published about

the end of the 15th century.

It was for a long time obtained by distilling green vitriol, a falt composed of sulphuric acid and green oxyd of iron; hence it was called cil of vitriol, and afterwards witriolic acid. Another method of obtaining it was by burning fulphur under a glass bell; hence it was called also oleum fulphuris per campanam. The French chemists in 1787, when they formed a new chemical nomenclature, gave it the name of fulphuric acid.

At present it is generally procured by burning a Meth mixture of fulphur and nitre in chambers lined with procur lead. The theory of this process requires no explanation. The nitre supplies a quantity of oxygen to the sulphur, and the air of the atmosphere furnishes the rest. The acid thus obtained is not quite pure, containing a little potals fome lead, and perhaps also nitric and sulphurous acids. These acids may be driven off by applying for some time a gentle heat, and afterwards the sulphuric acid itself may be distilled over pure.

It appears from an experiment of Mr Berthollet, lts a that sulphuric acid contains 63,2 parts of sulphur, and nent 36,8 of oxygen. He ascertained, in the first place *, * Mo that nitre is totally decomposed by being heated with Par. th of sulphur. He then mixed together 288 grains of 234 nitre and 72 of fulphur; and after exposing them to a sufficient heat, he found 12 grains of sulphur sublimed, and 228 grains of inlphat of potals +. But the + Me fum of the ingredients was 360 grains; confequently Par. 120 grains had been diffipated. All this loss mult have 603. been suffered by the acid of the nitre, for the heat was too finall to separate any of the alkali. According to Mr Kirwan, 288 grains of nitre contain 132,96 of alkali,

(R) This theory has been carried fo far by some chemists, that they have confidered it as a conclusive proof, that oxygen did not enter into the composition of a body, if they could shew that the body was not an acid. .Thus, according to them, water cannot contain oxygen, because water is not an acid. - But furely no theory, however ingenious and fatisfactory, can for a moment be put in competition with experiment. The ways of Lature are not as our ways, nor her thoughts as our thoughts.

proper-

lohuric kali, and 155,04 of acid. 155,04 - 120 = 35,04 = quantity of oxygen furnished by the nitre to convert ~

60 grains of fulphur into acid.

Sulphuric acid is a liquid, fomewhat of an oily confissence, transparent and colourless as water, without any (mell, and of a very ftrong acid tafte. When applied to animal or vegetable substances, it very foon deftroys their texture.

It always contains a quantity of water; part of which, however, may be driven off by the application of a moderate heat. This is called concentrating the acid. When as much concentrated as possible, its specific gravity is

It changes all vegetable blues to a red, except indigo. According to Erxleben, it boils at 5460; according

to Bergman, at 572°.

When exposed to a sufficient degree of cold, it crystallizes or freezes; and after this has once taken place, it freezes again by the application of a much inferior cold. Morveau froze it at - 40; it assumed the appearance of frozen fnow. Afer the process began it went on in a cold not nearly so intense. The acid melted flowly at 27,5°; but it froze again at the same temperature, and took five days to melt in the temperature of 43° 1. Chaptal, who manufactured this acid, once obferved a large glass veffel full of it crystallized at the temperature of 48°. These crystals were in groups, and confifted of flat hexahedral prisms, terminated by a fix-fided pyramid. They felt hotter than the fur-Journ. de rounding bodies, and melted on being handled *. Chap-lyf. xxxi. tal has observed, that sulphuric acid, in order to crystallize, must not be too concentrated. This observation has been extended a good deal further by Mr Keir. He found, that fulphuric acid, of the specific gravity of 1,780, froze at 450; but if it was either much more or much less concentrated, it required a much greater cold for congelation +.

Sulphuric acid has a very flrong attraction for water. Neumann found, that when exposed to the atmosphere it attracted 6,25 times its own weight. Mr Gould found, that 180 grains of acid, when exposed to the atmosphere, attracted 68 grains of water the first day, 58 the second, 39 the third, 23 the fourth, 18 the fifth, and at last only 5, 4, 3, 4, 3, &c. The 28th day the augmentation was only half a grain *. The

SUPPL. VOL. I. Part I.

affinity therefore between fulphuric acid and water, as Sulphuric is the case in general with other substances, becomes weaker the nearer they approach to faturation. He does not specify the specific gravity of his acid; but as it only attracted 3,166 times its own weight, it could not have been very concentrated.

When sulphuric acid is mixed with water, a great quantity of caloric is evolved. A mixture of equal parts of these liquids causes a heat almost equal to that of boiling water. Lavoisier and De la Place found, that when 2,625 lbs troy of fulphuric acid, of the specific gravity 1,87058, was mixed with 1,969 lbs. troy of water, as much caloric was evolved as melted 4,1226 pounds troy of ice, or as much caloric as the acid and water would have given out had they been heated without mixture to 155,90 +. This caloric is owing chiefly, + Mom. if not folely, to the increase of density in the water; for Par. 1780. when equal quantities of fulphuric acid and water are mixed together, the specific gravity is much greater than the mean; and it has been formerly shewn, that whenever bodies become denser they give out caloric.

Since there is fuch a strong affinity between sulphu-Strength of ric acid and water, and fince the denfity of the mixture fulphuric is different from the mean denfity of the ingredients, it rious denbecomes a problem of the greatest importance to deter-sities. mine how much of the strongest sulphuric acid that can be prepared exists in any given quantity of sulphuric acid of inferior specific gravity, and which consequently confilts of a determinate quantity of this strong acid diluted with water.

This problem has been folved by Mr Kirwan t. He t Triff took sulphuric acid of the specific gravity 2,000, which Trans. iv. is the strongest that can be procured, for his standard, and the point was to determine how much of this standard acid existed in a given quantity of acid of inferior density.

He concluded, from a number of experiments with fulphuric acid, of the specific gravities 1,8846, 1,8689, 1,8042, 1,7500 (for he could not procure an acid of the specific gravity 2,000 at the temperature of 60°, in which his experiments were performed), that when equal parts of flandard acid and water are mixed, the denfity is increased by 1/15th part of the whole mixture. Then, by applying a formula given by Mr Poujet (s), he calculated, that the increase of density, on mixing

(s) Mr Poujet undertook the examination of the specific gravity of alcohol mixed with different quantities of water. He took for his standard alcohol whose specific gravity was 0,8199, at the temperature of 65,75°. He then formed ten mixtures; the first containing nine measures of alcohol and one of water, the second eight meafures of alcohol and two of water, and fo on till the last contained only one measure of alcohol and nine of water. He took care that each of these measures should contain equal bulks, which he ascertained by weight, obferving that a measure of water was to a measure of alcohol as 1 to 0,8199. Thus 10000 grains of water and 8199 of alcohol formed a mixture containing equal bulks of each. From the specific gravity of each of these mixtures he discovered how much they had diminished in bulk in consequence of mixture, by the following method.

Calling A the real specific gravity of any of the mixtures; B its specific gravity found by calculation, suppoling no diminution of bulk; n the number of measures composing the whole mass; $n-\alpha$ the number to which it is reduced in confequence of mutual penetration—it is evident, fince the increase of density does not diminish the weight of the whole mass, that $n = n - n \times A$. Therefore $n = n - n \times A$ Therefore $n = n - n \times A$. Therefore $n = n - n \times A$ and $n = n - n \times A$ are $n = n - n \times A$.

 $\frac{A-B}{A}$ is therefore the diminution of volume produced by the mixture.

sulphuric different quantities of standard acid and water, was as Acid. in the following table:

Number of Number parts of parts of fix water. dard acid		Augmenta- tion of den- fity.
5	95	0,0252
10	90	0,0479
15	85	0,0679
20	80	0,0856
25	75	0,0699
30	70	0,1119
35	65	0,1213
40	60	0,1279
45	55	0,1319
50	50	0,133.3

The first 50 numbers of the following table were formed by adding these augmentations to the specific gravity of the above mixture found by calculation, and taking the arithmetical mean for the intermediate quantities. The remaining numbers were formed from actual observation. He found by the first part of the table, that 100 parts of acid, of the specific gravity 1,8472, contained 88,5 parts standard, consequently

400 grains of this acid contain 354 grains standard. He Sulphuric took fix portions of this acid, each containing 400 grains, and added to them as much water as made them contain respectively 48, 46, 44, 42, 40, 38 grains standard. The quantity of water to be added in order to produce this effect, he found by the following method. Suppose x = the quantity of water to be added to 400 parts of acid, that the mixture may contain 48 per cent. of standard acid. Then 400 + x: 354::100:48, and consequently x = 337,5. After finding the specific gravity of thefe, the half of each was taken out, and as much water added; and thus the specific gravities, corresponding to 24, 23, 22, 21, 20, 19, were found. Then fix more portions, of 400 grains each, were taken, of the specific gravity 1,8393, and the proper quantity of water added to make them contain 36, 34, 32, 30, 28, 26 per cent. of standard. Their specific gravities were found, the half of them taken out, and as much water added; and thus the specific gravity of 18, 17, 16, 15, 14, and 13 found. Care was taken, after every addition of water, to allow the ingredient sufficient time to unite.

The last 11 numbers were only found by analogy; observing the series of decrement of the four last numbers before them.

TABLE

The following table contains the refult of Mr Poujet's experiments, calculated according to that formula; the whole volume or n being = 1.

Meafures of Water. Alcohol.		Diminution of the whole vo- lume = 1 by experiment.	By calculation.
1	9	0,0109	0,0103
2	8	0,0187	0,0184
3	7	0,0242	0,0242
4	6	0,0268	0,0276
5	5	0,0288	
6	4	0,0266	0,0276
7	3	0,0207	0,0242
8	2	0,0123	0,0184
9	I	0,0044	0,0103

It is evident, from this table, that the diminution of the bulk of the mixture follows a regular progression. It is greatest when the measures of water and alcohol are equal, and diminishes as it approaches both ends of the series. Mr Poujet accounts for this by conceiving the alcohol to be dissolved in the water, which retains a part of it in its pores, or absorbs it. The quantity absorbed ought to be in the ratio of that of the solvent and of the body dissolved, and each measure of water will retain a quantity of alcohol proportional to the number of measures of alcohol in the mixture. Thus in a mixture formed of nine measures of alcohol and one of water, the water will contain a quantity of alcohol = 9; in one of eight measures of alcohol and two of water, the water will contain a quantity of alcohol = 8. Therefore the diminution of bulk in each mixture is in a ratio compounded of the measures of alcohol and water which form it; in the above table, as 1×9 , 2×8 , 3×7 , 4×6 , &c. And in general, taking the diminution of bulk when the measures of both liquids are equal for a constant quantity, and calling it ϵ , calling the number of measures n, the number of measures of alcohol κ , the increase of density

But we have no reason to suppose that sulphuric acid, Sulphuric at the density 2,000, is free from all mixture of water;

Acid.

Acid.

Acid.

Acid.

Acid. confiderable proportion; for when it is combined with Quantity other bodies, barytes, for instance, or potass, there is a of real acid considerable quantity of water which remains behind, in strong and does not enter into the combination. Now, is it acid. possible to determine what would be the density of fulphuric acid, supposing it to be deprived of all water, or at least of all water except what is necessary for its existence as an acid? or to determine, how much real acid exilts in a given quantity of standard acid?

Homberg first attempted to answer this question. It was afterwards undertaken by Bergman, and Wenzel, and Wiegleb. They do not inform us of the quantity of water contained in a given weight of acid, but they put it in our power to find it, by informing us how much real acid is necessary to saturate a given quantity of potals. Their respective experiments give the fol-

lowing numbers:

Homberg used carbonat of potass, and did not take into confideration the carbonic acid driven off by the fulphuric. When this is taken in, his number should

be 54 instead of 38,3.

Now to discover the quantity of real acid in any fulphuric acid mixture, we have only to find out how much potafs it would require for faturation. The differences between the above refults are so great, that there was reason to suspect their accuracy. Mr Kirwan therefore attempted to afcertain the denfity of pure fulphuric acid by another method, and he rated it at 4,226. As this method has been already described in the article CHEMISTRY (Encycl.), we cannot enter upon it here. At any rate, it would be unnecessary, as many of the principles upon which Mr Kirwan went were erroneous, as Mr Morveau* and Mr Keirt have fufficiently shewn; * Encycl. and Mr Kirwan with his usual candour has accord- Method art. ingly abandoned it, and adopted another method which Affinite. is not liable to the same exceptions. He dissolved 1523,5 Didionary,

denfity or diminution of bulk z; we shall have $c:z::\frac{n}{2}\times\frac{n}{2}:\overline{n-x}\times x$, and $z=\frac{4c}{n^2}\times\overline{nx-x^2}$, or (making

n = 1) = $4 c \times - 4 c \times^2$. The diminution of bulk, calculated according to this formula, make the last column of the above table. They correspond very well with experiment, while the measures of alcohol are more than those of water, but not when the reverse is the case. This Mr Poujet thinks is owing to the attraction which exists between the particles of water, and which, when the water is confiderable compared with the alcohol, refifts the union of the water with the alcohol.

By the formula $z = \frac{4 c n x - 4 c x^2}{n^2}$, the quantity of alcohol of the flandard may be determined in any mix-

ture where the alcohol exceeds the water.

Let the number of measures, or the whole mass The measures of alcohol

The diminution of bulk at equal measures The diminution of bulk of a mixture containing x measures of alcohol = 40x - 400°

The specific gravity of water

The specific gravity of the alcohol The specific gravity of the unknown mixture

Then

Sulphuric grains of pure carbonat of potals, dried in a red heat, in distilled water. The whole weighed 4570 grains. He took 360 grains of this mixture, which contained 120 grains of carbonat of potals, and faturated it with pure fulphuric acid of the specific gravity 1,565, which, according to the above table, contained 61 per cent. of flandard acid. The acid required for faturating the folution of potals amounted to 130 grains, and contained therefore 79 of standard. The carbonic acid disengaged was 34 grains, and confequently the quantity of alkali was 120 — 34 = 86 grains. The folution being turbid, was diluted with 3238 grains of water. Its specific gravity was then 1,013 at the temperature of 60°. The weight of the whole was 3694 grains. Fortyfive grains of fulphat of potals (potals combined with fulphuric acid) diffolved in 1017 grains of diffilled water, have the same specific gravity at the same temperature; from whence it follows, that the proportion of falt in each was equal. But in the last folution the quantity of falt was $\frac{1}{23,6}$ of the whole; therefore the quantity of falt in the first was $\frac{3694}{23,6} = 159,52$ grs. Now of this weight 86 grains were alkali; the remainder, therefore, which amounts to 70,52 grains, must be acid. But the quantity of standard acid employed was 79 grains; of this there were 81 grains, which did not enter into the combination, and which must have been pure water: 79 parts of standard acid, therefore, contain at least 8,5 parts of water, and consequently 100 parts of standard acid contain 10,75 parts of water. It only remains now to confider how much water fulphat of potals contains. Mr Kirwan thinks it contains none, because it loses no weight in any degree of heat below ignition, and even when exposed to a red licat for half an hour it hardly loses a grain. This is certainly sufficient to prove, at least, that it contains very little water; and confequently we may conclude, with Mr Kirwan, that 100 parts of fulphuric acid, of the specific gravity 2,000, are composed pretty nearly of 89,25 of pure acid and 10,75 of water. This method used by Mr Kirwan is nearly the same with that proposed by

It feems even possible to obtain fulphuric acid free from all the water that may not be necessary to its acid state. When it is procured by distillation from green vitriol, if the receiver be changed after the process has gone on for some time, a quantity of acid is obtained in a

folidform, or crystallized. This, as Morveau has shewn, is Sulphuric fulphuric acid deprived of the water with which it is usually combined. When this glacial acid, as it has been called, is exposed to the air, it rites in white fumes, and is foon diffipated. This fingular effect is produced by its violent attraction for the water which exists in atmospheric air. When thrown into water, it feizes it with violence; a great deal of caloric is evolved, fufficient, if the quantity of water be not too great, to elevate the whole in vapours +.

Sulphuric acid is capable of decomposing alcohol and Method. oils; and when affifted by heat, it decomposes also some 590. of the metallic oxyds which contain the greatest quantity of oxygen; as red oxyd of lead, black oxyd of man- Action of ganesc. It decomposes likewise all the sulphurets and this acid phosphurets which have an alkaline or earthy basis.

It oxydates iron, zinc, and manganese, in the cold. By the affiftance of heat it oxydates filver, mercury, copper, antimony, bifmuth, arfenic, tin, and tellurium. At a boiling heat it oxydates lead, cobalt, nickel, molybdenum. It does not act upon gold, placinum, tungsten, nor titanium.

It unites readily with all the alkalies, the alkaline earths, alumina, and jargonia, and with most of the metallic oxyds, and forms falts denominated fulphats. Thus the combination of sulphusic acid and soda is called sulphat of foda; the compound of sulphurie acid and lime, fulphat of lime, and so on. It does not act upon filica

The affinities of fulphuric acid are as follows :: Barytes,

Strontites *, Potais, Soda, Lime, Magnefia, Ammonia, Alumina, Jargonia †? Oxyd of zinc, -- manganefe, --- cobalt, - nickel, ----- lead, ____ tin, copper, - bitmuth,

Its affinities. \$ See Bergman and Lavoisier. * Dr Hope, Tranf. Edin.

Oxyd

Then fince the increase of density does not change the weight of the whole, $1-x \times a + b \times a = 0$ $1 - 4cx + 4cx^2 \times y.$

Hence
$$x = 0.5 - \frac{a-b}{8cy} + \sqrt{\frac{a-y}{4cy} + (\frac{a-b}{8cy} - 0.5)}$$

$$y = \frac{a-ax+bx}{1-4cx+4cx^2}$$
And making $a = 1$, $b = 0.8199$, $c = 0.0288$

$$x = 0.5 - \frac{0.1801}{0.2304y} + \sqrt{\frac{1-y}{0.1152y} + (\frac{0.1801}{0.2304y} - 0.5)}$$

$$y = \frac{1-0.1801x}{1-0.1152x + 0.1152x^2}$$

SECT. II. Of Sulphurous Acid.

Sulphurous acid is composed of fulphur and oxygen combined: the proportions have not been afcertained; but the fact itself, and that the quantity of oxygen is less than what enters into sulphuric acid, has been proved beyond the possibility of doubt. Neither can it be doubted, though the fact has not been attended to, that in this acid the fulphur and oxygen mutually faturate each other; and that fulphuric acid is not composed of fulphur and oxygen, but of fulphurous acid and oxygen. Phofphorus is capable of decomposing fulphuric acid by the ashistance of heat, of seizing a quantity of its oxygen, and converting it into fulphurous acid; but upon fulphurous acid it has no effect whatever *. The affinity of phofphorus, therefore, for oxygen is less than that of fulphur; yet it is capable of taking oxygen from fulphuric acid. Is it not evident from this, that sulphunic acid is composed of fulphurous acid and oxygen? and that fulphur has a stronger affinity for oxygen than fulphurous acid has? For if both the acids were composed directly of sulphur and oxgen, it would follow from experiment, that the affinity of phosphorus for oxygen was both stronger and weaker than that of fulphur; which would be abfurd.

Sulphurous acid has been known fince the time of Stahl. Scheele first discovered the method of obtaining it in quantities; and Dr Priestley first procured it in a flate of purity; for Scheele's acid was diffolved in
